OXFORD.

O'XFORD, an ancient and famous city and seat of learning in England, the chief town of the county of Oxford, is situated on the north-east bank of the Isis, a tributary of the Thames, a little above the point where it is met by the Cherwell. Both streams are crossed by numerous bridges, of which the finest are Folly Bridge over the Isis, and Magdalen Bridge over the Cherwell. Lat. of the city, $51^{\circ} 45' 55''$ N., long. $1^{\circ} 15' 29''$ W. Distance from London, 55 miles W.N.W. Pop. (1871) 34,482; (1881) 40,862. O. occupies an undulating site, is surrounded by rich and wooded meadows, and presents to the eye of the approaching visitor a scene of unequalled architectural magnificence—spires, and towers and domes rising as thickly as chimney-stalks in the manufacturing towns of Lancashire or Yorkshire. The four main streets of O. meet at right angles near the center of the town, at a place still called Carfax, a corruption of *Quatre voies*, and which appears in Agas's map (*temp.* Elizabeth) as *Cater voys*. These are—Cornmarket Street, leading into St. Giles's, and running due north; Queen Street, leading to the railway-stations, and running west; St. Aldate's Street, leading to the Isis, and running due south; and High Street, which is the chief street of the city, gracefully curving in an easterly direction, and conducting to the river Cherwell, a smaller river joining the Isis soon after it has passed Oxford.

The western half of the town is the most uninteresting; and it is a misfortune that the railway-stations are placed here, as travelers, on arriving, are introduced to the meanest parts of the city first. The county courts and jail, and the remains of the castle, from which the Empress Maud escaped while it was besieged by King Stephen, will be observed in passing. There is one good street in this part—viz., Beaumont Street, built on the site of the ancient Beaumont Palace, in which Richard I. was born. At the end of this street is Worcester College. Passing to the north from Carfax, along the Cornmarket, the old tower of St. Michael's Church is seen, against which stood formerly the north gate of the city; next St. Mary Magdalen Church; then the Martyr's Memorial, with the Taylor Buildings and Randolph Hold on the left, and part of Balliol College and St. John's College on the right. St. Giles's Church is at the north end of this street, which is very wide, and has a row of elm-trees on each side, forming a picturesque avenue like a foreign *boulevard*. Beyond this, to the north, is the Radcliffe Observatory and Infirmary. The High Street is about 1000 yards in length; it is reckoned one of the noblest streets—architecturally considered—in Europe, and contains, among other edifices, part of the buildings of Magdalen College, Queen's College, All-Souls' College, University College, and St. Mary's and All-Saints' Churches. Parallel to it is Broad Street, in which are situated Balliol, Trinity, and Exeter Colleges, the Ashmolean Museum, the Clarendon Rooms, the Sheldonian Theater, and close by are the Academical Schools, the Bodleian Library, and the Picture Gallery. In St. Aldate's Street, which

forms the southern part of the series of streets already mentioned as forming one line, and running north and south, is Christ Church College (the entrance tower of which contains the great bell 'Tom of Oxford,' weighing upwards of 17,000 lbs.) and St. Aldate's Church. The other colleges and important buildings connected with the University of O. lie back from the principal streets.

To attempt particularizing the architectural characteristics of each of these edifices is impossible within our limits. It may suffice to say, that though there is nothing extraordinarily fine about the architecture of the colleges, regarded individually, yet the vast number of the structures and variety of styles present a *tout-ensemble* that is altogether sublime. The effect is wonderfully heightened by the interspersing of gardens, meadows, and venerable trees—old as the buildings that tower above them. Christ Church is celebrated for its magnificent hall, picture gallery, and library, as well as for its extensive grounds; its chapel, the cathedral church of O., is Norman in style, but is inferior, both in size and beauty, to most English cathedrals. Merton College is situated a little to the south of the High Street, and still retains the original chapel and part of the other buildings erected by Walter de Merton in the 13th century. Magdalen College retains its celebrated cloister and tower of the 15th c., and the buildings here are the most complete of any college in Oxford. Oriel College, a comparatively modern structure, is very picturesque, but far from chaste in its design; New College ranks among the noblest buildings in the city—the chapel, the hall, the cloisters, the groined gateways, and even some original doors and windows remain, in their exterior at least, as they came from the hand of their master architect, William of Wykeham, 500 years ago; Queen's College is built in the Grecian style of architecture, with a spacious and handsome chapel and a fine library; so is Trinity College; University College is a not unpleasing mixture of Gothic and Italian; Exeter College has a splendid frontage on the west, and its chapel (built 1857–1858), in the Gothic style, is the finest modern building in the city; it has also an excellent hall, and a beautiful library; Balliol College has a remarkably fine chapel, built only a few years ago.

Among the other churches in O., besides the cathedral church and the college chapels, are—St. Mary's, which is attended by the members of the university; St. Martin's, the church of the corporation of O.; St. Peter's-in-the-East, with a Norman crypt; St. Michael's, with a Saxon tower; and St. Aldate's. The chief buildings connected with the university, besides the Bodleian and the Ashmolean Museum already mentioned, are the Radcliffe Library, a circular structure, adorned with Corinthian columns and surmounted by a dome; the Radcliffe Observatory, crowned by an octagonal tower; the University Printing-office, and the Taylor Institution, founded 'for the teaching the European languages.' The Botanic Gardens are nearly opposite Magdalen

Oxenage. Other notable buildings are—the Town Hall, the Radcliffe Infirmary, the County Gaol, and one or two dissenting places of worship, including a Wesleyan and an Independent Chapel. Lady Margaret Hall and Somerville Hall, founded in 1879 for lady students taking advantage of the lectures of the Oxford association for promoting the higher education of women, are not as closely connected with the university. O. is a mart for the disposal of the agricultural produce of the neighboring country, but has little trade of its own, and is dependent for its prosperity chiefly on the university. It is a municipal and parliamentary borough, and governed by a mayor, nine aldermen, and thirty councillors, whose jurisdiction, however, does not embrace the university. The university sends two members to parliament; the city sent two also, but was disfranchised for bribery from 1883 to 1890.

O., by the Saxons called *Oxnaforð*, and in *Domesday Book*, *Oxeneford* (probably 'a ford for oxen'), is a place of great antiquity. The date of its origin is unknown, but as early as the 8th c. there was a nunnery established here; and in 802, an act of confirmation by Pope Martin II. describes it as an ancient seat of learning. It is said to have been a residence of King Alfred, and also of Canute, who held several parliaments within its walls. The townsmen closed their gates against William the Conqueror, who stormed the town in 1067, and gave it to one of his followers, Robert d'Oyley, who built a castle here to overawe the disaffected Saxons, some ruins of which are still to be seen. The pacton that terminated the strife between Stephen and Henry II. was drawn up at Oxford. In the reign of Edward III., the preaching of Wickliffe excited great commotion among the students, and threatened well-nigh the dissolution of the university. In the reign of the 'Bloody Mary,' it witnessed the martyrdoms of Ridley, Latimer, and Cranmer; and during the great civil war of the 17th c., it was for a while the head-quarters of the Royalist forces, and was conspicuous for its adherence to Charles I. Ever since that period the city—or, at any rate, the university—has been in general characterized by an extreme devotion to the 'church' and the 'king.'

OXFORD UNIVERSITY is said to have been founded by King Alfred. Without claiming for it an origin quite so ancient, it is certain that from very early times students resorted to Oxford in order to attend lectures there delivered by learned men, and that they lived in the houses of the townspeople. In some cases they combined together, so as to secure the service of a common teacher, with whom they lived in a large tenement called an inn, hostel, or hall. For a long time, however, the great majority of the students lodged in rooms hired from the citizens; and as late as the year 1512, regulations were made for the governance of such students. As their numbers increased, the halls were multiplied. Anthony Wood states that he could show the names and places of more than a hundred. A great diminution in the numbers of the students took place about the middle of the 15th century. This, among other causes, led to the gradual disappearance of the halls, which were bought up by the wealthier colleges. Only five of the halls now exist, which differ from the colleges only in that they are unincorporated, and have little or no endowments. Residence in private lodgings had also fallen into disuse; and by the time of Queen Elizabeth, it had become a compulsory rule that all undergraduates should reside in some college or hall, at least for the first twelve terms of residence. Now, however, undergraduates may in most colleges live in lodgings from the beginning of their course.

The colleges were founded at various periods, from the end of the 13th c. to the beginning of the 18th. Fourteen out of the 20 were founded before the Reformation. Their object originally was to support limited societies of students, who were to devote their lives to study—by no means, as at present, to educate large classes of the community. Students, other than those on the foundation, seem not to have been regarded by the founders as an essential part of the college. The colleges arose, as has been already said, partly instead of the old halls, and were partly at first connected with the monasteries, it being by means of these institutions that benevolent persons were enabled to give permanent support to poor secular scholars. University and Balliol, which now rank as the oldest colleges, were in point of fact halls supported by endowments held in trust for the maintenance of their students. The originator of the collegiate system, in anything like its present form, was Walter de Merton, who besides having founded Merton College, is entitled to the honor of having mainly contributed to fix the university in its present site. All those on the foundation of the colleges before the Reformation were called Clerici. The great majority of the fellows were required to take priest's orders within a certain period after their election. This requirement of course involved celibacy, which, besides, was expressly imposed in some colleges; and practically, in old times as now, was enforced by the rule of life and the obligation of residence. Within the last few years, in some of the

colleges the restriction of celibacy has been, under certain conditions, remitted in the case of fellows engaged in college work.

Under a statute passed in 1668, any person may now become a member of the university, without becoming a member of a college or hall, provided he satisfies certain disciplinary requirements. For such purposes these unattached students are under the control of a board of delegates; but no special provision is made for their instruction. In 1871, the new foundation of Keble College, built in memory of John Keble, was admitted to enjoy the same privileges (save as regards the academical status of its head) as are possessed by the existing colleges and halls.

Previous to the statute 17 and 18 Vict. c. 81, the constitution of the university was as follows: 1. The Hebdomadal Board, or Weekly Meeting, consisting of the Heads of Houses and the two Proctors, which body exercised the chief share of the administration of the university, and possessed the exclusive power of initiating legislation; 2. Congregation, consisting of certain university dignitaries, which met merely for the purpose of conferring degrees; 3. Convocation, consisting of all Masters of Arts, a body whose consent was necessary before any of the measures proposed by the Hebdomadal Board could become law, which elected the chancellor, the two representatives of the university in parliament, several of the professors, and dispensed the ecclesiastical patronage of the university. The statute referred to introduced important changes. The Hebdomadal Board has been changed into the Hebdomadal Council, consisting of the chancellor, the vice-chancellor, the proctors, six heads of houses, six professors, and six members of convocation of not less than five years' standing—such heads, professors, and members of convocation being elected by congregation, and holding office for six years.

Congregation, again, now consists of all the great officers of the university, the professors, public examiners, and all resident masters; and on this body is now bestowed the power of accepting or rejecting, and of amending any statute framed by the Hebdomadal Council. The composition and powers of Convocation remain unchanged. The students not on the foundation are for the most part commoners. In Worcester College and the halls there is still a class of fellow-commoners, who pay larger fees and enjoy certain privileges. They mainly consist of men above the ordinary age of undergraduates, who wish to have the intellectual advantages of the university without being subjected to the common routine of discipline. All other formal distinctions due to wealth or poverty are almost entirely abolished; such as the special privileges of peers, and the regard had to the poverty of candidates in the case of certain scholarships. It is very difficult to ascertain the actual number of students at any one time in Oxford, but now it is probably seldom above 1800.

There are four terms in each year—viz., Michaelmas Term, which begins on the 10th of October and ends on the 17th December; Hilary Term, which begins on the 14th of January and ends the day before Palm Sunday; Easter Term, which begins on the Wednesday in Easter-week, and ends on the Friday before Whitsunday; Trinity Term, which begins on the Saturday before Whitsunday and ends on the Saturday after the first Tuesday in July. Full Term, as it is called, does not begin till the first day of the week after the first congregation is held. By undergraduates, Michaelmas and Hilary Terms are kept by six weeks' residence, and Easter and Trinity Terms by three weeks each; but more than this is required by most of the colleges. Twenty-four weeks may be taken as the ordinary length of the academic year. Twelve terms of residence are required for the degree of B.A. from all.

The degree of M.A. is obtainable in the twenty-seventh term after matriculation. By a statute passed in 1850, the following examinations were made necessary for a degree in arts; but their nature has been considerably changed by the new statutes which came into effect 1878–1874: 1. Responsions, called 'Little Go' or 'Smalls' in the familiar language of undergraduates, are obligatory upon all. The university does not, as to this or any other pass examination, fix a limit of time within which they must be passed; but most colleges require their members to pass responsions, at least within their first year of study. Subjects: one Latin and one Greek author—or portions of them, as five books of Homer, five of Virgil, two Greek plays, &c.—with a paper of grammatical questions; a piece of English to be translated into Latin; two books of Euclid, or algebra up to simple equations inclusive; and arithmetic. 2. The First Public Examination, or Moderations, is also obligatory upon all. Candidates must have entered upon their fourth term. Subjects: the Four Gospels in Greek (except in the case of persons not members of the Church of England, when some one Greek author is to be substituted); one Greek and one Latin author, not the same as those offered for responsions, and one must be a poet, the other an orator; a piece of English into Latin, and a paper of grammatical questions; logic, or Euclid III. and IV., 1–9, and algebra. Honors are awarded at this examination both in classics and pure mathematics.

ics. Candidates are recommended to take up especially poets and orators. Verses, as well as Greek and Latin prose-writing, and a paper of grammatical and philological questions, are set. In the mathematical school, which in this examination exists as a separate school for honors only, candidates are examined in pure mathematics up to the Integral Calculus and the Calculus of Finite Differences inclusive.

3. The Second Public Examination, held twice a year, to be passed not earlier than the 12th term, and for honors not later than the 16th term of standing; unless the candidate has been classed in some other school of the Second Public Examination, in which case he may be admitted up to the 20th term inclusive. This examination consists of three parts: (1.) an examination in the rudiments of faith and religion, or in the case of those who (or whose guardians) object to such examination, certain substituted books or subjects; (2.) an examination of those who do not seek honors; and (3.) an examination of those who do seek honors. In this last there are, in Oxford phraseology, six schools: *Literæ Humaniores*, Mathematics, Natural Science, Jurisprudence, Modern History, Theology. Candidates are entitled to a degree of B.A. who, having passed the two previous examinations, also passed the examination appointed for those who do not seek honors, or who obtain honors in any one of the six honor-schools. But every candidate, except he has obtained honors in the Theology School, must have satisfied in the rudiments of faith and religion or the substitute. By these rudiments are understood the Old and New Testaments (Gospels and Acts of the Apostles in the original Greek); and the 39 articles. The pass examination embraces subjects chosen from at least two out of the three following groups: (a) Greek and Roman history and philosophy; (b) English modern languages, political economy, and law; (c) geometry, mechanics, chemistry, and physics. Out of these the candidate must select three subjects, one of which must be either (1) ancient philosophy and history (in the original Greek, or Greek and Latin); or (2) a modern language, (French or German). The classical books must be other than those offered for Responsions and Moderations. Candidates for honors may select any one, or more than one of the six schools. The most popular and influential of these is the school of *Literæ Humaniores*. The examination in this school includes (1) the Greek and Latin languages; (2) the histories of ancient Greece and Rome; (3) logic, and the outlines of moral and political philosophy. Candidates may also offer certain special subjects in any of these three departments. The republic of Plato and the ethics of Aristotle form the basis for philosophical study, though they are every year more largely supplemented by modern philosophy.

Next in the numbers of its candidates is the School of Modern History, which includes (1) the continuous history of England; (2) general history during some period, selected by the candidate, from periods to be named from time to time by the Board of Studies; (3) a special portion of history, or a special historical subject, carefully studied with reference to original authorities. The School of Jurisprudence includes (1) general jurisprudence; (2) the history of English law; (3) some department of Roman, and it may be, of English law; (4) international law, or a specified department of it. The School of Mathematics embraces pure and mixed mathematics (algebra, trigonometry, calculus, mechanics, optics, astronomy). The School of Natural Science has a double examination for honors—a preliminary and a final. The preliminary examination, incumbent upon all, is restricted to the elementary parts of mechanics, physics, and chemistry. In the final examination, the candidate may offer himself for examination in one or more of the three general subjects of physics, chemistry, and biology. The examination in the Honor School of Theology includes the Holy Scriptures, dogmatic and symbolic theology, ecclesiastical history and the fathers, the evidences of religion, liturgies, sacred criticism, and the archæology of the Old and New Testaments. A knowledge of Hebrew will have weight in the distribution of honors. The organization of these schools is at present the main function of the university, as distinct from the colleges. [Professorial teaching on its own account only exists to a very limited extent. In the main, the teaching power of the colleges is devoted to preparing their undergraduate members for these various examinations.]

Examinations also takes place for degrees in law, medicine, divinity, and music; but these are in great measure formal. The examinations for degrees in arts are the proper work of the university.

Besides these honors, various distinctions are conferred by the university. There are several university scholarships, more particularly the Vinerian law fellowships and scholarships; the Eldon law scholarship; one Sanscrit and two Hebrew scholarships yearly; two mathematical scholarships; the Hertford scholarship, for the encouragement of the study of Latin, and the Ireland and Craven scholarships, for the encouragement of the study of classics. There is also the Newdigate prize for the best composition in English verse; and the three chancellor's prizes for the best com-

position in Latin verse, Latin prose, and English prose; the Gaisford prizes for Greek composition; and the Arnold, Stanhope, and Marquis of Lothian's prizes for the best essays on an historical subject. But the great prizes are the scholarships and the fellowships. By the commissioners under 17 and 18 Vict. c. 81, these have been for the most part thrown open, and are now awarded after examination without restrictions as to kin or place of birth. At All-Souls, and also at St. John's College, since the labors of the commissioners, an attempt has been made to keep up the former exclusiveness. The scholarships, which are so numerous as to be within the reach of any young man of ability, range from £60 to £80 a year, with rooms free, which would go a considerable way towards defraying the expense of a university education. At the close of this education come the fellowships; and it has been calculated that when the arrangements of the commissioners are complete, there will be between 20 and 30 fellowships, mostly about £300 per annum, open yearly to competition.

Oxford is, of course, chiefly fed from the great English schools. A close connection subsists, by the terms of the foundation, between Winchester and New College, between Westminster and Christ Church, and between Merchant Taylors' and St. John's. For the nature of this connection, see under these colleges. A student desirous of going to Oxford, must apply to the Head of the College to which he wishes to belong. Application in former times had to be made early, as all the good colleges were filled up for several years in advance. But now that undergraduates are allowed by most colleges to live in lodgings from the first, a candidate can have no difficulty in securing admission even to a distinguished college at short notice. There is no university examination at matriculation; but all the good colleges have such an examination before they receive any one—the standard of the examination, of course, varying with the college. After being received into the college, the undergraduate is sometimes assigned to a college tutor, who exercises a special control over his reading; but he also attends the instruction of the other college tutors or lecturers, as the course of his studies may require. The cost of tuition varies at different colleges, but an average of £65 may be given as paid by the undergraduate during his whole career. This payment is at some colleges distributed over three, at others over four years. Besides this, almost every undergraduate finds it necessary, at some period before taking his degree, to read with a private tutor, whom he chooses for himself. Private tuition has grown to be quite an institution in Oxford, though not formally recognized. Many of the ablest young men, after taking their degree, remain in Oxford for a year or two, taking private pupils. In this way an undergraduate, even of a badly taught college, could secure the advantages of the best tuition. But during the last few years, the lecturers in different colleges have more and more combined and systematized their work; and thus to a slight extent obviated the need for private tuition.

Much discussion has taken place on the merits and faults of this system; but, on the whole, it must be allowed to be useful for the tutor, as clearing up and concentrating his knowledge, while, at least to undergraduates who read for honors (with a few rare exceptions), it may be considered as absolutely necessary. Private tutors usually charge £10 a term for three hours a week. Previous to 1832, the professoriate of Oxford was strictly ornamental. A great effort was then made to stir it into life, which has been partially successful. New professorships were created, and the endowments of old ones were increased by the commissioners, under 17 and 18 Vict. c. 81. But the former of these measures, at least, whatever it may have done for the interests of science, has produced but little effect on the undergraduates. They still limit their range of studies by the requirements of the examinations of the schools, and it were hard to expect them to do otherwise. But professorial teaching has undoubtedly become more popular in the ordinary branches of study. Lectures by the professors of Law and Modern History, of Moral Philosophy, Logic, Greek, and Latin, are felt to be useful, and are therefore well attended. Considerable changes in the university system were contemplated in 1881, in accordance with the reforms suggested by the university commissioners. Amongst other changes, it was proposed that professors should do more of the teaching, and that fellowships should be more numerous, of less value, and of shorter tenure than at present.

The expenses vary at different colleges, not only indirectly from the tone of the society, but even directly from the charges made for necessities. A man should be exceedingly comfortable at Oxford with £200 a year; on £150, he can manage with economy. There have been instances of men passing creditably through the university course on £100 a year; the necessary expenses do not exceed that sum. It appears that some unattached students cover their board, lodging, and tuition for about £45 a year. Discipline inside the college is maintained by the head of the house and the tutors; in the town and its neighborhood, by the proctors, who are university officers invested with great authority. As a rule, this authority is well exercised. According

to the *Universities Commission Report* (1874), the revenue of the colleges and university in 1871 was £413,000.

The following is a list of the colleges and halls as they rank in the university; an account of each will be found in its alphabetical place: University, Balliol, Merton, Exeter, Oriel, Queen's, New College, Lincoln, All Souls, Magdalen, Brasenose, Corpus Christi, Christ Church, Trinity, St. John's, Jesus, Wadham, Pembroke, Worcester, Keble, St. Mary Hall, Magdalen Hall, New Inn Hall, St. Alban Hall, St. Edmund Hall. To these may be added Charsley's Hall, being a private hall under the mastership of W. H. Charsley, in virtue of a statute passed in 1854, empowering any M.A. of a certain standing to open a private hall on his obtaining a license from the vice-chancellor. The Unattached Students now number upwards of 100; but the present system of university teaching is not very favorable either to their increase or progress.

Among the books which may be consulted are—Ayliffe's *History of Oxford*, Wood's *Annals*, the *University Calendar*, the *Report of the Royal Commissioners* for 1852, and the *Student's Handbook to the University of Oxford*.

OXFORD BLUES. See HORSE GUARDS, ROYAL.

OXFORD CLAY, the principal member of the Middle Oolite series, is a bed of stiff dark-blue or blackish clay, sometimes reaching a thickness of 600 feet. There occur in its lower portion in some places layers of tough calcareous sandstone, called Kelloway Rock, from a place in Wiltshire, where it is quarried. The O. C. lies beneath the plain on which Oxford is built, and extends south-west and north-east from the shore Weymouth to the fen lands south of the Wash, thence it may be traced through Lincoln into Yorkshire, until it disappears under the sea at Scarborough. The close packing of the fossils in the fine compact clay has caused them to be beautifully preserved; the shells frequently retain their iridescence, and even the softer parts of the cephalopods have sometimes left with tolerably clear definition their form in the clay. The fossils are, however, often filled with iron pyrites, which, on exposure to the atmosphere, readily decomposes and destroys all traces of the beautiful organism. The remains of chambered shells of the genera *belemnites* and *ammonites* are very abundant, and with them are associated other shells, interesting crustacea, and the species of fishes and reptiles which are characteristic of the oolite.

OXFORDSHIRE, an inland county of England, bounded on the S. by the River Thames, E. by Bucks, W. by Gloucester. Area, 472,717 acres. Pop. (1871) 177,975; (1881) 179,650. The surface, where it is not level, is undulating. In the north-west the hills rise in Broom Hill to 836 feet above sea-level, and in the south-east of the county are the Chiltern Hills (q. v.), rising near Nutfield to 820 feet in height. It is watered along its southern border by the Thames, and the other chief rivers are the Windrush, Evenlode, Cherwell, and Thame, affluents of the Thames. By means of the Oxford Canal, which joins the Thames at Oxford, the towns and districts lower down the river (Abingdon, Wallingford, &c.), are supplied with coal from the Leicestershire coal-fields. The soil is fertile; the state of agriculture is advanced, 417,606 acres being under crops, fallow, or grass, in 1881; and the county may be considered one of the most productive in the country. Three members are returned to the House of Commons for the county.

OXIDATION is the term applied to the union of any body with oxygen, the body being then said to be *oxidized*, and the resulting compound being termed an *oxide*. Many bodies possess the property of entering into several distinct combinations with oxygen. For example, manganese (Mn) forms no less than six such compounds—viz., MnO , Mn_2O_3 , Mn_3O_4 , MnO_2 , Mn_2O_7 , Mn_2O_8 , which represent different stages of oxidation.

OXIDES, METALLIC, are the most important of all the compounds of the metals, and in many cases occur naturally as abundant and valuable ores. They are divided by chemists into three classes—viz., (1) basic oxides or bases, (2) saline or indifferent oxides, and (3) acid oxides or metallic acids. The different oxides of the same metal usually afford illustrations of two, and not unfrequently of all three of these classes. Thus (to take the case of manganese referred to in the last article) the protoxide (MnO) is a powerful base, the red oxide (Mn_2O_3) is a saline or indifferent oxide, showing little tendency to combine either with acids or alkalies, while permanganic acid (Mn_2O_7) presents all the properties of an acid. As a general rule, the greater the number of atoms of oxygen which an oxide contains, the less is it disposed to unite with the acids; on the contrary, it frequently possesses acid properties, and then unites with bases to form salts. Protoxides generally are strong salifiable bases; they require one equivalent of a monobasic acid to form neutral salts. Sesquioxides are weaker bases; their salts are usually unstable; they require three atoms or equivalents of a monobasic acid to form a salt which is neutral in composition, though it may not be neutral to test-paper; and in

general, all oxides require as many equivalents of acid as they contain atoms of oxygen in their composition. Some of the metallic acids, like the stannic and titanin, contain two atoms of oxygen to one atom of metal, but most of them contain three atoms of oxygen—such, for example, as the manganic, ferric, chromic, tungstic, molybdic, and vanadic acids; whilst in a few cases, such as the arsenic, antimonin, and permanganic, the proportion of oxygen is still higher.—Miller's *Inorganic Chemistry*, 2d edit. p. 314.

Of the basic oxides, which form by far the most important class, it may be observed that they are devoid of all metallic appearance, and present the characters of earthy matters, and that six only of them are soluble in water to any considerable extent—viz., the three alkalies, and baryta, strontia, and lime. All the oxides are solid at ordinary temperatures, and as a general rule, the addition of oxygen to a metal renders it much less fusible and soluble; the protoxide of iron, the sesquioxide of chromium, and molybdic acid being the only oxides that melt more readily than the metal.

OXLEYA, a genus of trees of the natural order *Cedrelaceae*, of which one species, *O. xanthoxyla*, the YELLOW WOOD of Eastern Australia, is a very large tree, 100 feet high, valuable for its timber.

OXUS, the ancient name of a great river in Central Asia, which is called by the Turks and Persians JIHUN, and AMU or AMU-DARIA by the natives of the country through which it flows. The O. rises in Lake Sari-kol, in the elevated plateau which separates Eastern and Western Turkestan. It flows through Buddakshan, Bokhara, and Khiva, and empties itself by several mouths into the Sea of Aral. In the first part of its course, its volume is increased by numerous affluents, but it receives no tributaries after entering Khiva, from which point its course is wholly through a dry sandy desert. Its total length is about 1150 miles. The value of the Oxus for the purpose of water communication, is said by recent Russian geographers to have been much overrated in Europe; and they add that in summer, vessels of even slight draught could only be got upon the stream by shutting off the irrigation canals, and risking the desolation of the country dependent on them for its crops. The true value of the Oxus lies in the means it will supply of irrigating the sterile alluvial wastes through which it runs.

Before the Christian era, it is believed that the Oxus flowed into the Caspian, and that since 600 A.D. it has twice changed its course (see ARAL). A great part of the old bed of the Oxus has recently been explored by M. Stebnutzki (*Bulletin de la Soc. de Géogr. de Paris*, April 1871), who has ascertained that it has a fall towards the Caspian, from which he infers that its course was not changed by an upheaval of the Turcoman desert, but by the simple accidents of fluvial action on an alluvial soil. In his address to the London Geographical Society in May 1872, Sir Henry Rawlinson said the restoration of the Oxus to its old bed was then under the serious consideration of the Russian government, that it was a work of no engineering difficulty whatever, and would assuredly be accomplished as soon as the neutrality of Khiva was secured.—See *A Journey to the Source of the Oxus*, by John Wood, with Essay of the Geography of the Oxus Valley by Colonel Yale, 1873; also *The Road to Merv*, by Sir H. Rawlinson, in the Proceedings of the Geog. Society, 1879.

OXYACIDS. When Lavoisier, in 1789, gave the name of oxygen to the *Dephlogisticated Air* discovered, in 1774, by Priestley, he believed that the presence of that body was essential to the existence of an acid, and this view was supported by the composition of the principal acids which were then known, such as sulphuric, nitric, carbonic, and phosphoric acids. But, by degrees, acids were discovered into which no oxygen entered, but which always contained hydrogen, and hence acids were divided into two great classes, the *oxyacids* and the *hydroacids*; oxygen being supposed to be the acidifying principle in the former, and hydrogen in the latter. At the present day, scientific chemists usually restrict the term *acid* to compounds into which hydrogen enters, and the acids are regarded as salts of the last named element; thus sulphuric acid (HO_2SO_4) and nitric acid (HO_2NO_3) are the sulphate and nitrate of oxide of hydrogen; hydrochloric acid (HCl) is chloride of hydrogen, &c.

OXYCHLORIDES, chemical compounds containing both chlorine and oxygen in combination with some other element or radical. Chloride of lime ($CaOCl$), chloride of potash ($KOCl$), oxychloride of lead or Turner's yellow belong to this class.

OXYGEN (symb. O, equiv. 8; new system, 16—see CHEMISTRY.—sp. gr. 1.1056) is a colorless, inodorous, tasteless gas, long regarded as a 'permanent' gas, but liquefied by Pictet of Geneva for the first time in 1877. Its chemical affinities for other elementary substances are very powerful; with most of them it is found in combination, or may be made to combine, in more than one proportion; with several in 4, 5, or 6 proportions; and there

is only one element (fluorine) with which it does not enter into any combination. Owing to the intensity with which many of these combinations take place, this gas has the power of supporting Combustion (q. v.) in an eminent degree. Of all known substances, it exerts the smallest refracting power on the rays of light. It possesses weak but decided magnetic properties, like those of iron, and like this substance, its susceptibility to magnetization is diminished or even suspended by a certain elevation of temperature. It is only slightly soluble in water; 100 cubic inches of that liquid dissolving 4.11 cubic inches of gas at 32°, and only 2.99 inches at 59°.

Oxygen gas is not only respirable, but is essential to the support of animal life; and hence it was termed *vital air* by some of the older chemists. A small animal placed in a bell-glass containing pure oxygen will not be suffocated so soon as if it were placed in the same glass filled with atmospheric air. For further details on this property of oxygen, the reader is referred to the article RESPIRATION.

Oxygen is the most abundant and the most widely distributed of all the elements. In its free state (*mixed* but not *combined* with nitrogen), it constitutes about a fifth of the bulk, and considerably more than a fifth of the weight of the atmosphere. In combination with hydrogen, it forms eight-ninths of all the water on the globe; and in combination with silicon, calcium, aluminium, &c., it enters largely into all the solid constituents of the earth's crust; silica in its various forms of sand, common quartz, flint, &c.—chalk, limestone, and marble—and all the varieties of clay, containing about half their weight of oxygen. It is, moreover, found in the tissues and fluids of all forms of animal and vegetable life, none of which can support existence independently of this element.

There are various modes of obtaining oxygen, the simplest of which consists in the exposure of certain metallic oxides to a high temperature. It was originally obtained by its discoverer, Dr. Priestley, from the red oxide of mercury, which, when heated to about 750°, resolves itself into metallic mercury and oxygen gas. It may be similarly obtained from red oxide and peroxide of lead, the resulting products in these cases being protoxide of lead and oxygen. The following are the chief methods now employed: (1.) The black oxide (or binoxide) of manganese (MnO_2) is much employed as a source of this gas. The mineral is reduced to small pieces of about the size of a pea, and introduced into an iron bottle, with a pipe through which the gas may escape. When the bottle is placed in a furnace, and attains a red heat, the mineral parts with one-third of its oxygen and the red oxide of manganese (MnO, Mn_2O_3) remains behind; the reaction being explained by the equation:

(2.) A very pure and abundant supply of oxygen may be obtained by heating chlorate of potash (KO, ClO_3), which yields up all its oxygen (amounting to 39.16 per cent.), and leaves a residue of chloride of potassium. One ounce of this salt yields nearly two gallons of oxygen gas.

It is found by experiment, that if the chloride of potash is mixed with about a fourth of its weight of black oxide of copper, or binoxide of manganese, the evolution of the gas is greatly facilitated, although the oxides do not seem to undergo any change during the process. (3.) Oxygen is readily obtained by heating strong sulphuric acid with about half its weight of powdered black oxide of manganese, or chlorate of potash, in a glass retort; the reaction in the former case being expressed by the equation:

and in the latter case, being of a more complicated character. (4.) Various processes have been proposed for obtaining the gas on a large scale, of which the following, recommended by St. Claire Deville and Debray, is perhaps the best: The vapor of hydrated sulphuric acid is passed over red-hot platinum, by which it is decomposed into oxygen and sulphurous acid, the latter of which may easily be separated (and made available for the formation of sulphites) by its solubility in water or alkaline solutions. It has been calculated that a cubic metre (35.375 cubic feet) of oxygen costs 8s. 4d. when obtained from chlorate of potash; nearly 4s. 1d. when obtained from manganese; and only 10d. when obtained from sulphuric acid.

Of the compounds of oxygen, it is unnecessary to speak here, as they are described in the article on the other chemical elements. Oxygen was discovered almost simultaneously, in the year 1774, by Priestley and by Scheele, the English chemist having the prece-

dence by a few weeks. Priestley gave it the name of *Dephlogisticated Air*; Scheele termed it *Empyreal Air*; Condorcet shortly afterwards suggested *Vital Air*, as its most appropriate designation; and in 1789, Lavoisier, who, by a series of carefully conducted and very ingenious experiments, proved that the combustion of bodies in the air consisted essentially in their chemical combination with oxygen, and thus overthrew the *Phlogiston* (q. v.) theory, gave it the name which it now retains in consequence of his (erroneously) believing that it possessed a certain property which is described in the article OXYACIDS.

OXYHY'DROGEN MICROSCOPE. See SOLAR MICROSCOPE.

OXYRHYNCHUS, the name of a celebrated Egyptian fish, said to be revered throughout Egypt, and sacred to the goddess Athor. Its name in Egyptian is *kha*, and the fish in the hieroglyphs was used for this syllable, and particularly expressed the idea of the body. In the ritual, the deceased particularly stated that he had not caught this fish. The name appears to have comprised the genus *Mormorus*, distinguished by its pointed nose and long dorsal fin. The fish was worshiped in one of the nomes, which was called after it, and the inhabitants held it in such reverence that they would not touch any fish captured by a hook. When the portions of the body of Osiris were flung into the Nile, this fish alone ate one portion of his body. The *O.* was not eaten in Egypt, except by the natives of the Cynopolites Nomos. Its modern names is *Mizeleh*, which seems retained in the Coptic Penge, the name of the city of Oxyrhynchus. It is represented both in the sculptures and on the coins of the Nome, and was anciently embalmed. The city of Oxyrhynchus is the modern Behneseh, lying on the west bank of the Nile, in Lower Egypt, near the Bahr-el-Jusuf.

OXYU'RIS VERMICULARIS is the name now assigned by most zoologists to the intestinal worm described as *Ascaris* (q. v.) *vermicularis*, yet it is the original and true *Ascaris*. For the mode of recognizing the presence of this worm, and treating patients suffering from its presence, the reader is referred to the articles VERMIFUGES and WORMS.

O'YER and TE'RMINER Fr. *ouir*, to hear; *terminer*, to determine. A commission of oyer and terminer is granted by the crown to the judges and others to hear and determine all treasons, felonies, and trespasses; and it is by virtue of this commission that the judges on circuit dispose of criminal cases in the various circuits. Sometimes a special commission of the same kind is issued, authorizing the judges to go and try prisoners at other than the ordinary times.

O'YSTER (*Ostrea*), a genus of lamellibranchiate molluscs, of the section with a single adductor muscle. See LAMELLIBRANCHIATA. The shell consists of two unequal and somewhat irregularly shaped valves, of laminated and coarsely foliated structure; and the hinge is without tooth or ridge, the valves being held together by a ligament lodged in a little cavity in each. The animal is, in its organization, among the lowest and simplest of lamellibranchiate molluscs. It has no foot; and, except when very young, no power of locomotion, or organ of any kind adapted to that purpose. Its food consists of animalcules, and also of minute vegetable particles, brought to it by the water, a continual current of which is directed towards the mouth by the action of the gills. The gills are seen in four rows when the valves of the shell are separated, a little within the fringed edge of the mantle. In the most central part is the adductor muscle; towards the hinge is the liver, which is large; and between the adductor muscle and the liver is the heart, which may be recognized by the brown color of its auricle.

The mouth—for, as in the other lamellibranchiata, there is no head—is situated beneath a kind of hood, formed by the union of the two edges of the mantle near the Linge. It is jawless and toothless. The ovaries are very large during the season of reproduction, which extends over certain months in summer, when oysters are out of season for the table. Oysters are hermaphrodite. They produce vast numbers of young. Leeuwenhoek calculated that from 3000 to 4000 exist within an *O.* at once when 'sick,' 'milky' or full of spawn; and according to Poli, one *O.* produces about 1,200,000 eggs. The eggs are hatched within the shell and mantle of the parent, and the young are to be seen swimming slowly in a whitish and mucous or creamy fluid surrounding the gills, which becomes darker and of a muddy appearance when they are about to be expelled. Each young *O.* is then about 1/16th of an inch in length, and about two millions are capable of being closely packed in the space of a cubic inch. When the parent *O.* expels the young, and this is done simultaneously by multitudes on an oyster-bank, the water becomes filled with a thick cloud, and the spawn—called *spat* by fishermen—is wafted away by currents; the greater part, of course, to be generally lost, by being driven to unsuitable situations, as exposed rocks, muddy ground, or sand to which it cannot adhere, or to be devoured by fishes and other marine animals, but some to find an

object to which it can attach itself for life. The young come forth furnished with a temporary organ for swimming, ciliated, and provided with powerful muscles for extending it beyond the valves and withdrawing it at pleasure; and when the O. has become fixed in its permanent place of abode, this organ, being no longer of any use, has been supposed to drop off, or gradually to dwindle away and disappear.

Frank Buckland some years ago expressed the opinion, that the swimming organ of the young oyster was in the 'lungs,' and remains as the 'lungs' in the mature oyster. The four figures given represent the young oyster much magnified. Figs. 1, 3, 4

Fig. 1.

Fig. 2.

are views of the upper and under side; fig. 2 is an edge view. In very favorable situations, oysters grow rapidly, so that the Common O. is ready for the table in a year and a half or two years;

Fig. 3.

Fig. 4.

but in other places, a longer time is required, often about five years.

The species of O. are numerous, and are found in the seas of all warm and temperate climates. None have been found in the coldest parts of the world. The COMMON O. (*O. edulis*) is the only British species. Like it, the other species are generally found where the water is of no great depth; and some of them, also like it, are very abundant in estuaries, where the water is not very salt. The mangrove swamps of warm climates often abound in oysters of excellent flavor (*O. parasitica*, &c.) adhering to the roots and branches of the trees, within the reach of the tide. Some of the species differ from the Common O. not a little in form, as the LONG-HINGED O. (*O. Canadensis*) of North America, which is very elongated; and some of them far exceed it in size. Sir J. E. Tennent states that he measured the shell of an edible O. in Ceylon, and found it a little more than 11 inches in length by half as many in breadth; 'thus unexpectedly attesting the correctness of one of the stories related by the historians of Alexander's expedition, that in India they had found oysters a foot long.' Some species of O. have the valves plaited with strong longitudinal plaits.—For the illustrations here given, we are indebted to the kindness of the editor of the *Field*.

Young oysters readily attach themselves to the shells of old ones, and thus, in favorable circumstances, oyster-banks increase rapidly, so as to fill up shallow parts of the sea, and to form walls which effectually resist the waves and tide. This is very remarkably the case on the alluvial shores of Georgia and some other parts of North America, where these banks are called *Raccoon Banks*, because the racoon, among other animals, visit them to feed upon the oysters. Marshy land extends inwards from 12 to 18 miles from the sea, with tidal rivers meandering through it, and these rivers are kept pretty constant to their channels by the walls of living oysters on both sides. Large bunches of oysters may even be found among the long grass. It is not unusual for the inhabitants of the neighborhood to light a fire and roast a bunch of oysters on the spot. So abundant are the oysters in many places, that a vessel of 100 tons might be loaded within three times her own length. American oysters, which are of excellent flavor, have of late been imported (alive) into Britain to the value of £100,000 a year.

Notwithstanding the prodigious fecundity of the O., however,

the beds or banks which yield it for the markets of Britain and other European countries are not sufficiently productive to satisfy the demand, and it is not so much an article of ordinary food for all classes, as a luxury of the wealthy.

The usual mode of taking oysters by dredging is destructive, although, for oyster-beds, which are at all states of the tide covered with a considerable depth of water, nothing better has been devised, and the anxiety of fishermen to make the most of the present opportunity has caused many beds to be almost ruined by over-dredging. But the artificial formation of oyster-beds has been resorted to with great promise of success. It is indeed no novelty, having been practiced by the Romans. Pliny says that 'the first person who formed artificial oyster-beds was Sergius Orata, who established them at Baia. . . . This was done by him, not for the gratification of gluttony, but for the sake of gain, as he contrived to make a large income by the exercise of his ingenuity.' Sergius Orata lived in the time of Augustus. Among the *vicaria* of later emperors and other wealthy Romans were *ostreaaria*, specially devoted to oysters; and oyster-culture has never ceased to be practised in Italy, although to an inconsiderable extent, and particularly in Lake Fusaro, the Acheron of Virgil, a muddy saltwater pond, nowhere more than two yards deep. In Britain, it has also long been practised to some extent, particularly on the coasts of Kent and Essex, for the supply of the London market.

In 1864, an act of parliament was passed, giving exclusive rights to a Company, called the 'Herne Bay, Hampton, and Reculver Oyster Fishing Company,' over a certain portion of the shore at Herne Bay, extending about six miles in length by $1\frac{1}{2}$ in breadth. The oyster-beds fished by the public had, till then, yielded a very small supply; and it was urged that this supply could be largely increased by a well-managed Company. In order that the public should not be injured by this legislation, it was declared by one of the clauses of the Act that 'If the Company fail to maintain and cultivate the beds, or to produce well-fed oysters fit for the public market in such quantities as to be of public advantage, all the privileges conferred on the Company would be withdrawn, and the dredging of the beds, as formerly, thrown open to the public to fish.'

In 1869, the Board of Trade commissioned Mr. Pinwell, Inspector of Oyster Fisheries, to visit the oyster-culture grounds of France, in order to ascertain whether we could gather any useful hints therefrom. In his Report he explained that the English plan, as conducted at Herne Bay, Reculver, Whitstable, Langston Harbor, the Isle of Wight, and other localities, depends on the provision of salt-water tanks or ponds, in which the oysters are kept for a certain time. In France, the system is much more elaborate. He found that the coast is parted off into divisions or districts, each of which is placed under a maritime prefect. Each district is divided and subdivided into smaller portions, managed by commissioners, inspectors, syndics, and watchmen. The determination of 'close-time,' when oyster-fishing is totally prohibited; the decision how much to fish up, and how much to reserve for re-stocking; the discrimination between public oyster-beds and those which are made over to individuals by 'concessions;' the control of the fore-shore; the maintenance of oyster-breeding farms; the prevention of poaching by fishers not belonging to the respective districts—occupy quite an army of officials. Mr Pinwell recommended the adoption of some matters of detail from the French system, but not an imitation of the elaborate official machinery.

In 1872, the enhanced price of oysters in France attracted much public attention. Close observers arrived at an opinion that it was due to three causes—the impoverishment of some of the beds by injudicious dredging; a greatly increased demand for the supply of Germany and Russia; and a private understanding between many of the French Companies, leading to something very like a monopoly. The price per 100 was 1-20 francs in 1840, 2-83 francs in 1856, 4-58 francs in 1860, 7-20 francs in 1868, and no less than 11-20 francs in 1872. For consumption and further development, about 380,000,000 oysters were taken in 1881 from the basin of Arcachon, where the government has preserved banks, and the beds of Marennes and Concarneau; while, in 1880, from twenty-one places where this industry is carried on, about 195,000,000 were sent to market.

In 1874 the free fishers and the public of Herne Bay complained that the oyster company in that locality had not fulfilled the required conditions, while the company declared they had kept their agreement. The Board of Trade arranged a compromise, by which a certain portion of the ground was re-transferred to the public or free fishers; the remainder being left in the possession of the company, who would hold the exclusive right of fishing thereon, so long as they maintained the beds.—It is gratifying to find that oyster-culture is receiving much attention in Australia. Oyster-farms were established both in New South Wales and in Victoria in 1872.

Oysters live equally well in situations where they are constantly

under water, and in those which are left dry by the retiring tide. In 1882, a discovery was made of 10,000 acres of oyster-beds in the North Sea, 20 fathoms deep, and extending over a length of 200 miles, and a breadth of 60 or 70—unhappily not easily dredged. Where ebb-tide leaves them dry, they instinctively keep their valves closed when the water deserts them. It is in such situations that oyster-culture can be most easily and profitably carried on. Our space will not admit of details, which we would gladly give.

Various methods are adopted of preparing the artificial oyster-bed, by providing suitable solid objects for the oysters to attach themselves to. Stones are piled together, and in such a way that there are many open spaces among them; stakes are driven into the mud or sand; bundles of small sticks are fastened to stones or stakes; floors of planks are formed, at a little height above the bottom, with alleys between them, the under surface of the planks being roughened by the adze; and tiles are arranged in various ways, so as to turn to account the whole space at the disposal of the oyster-cultivator as high as the ordinary tides reach. The method must be varied in accordance with the situation, and the probable violence of winds and waves; but sheltered situations are best in all respects; and experience in France seems to prove that tiles covered with cement are preferable to everything that has yet been tried, as convenient for the cultivator, presenting a surface to which oysters readily attach themselves, and from which they can easily be removed, whilst the larger seaweeds do not grow on it so readily as on stones or wood. By the use of tiles covered with cement, the cultivator is also able easily to remove young oysters from breeding-grounds to feeding-grounds; the best breeding-grounds being by no means those in which the oyster most rapidly attains its greatest size, and that greenish tinge which Parisian epicures so much desire to see, and which is owing to the abundant confervæ and green monads of quiet muddy waters.—It has been long known that the oysters of particular localities are finer than those produced elsewhere. Nowhere, perhaps, are finer oysters produced than on some parts of the British coasts. Those of Rutupicæ, now Richborough, in Kent, were highly esteemed by the Romans, whose epicurism in oysters exceeded that of modern nations.

Of the culinary uses of oysters, it is unnecessary to say anything. Raw oysters, however, are generally believed to be more nutritious and more easily digested, as to many they are more delicious, than oysters cooked in any way; and it does not appear that any such evil consequences ever ensue from eating them, as are known to ensue from eating other kinds of uncooked food. Probably no parasite capable of developing into any form injurious to the human being exists in the oyster.

The genus *Ostrea* gives its name in some zoological systems to a family *Ostreædæ*. The fossil species are more numerous than the recent.

The name *O.* is popularly extended to many molluscs not included among the *Ostreædæ*, as the Pearl-oyster (*q. v.*).

Oysters raised in artificial beds are called 'natives,' and are considered very superior to those which are dredged from the natural beds; although to these last the name of 'native' would seem more appropriate than to the other. Some years ago, it was estimated that 500,000,000 oysters were consumed annually in London alone, at a cost of £100,000; but the supply has since lessened, and the price per 100 greatly increased. A large trade in oysters has sprung up in the United States; that of New York alone being estimated at \$25,000,000 annually.

Fossil Oysters.—A single species occurs in the Carboniferous Limestone, and as we rise in the crust of the earth, the genus becomes more and more common, no less than 200 species having been recorded, many of them scarcely distinguishable from the living species. The sub-genus *Gryphæa* was a free shell, with a large thick left valve and small concave right valve. Thirty species have been found in beds of the Oolite and Chalk periods. In the same beds there occurs another form of *Ostrea* with sub-spiral reversed umbones, to which the subgeneric name *Exogyra* has been given. Forty species of this form have been described.

OYSTERS, LAW AS TO. The rule is, that he who has the right of property in the soil or seashore, is entitled to catch or keep and breed oysters there. But the shore below the medium line of the tides belongs to the crown, and not to any individual; and it is only by virtue of some grant from the crown that an individual or a corporation can establish an exclusive title to the sea-shore, and in such a case is exclusively entitled to any oyster-beds there. It is thus always by virtue of a grant from the crown that oyster-fisheries are claimed as the property of an individual or of a corporation. The act 31 and 32 Vict. c. 45, however, now enables the Board of Trade to grant parts of the sea-shore of Great Britain to individuals for breeding oysters and mussels, and has given new remedies for the protection of this property. The general law is as follows: Whoever steals oysters or oyster-brood from an oyster-bed which is private property, is guilty of felony; and whoever unlawfully or wilfully uses any dredge, net, or in-

strument within the limits of a private oyster-bed, for the purpose of taking oysters, though none are actually taken, is guilty of a misdemeanor, and is liable to be imprisoned for three months. But persons are not prevented from fishing for floating fish within the limits of an oyster-fishery, if they use nets adapted for 'floating fish. Certain statutes as old as the time of Richard II. were passed to protect oyster-brood, but these were recently repealed by the Sea Fisheries Act, 1868 (*Paterson's Fishery Laws of the United Kingdom*). Under the convention between England and France, confirmed by the statute 31 and 32 Vict. c. 45, a close season is prescribed for oyster-fishing in the seas between England and France, from 15th June to 1st September, during which time oyster fishing-boats may be boarded by officers of the coast-guard or navy; and oysters illegally caught may be seized and destroyed, and the master is liable to a penalty.

In 1877, An act was passed appointing 15th June to 4th August as a close time for fishing deep-sea oysters, and from 14th May to 4th August for other kinds, in the British seas; it also grants power to prohibit the fishing in any locality for not more than a year. The law as to oysters in Scotland is substantially the same as in England. As to Ireland, the Irish Fishery Acts give power to the Irish Fishery Inspectors to grant a license to individuals, as is now done in England, to appropriate a certain tract of the shore for the purpose of forming oyster-beds, and thereupon the beds become private property (*Paterson's Fishery Laws*, p. 257). There is also a close season in Ireland for oysters, like what is established under the convention with France.

OYSTER BAY, a favorite watering-place on the north coast of Long Island, New York, U. S., on a deep sheltered bay, opening into Long Island Sound, 25 miles north-east of New York city. It abounds in handsome residences and fine scenery, and offers facilities for fishing, bathing, &c. Pop. (1870) 10,595; (1880) 11,923.

OYSTER-CATCHER (*Hematopus*), a genus of birds of the family *Charadriadæ* (*q. v.*), chiefly inhabiting sea-coasts, where they feed on molluscs, crustaceans, annelids, and other marine animals—sometimes even on small fishes. Their legs are of mod-

Oyster-catcher (*Hematopus ostralegus*).

erate length, like those of the plovers, and, like them, they have no hind-toe. The most remarkable generic distinction is found in the bill, which is long, strong, straight, much compressed and wedge-like towards the point. They are generally said to make use of the bill for opening the shells of oysters and other molluscs; but the late Mr. James Wilson expresses a very reasonable doubt on this point. The habits of the British species (*H. ostralegus*), so far as they have been accurately observed, agree with those of the American. It is only the European species, and is common on all parts of the British coasts, and on those of continental Europe, the north of Africa, and of the north of Asia. Its whole length is about 16 inches. Its finely-contrasted black and white colors have gained it the name of SEA PIE. It is most abundant on the sea-coast, but often visits inland regions and sometimes breeds in them. It does not make a nest, but lays its eggs—usually four—on the shingly beach or bare ground. On some of the sandy flat coasts of Lincolnshire, the *O.* is so abundant, that a bushel of eggs have been collected in a morning by a single fisherman. The American *O.* is a bird of passage, deserting the northern regions in winter. It is rather larger than the European species, and differs from it in colors, and in greater length and slenderness of bill.

OZÆ'NA (from the Gr. *ozo*, I smell), signifies a discharge of foetid, purulent, or sanious matter from the nostrils. It is a symptom rather than a disease, and may arise from ulceration of the membrane lining the nostrils, or from caries of the adjacent bones, and may accompany syphilitic, scorbutic, scrofulous, or cancerous affections of these or adjacent parts. A slighter form of ozæna sometimes follows chronic coryza (or cold in the head).

malignant scarlatina, and erysipelas of the face. The discharge is seldom accompanied by acute pain, unless when caused by cancer; sometimes, however, an aching is complained of. The prognosis must depend upon the nature of the disease, of which the discharge is a symptom. The treatment may be divided into the general or constitutional, and the local. The *general treatment* should consist of tonics combined with alteratives, as the preparations of bark with the alkalies, or with the mineral acids; a dry, bracing air, or a temporary removal to the seaside, is also usually of service. If the discharge arises from syphilis or scurvy, the treatment suitable to those diseases should be prescribed. The *local treatment* consists in the inhalation, once or twice a day, of the steam of boiling water, to which a little creosote or carbolic acid has been added; and in more severe cases, in the thorough syringing of the nostrils, so as to wash away all collections of matter with a copious stream of warm water, to which a little chloride of zinc has been added (about 30 minims of Burnett's solution to half a pint of water).

OZIE'RI, a town of the island of Sardinia, in the province of Sassari, 26 miles east-south-east from Sassari, amongst the mountains which occupy the center of the island. It stands in a deep valley, open only to the north, and is therefore peculiarly exposed to cold winds. Pop. (1871) 7965.

O'ZONE (Gr. *ozo*, I smell). It was remarked long ago that a peculiar odor was produced by the working of an electrical machine. Van-Marum found that, when electric sparks were passed through a tube containing oxygen, the gas became powerfully impregnated with this odor—which he therefore called the 'smell of electricity.' Subsequent writers attributed the phenomenon to the formation of nitric acid, due to a trace of nitrogen mixed with the oxygen; especially as the gas was found to act energetically upon mercury. Thus supposed to be explained, these curious results were soon forgotten. But in 1840, Schönbein (q. v.) with remarkable acuteness, made a closer investigation of the question, and arrived at many most curious results, all of which have not even yet been satisfactorily accounted for. The problem remains, in fact, one of the most perplexing, as well as interesting, questions imperfectly resolved in chemistry.

The earlier results of Schönbein were as follow: (1.) When water is decomposed by the voltaic current, the electrodes being of gold or platinum, the oxygen (which appears at the positive pole) possesses in a high degree the smell and the oxidizing power developed by Van-Marum by means of friction-electricity. (2.) When the positive electrode is formed of an oxidizable metal, these results are not observed, but the electrode is rapidly oxidized. (3.) The oxygen collected at a platinum electrode retains these properties for an indefinite period, if kept in a closed vessel; but loses them by heating, by the contact of an oxidizable substance, and even by contact with such bodies as charcoal and oxide of manganese. To the substance, whatever it may be, which possesses such powerful chemical affinities, Schönbein gave the name ozone, from its peculiar smell.

In 1845, he showed that the same substance can be produced by the action of phosphorus on moist air; and suggested that it might be a higher oxide of hydrogen.

De la Rive and Marignac shortly afterwards repeating the experiments of Van-Marum, showed that electric sparks produce ozone even in *pure and dry oxygen*; and came to the conclusion, that ozone is oxygen in an *allotropic* state, as diamond is a form of coke or charcoal.

Baumert, in 1853, endeavored to show that there are two kinds of ozone—one formed by pure oxygen by electric sparks, which

he allowed to be allotropic oxygen; the other formed in the voltaic decomposition of water, which he endeavored to prove to be a *teroxide* of hydrogen (HO_3). But Andrews, in 1856, completely refuted this view, by showing that no such oxide of hydrogen (at least in a gaseous form) is produced in the electrolysis of water; and that ozone, from whatever source obtained, is the same body; and is not a compound, but an allotropic form of oxygen.

In 1860, Andrews and Tait published the results of a series of *volumetric* experiments on this subject, which led to some remarkable conclusions—among which are the following: When the electric discharge is passed through pure oxygen, it *contracts*. If ozone be oxygen in an allotropic form, it must therefore be denser than oxygen. It was found also that a much greater amount of contraction, and a correspondingly greater quantity of ozone, were produced by a silent discharge of electricity between fine points, than by a brilliant series of sparks. The contraction due to the formation of the ozone is entirely removed by the destruction of the ozone by heat; and this process can be repeated indefinitely on the same portion of oxygen.

In attempting to determine the density of ozone, they used various bodies to take up the ozone from the oxygen containing it; and met with many very curious results. Thus, if mercury be introduced, it is immediately attacked and oxidized, and yet the oxygen *increases* in volume. If iodine be employed, it is immediately oxidized, and *no change* of volume was observed, though the apparatus would have at once rendered visible a change to the amount of $\frac{1}{1000}$ th of the bulk of the oxygen. By measuring the contraction produced by electricity in the oxygen, then the effect of introducing a solution of iodide of potassium, and determining the amount of oxygen taken up from the quantity of iodine set free, Andrews and Tait showed that the density of ozone, if it be allotropic oxygen, must be practically *infinite*—i. e., that ozone must have the density of a *liquid* or a *solid* at least, although existing in the gaseous form. This conclusion is, they say, inevitable, unless we make the very improbable assumption, that when iodine, &c., are exposed to ozone, one portion of the ozone (of volume, as oxygen, equal to the volume of the whole ozone) combines with the iodine, and the other portion is restored to the form of oxygen. The paper from whose statements we have quoted concludes with the suggestion that it is *possible* that in the formation of the ozone, oxygen may be decomposed. This is, of course, contrary to all the received notions of chemistry—but such a supposition would at once reconcile all the apparently contradictory facts connected with this singular body.

Soret and Von Babo have recently repeated and verified a few of these results, and the former, by using turpentine as an absorbing substance, and also by measuring its diffusion rate, has endeavored to show that the density of ozone is 50 per cent. greater than that of oxygen—a result on the whole consistent with the recent experiments of Brodie. Andrews has lately shown that ozone is rapidly destroyed when shaken up with dry fragments of glass, &c. He has also proved that the effect which is (almost invariably, and sometimes in fine weather powerfully) produced by the air on what are called ozone-test papers—papers steeped in iodide of potassium (and generally spoiled by the addition of starch) which are rendered brown (or blue) by the liberation of iodine—is really due to ozone. He did so by showing that it acts upon mercury as ozone does, and that it is destroyed by heat at the same temperature. *Nature* reported in 1880 that ozone had been liquefied, as the so-called permanent gases had been a year or two before; other experiments seem to prove that it is explosive.

P.

THE sixteenth letter of the English alphabet, was in Hebrew called *Pe*, i. e., mouth, most probably from its original form. P is the thin letter of the labial series (*p, b, f, v*), and is interchangeable with the other letters of the series. P, in Sanscrit, Greek, and Latin, is replaced by *f* in the Teutonic tongues. See F. Words beginning with *p* in English, and its kindred Teutonic tongues, are almost all of foreign origin (Slavic, Celtic, Latin), as *pain* (Fr. *peine*, Lat. *pena*), *plough* (Pol. *plug*), *pit* (Lat. *puteus*, a well). The Greek prep. *apo* (Saus. *apa*) became in Lat. *ab*; Gr. *hupo*, Lat. *sub*; Saus. *upa*, Lat. *ob*; but before sharp letters, as

t and *s*, the original *p* was retained in pronunciation, as is shown by inscriptions (*apstulit, optinui*). There are remarkable interchanges of *p* with the sharp guttural *k* or *q*. Thus, for Lat. *quis, quod, quam*, the Oscan dialect has *pis, pod, pam*; Lat. *equus, coquo*, corresponded to Gr. *hippos* (Æol. *hikkos*), *pepo*; similarly, Gaelic *mac* (son), *ceathair* (Lat. *quatuor*, four), *coig* (Lat. *quinque*, five), correspond to Welsh *map, pedwar* (Gr. *pettores*), *pump* (Gr. *pente* or *pemppe*). In Gr., *p* is sometimes replaced by *t*, as *tis, tessares* for *pis, pettores*. In such words as *redemption, consumption*, *p* has been introduced as an intermediary between the incompatible sounds *m* and *t*. The initial *p* of Latin words has for the most part passed into French unaltered;

in other positions, *p* has become *v*; thus, Fr. *évêque*, *cheveu*, *découvrir*, *pauvre*, from Lat. *episcopus*, *capillus*, *decipere*, *paupe*.

PA'CA (*Coelogenys*), a genus of rodent quadrupeds, allied to the agoutis, cavies, and capybara, and inhabiting Brazil, Guiana, and some of the West India Islands. The dentition very nearly resembles that of the agoutis. The cheek-bones are prodigiously developed, in a way of which no example exists in any other mammalian animal, so that the zygomatic arches enclose a large hollow space, whilst the bone also descends to an unusual depth from the arch, even below the lower jaw-bone. Within this structure, which gives an extraordinary breadth and peculiar aspect to the face, is a sac in each cheek, opening in front, and lined with a fold of the face. The whole of this seems to be intended to preserve the true cheek-pouches from external shocks. The cheek-pouches open from the mouth in the usual way, and are capable of very great distention. The lip is cloven; the ears are small; the eyes are large and full; the neck is short; the tail is a mere tubercle; the feet have each five toes; the legs are thick; the back is rounded. The form and gait are clumsy, yet the *P. (C. paca)* is very quick and active. It lives in moist grounds burrowing like a rabbit, but not so deeply; its burrow, however, is always provided with three openings. It feeds on vegetable substances, and often does great damage to plantations of sugarcane. It is one of the largest rodents, being about two feet long. It is generally of a dark-brown color, with four rows of white spots along the sides, the throat and belly white. A lighter colored species has been described, but is perhaps a mere variety. The flesh of the *P.* is much esteemed and is very fat.

PACAY (*Prosopis dulcis*), a tree of the natural order *Leguminosæ*, sub-order *Mimosæ*; a native of Peru, of rather large size, with a broad head; producing pods from twenty inches to two feet long, which contain black seeds imbedded in a sweet flaky substance as white as snow. This flaky substance is used as an article of food and much relished by the Peruvians,

PACE (Lat. *passus*), in its modern acceptation, is the distance, when the legs are extended in walking, between the heel of one foot and that of the other. Among disciplined men the pace becomes of constant length, and as such is of the utmost value in determining military movements, the relative distances of corps and men being fixed by the number of paces marched, and so on. The pace in the British army is $2\frac{1}{2}$ feet for ordinary marching, and 3 feet for 'double-quick' or running time.—With the Romans, the pace had a different signification, and it is important to bear the distinction in mind, when reading of distances in Latin works; the single extension of the legs was not with them a pace, (*passus*), but a step (*gradus*); their pace (*passus*) being the interval between the mark of a heel and the next mark of the same heel, or a double step. This pace was equivalent to 4·84 English feet. The pace was the Roman unit in itinerary measure; the mile being 1000 paces, or 5000 feet equal to '917 of an English Mile. See **MILE**. Whether measurements were effected by actually counting the paces, or by the time occupied, is not clear; but either method would, with disciplined troops, give a safe result.

In the middle ages, writers confuse accounts of distances by allusion to a geometrical pace, a measure which varied with different authors.

PACHO'MIUS, an Egyptian monk of the 4th c., is held in high estimation by the Roman Catholic church, as being the first to substitute for the free asceticism of the solitary recluse, a regular cenobitic system. He was born towards the close of the 3d c., was brought up as a pagan, but converted to Christianity by the kindness of certain Christians whom he encountered at Thebes. About 340 A.D., at Tabenna, an island in the Nile, he founded the first monastic institution. The members agreed to follow certain rules of life and conduct drawn up by P., and to subject themselves to his control and visitation. He also established the first convent for nuns, which was under the presidency of his sister, and labored with so much diligence and zeal, that at his death, according to Palladius, not fewer than 7000 monks and nuns were under his inspection. The various writings extant under the name of P. are—*Regula Monastica* (of doubtful genuineness), *Monita*, SS. PP. Pachomii et Theodori, *Epistolæ et Verba Mystica* (a farrago of unintelligible allegory), and *Præcepta S. Pachonii*.

PACHYDE'RMATA (Gr. thick-skins), in the system of Cuvier, an order of Mammalia, including part of the *Bruta* (Rhinoceros, Elephant), and all the *Belluæ* (Horse, Hippopotamus, Tapir, Hog, &c.) of Linnæus, besides one genus (*Hyrax* or *Daman*) of the Linnæan *Glires*. But subsequent investigation has demonstrated so close an alliance to be unnatural, and probably no Cuvierian order has been so thoroughly broken up. The elephants and hyrax now form two small independent orders—*Proboscidea* and *Hyrcoidæ*. The pigs and hippopotami form the non-ruminant division of the ungulate sub-order—*Artiodactyla* (q. v.), while the closely-

allied tapir, rhinoceros, and horse represent the perissodactyle ungulates. As defined by Cuvier, the order consists of those hoofed mammalia (*Ungulata*) which are not ruminants; all of which possess, as a more positive character, a remarkable thickness of skin. This order he divides into three sections—(1.) *Proboscidea*, having a prolonged snout or proboscis, through which the nostrils pass as elongated tubes, a powerful organ of prehension, and a delicate organ of touch, and having also five toes on each foot, enclosed in a very firm horny skin; (2.) *Ordinaria*, destitute of proboscis, although in some (Tapirs), there is such an elongation of the upper lip and nostrils as approximates to it; and the nose is employed by hogs, &c., in seeking their food, not only as an organ of smell, but as an instrument for turning up the ground, and as an organ of touch; the number of toes varies, four, three, or two on each foot; those with an even number of toes, having in the cleft foot a resemblance to the *Ruminantia*; and (3.) *Solidungula*, in which the foot has but one apparent toe, enclosed in a hoof. Some naturalists have thought it better to separate the *Solidungula* or *Epuidæ* (q. v.) from the *P.*, as a distinct order; whilst others have enlarged instead of restricting the limits of the order, by adding, as a fourth section, *Herbivorous Cetacea*, now known as *Sirenia*.

Those *P.* which have a number of toes differ completely from the mammalia having claws (*Unguiculata*) in their inability to bend their toes in order to seize any object. Some of the *Edentata* have very large hoof-like claws, but this difference still subsists. The fore-limbs of the *P.* are also incapable of any rotatory motion, serving for support and locomotion only, not at all for prehension; the metatarsal and metacarpal bones being consolidated as in the *Ruminantia*, and they have no clavicles.

The largest terrestrial mammalia belong to this order. Most of the *P.* are of large size, although the damans are a remarkable exception, and some of the hog family are also comparatively small. Most of them have a clumsy form, with a slow and awkward gait; but they are capable of activity beyond what might be supposed, and sometimes move at a pretty rapid pace. Gracefulness and fleetness are characteristics of the otherwise exceptional *Solidungula*. The *P. Ordinaria* have generally great strength, and the larger ones push their way through the entangled thickets of tropical forests, bending or breaking the lianas, small trees, and branches which oppose their progress, their thick hides resisting the spines and broken branches by which the skins of other animals would be pierced. The horse and other *Solidungula* are not inhabitants of forests and jungles, but generally of grassy plains, and their hides are much less thick and hard than those of most of the *Pachydermata*.

The physiognomy of the *P.* in general is rather dull and unexpressive, the eyes being small, and having that character of which a familiar example is found in the common hog. When enraged, however, they manifest their fierceness in their eyes; and although, in general, mild and gentle, they are capable of being aroused to great fury.

The skeleton of the *P. Ordinaria* and *Proboscidea* is strong and massive; the neck short, the processes of its vertebrae strongly developed; the skull affording a large surface for the muscles, which support and move it.

The *P.* generally feed on vegetable substances. Some are omnivorous. The digestive organs are more simple than in the *Ruminantia*, but exhibit considerable diversity. The stomach is simple in some, and in others is more or less completely divided into sacs, approaching to one of the most remarkable characters of the *Ruminantia*. The intestines are generally longer than in the *Ruminantia*. The dentition exhibits considerable diversity; the adaptation to vegetable food being the most prevalent character. The most important peculiarities of the dentition and digestive organs are noticed in the articles on particular families and genera.

PACIFIC OCEAN, the largest of the five great Oceans (see **OCEAN**), lies between America on the east, and Asia, Malaisia, and Australasia on the west. The name 'Pacific,' given to it by Magellan, the first European navigator who traversed its wide expanse, is doubtless very appropriate to certain portions of this ocean; but, as a whole, its special claims to the epithet are at the least doubtful, though the name has by long usage become too well established to be easily supplanted by any other.

The greatest length of the *P. O.* from the Arctic (at Behring's Strait) to the Antarctic circles is 9200 miles, and its greatest breadth, along the parallel of latitude 5° N., about 10,800 miles; while its area may be roughly estimated at 80,000,000 English square miles, or about $\frac{2}{3}$ ths of the whole surface of the earth. Its form is rhomboidal, with one corner incomplete (at the south), and its surface is studded with numberless islands, either scattered or in groups; these, however, are chiefly confined to the western side. Along the whole eastern side, there is a belt of sea of varying width, which, with a very few exceptions, is wholly free from islands. The deepest sounding yet found (in N. lat. 11° 24',

E. long. $143^{\circ} 16'$) in the P. O. is 26,850 feet, or above 5 miles—nearly equal to the height of the highest mountain on the globe.

The coasts of the P. O. present a general resemblance to those of the Atlantic, and the similarity in the outline of the western coasts of each is even striking, especially north of the equator; but the shores of the former, unlike those of the latter, are sinuous, and, excepting the north-east coast of Asia, little indented with inlets. The shore on the American side is bold and rocky, while that of Asia varies much in character.

Though the P. O. is by far the largest of the five great oceans, being about equal to the other four in extent, the proportion of land drained into it is comparatively insignificant. Its basin includes only the narrow strip of the American continent to the west of the Andes and Rocky mountains; Melanesia (with the exception of almost the whole of Australia), which contains few rivers, and none of them of large size; the Indo-Chinese states, China proper, with the east part of Mongolia, and Manchuria in the Asiatic continent.

Winds.—The trade winds of the Pacific have certain peculiarities, which have only lately been discovered. In general, they are not found to preserve their peculiar characteristics except within certain limits, thus, the south-east trades are found to blow steadily only between 92° and 140° of west longitude; while the north-east trades are similarly fluctuating, except between long. 115° W. and 214° W. Beyond these limits, their action is in whole or in part neutralized by the monsoons and other periodical winds peculiar to the tropical regions of the Pacific.

In Polynesia, especially near the new Hebrides group, hurricanes are of frequent occurrence from November to April, but they exhibit few of the terrible characteristics which distinguish the hurricanes of the West Indies and Indian Ocean. North and south of the tropical zone, the winds exhibit little periodicity, being found to blow from all parts of the compass at any given season of the year, though a general westerly direction is most frequent among them. On the coast of Patagonia and at Cape Horn, west winds prevail during the greater part of the year, while in the Sea of Okhotsk they are of rare occurrence. The frightful Typhoon (q. v.) is the terror of mariners in the Chinese seas, and may occur at all seasons of the year. There are many other winds and storms, such as white squalls, cyclones, 'tempestades,' &c., which are confined to particular localities, and will be found noticed under other heads, and also under STORMS.

Currents.—The currents of the P. O., though less marked in character and effects than those of the Atlantic, are yet of sufficient importance to require a brief notice. The *Southern Pacific current* takes its rise south of Van Dieman's Land, and flows eastward at the rate of half a mile per hour, dividing into two branches about long. 98° W., the northern branch or *Current of Mentor* turning northward, and gradually losing itself in the counter equatorial current; the southern branch continuing its eastward course till it is subdivided by the opposition of Cape Horn into two branches, one of which, the *cold Current of Peru* or *Humboldt's current*, advances northward along the west coast of South America, becoming finally absorbed in the equatorial current; the other washing the coast of Brazil, and becoming an Atlantic current.

The P. O., like the Atlantic, also possesses its equatorial current, separated into a northern and southern current by the equatorial counter-current. It sweeps across the whole ocean from east to west. Two subdivisions of the southern current, called respectively the 'current of Rossel' and the 'warm current of Australia,' flow, the one through the Polynesian Archipelago to New Guinea and the other along the east coast of Australia. The northern equatorial current, after reaching the coast of Asia, turns north-east, washing the shores of China and Japan, under the name of the *Black or Japan current*; it then sends off a branch along the coast of Kamtschatka, and advances eastward till it becomes lost on the north-west coast of North America. There are other minor currents, the most remarkable of which is that of Fleuriot, which describes a kind of irregular circle with a radius of about 240 miles. It is situated in lat. 25° — 40° N., and long. 138° — 155° W. All these currents have their corresponding counter-currents.

There are two 'sargassos' or weedy seas of considerable extent in the P. O., one lying 15° east-south-east of New Zealand; the other, and by far the larger, about 15° west of San Francisco in California. There is also a large region lying nearly half-way between Cape Horn and New Zealand, which seems to correspond to the deserts on land, as mariners report it almost wholly destitute of any signs of life either in sea or air.

History.—The existence of this ocean first became known to Europeans through Columbus, who had received accounts of it from some of the natives of America, though it was first seen by Balboa, September 29, 1513, and first traversed by Magellan eight years afterwards; but its size, limits, and the number and position of its islands, &c., were little known till long afterwards. Captain Cook deserves the first place among the investigators of the

P. O.; and after him come Anson, the two Bougainvilles, La Perouse, Carteret, Vancouver, Kruzenstern, Kotzebue, &c. But the most thoroughly scientific examination of its physical condition is that accomplished by the *Challenger Expedition* of 1873-76.

PACINIAN CORPUSCLES are very remarkable structures appended to the nerves. In the human subject, they are found in great numbers in connection with the nerves of the hand and foot, and sparingly on other spinal nerves, and on the plexuses of the sympathetic, but never on nerves of motion. They always present a *proximal end*, attached to the nerves by a stalk of fibrous tissue prolonged from the neurilemma, and occasionally one-tenth of an inch long; and a *distal end*, lying free in the connective or areolar tissue. In the human subject, the corpuscles vary in length from one-twentieth to one-tenth of an inch. They are usually seen very readily in the mesentery of the cat, appearing as pellucid oval grains, rather smaller than hemp-seed.

The microscopic examination of these bodies discloses an internal structure of a very remarkable kind. They consist, first, of a series of membranous capsules, from thirty to sixty or more in number, enclosed one within the other; and secondly, of a single nervous fibre, of the tubular kind, enclosed in the stalk, and advancing to the central capsule, which it traverses from beginning to end, and where it finally terminates in a fixed swollen extremity. The ten or fifteen innermost capsules are in contact with one another, while the rest are separated by a clear space containing fluid, which is so abundant as to constitute far the largest portion of the bulk of the entire corpuscle. Such are the views of Pacini (as given in the *Nuovi Organi Scoperte nel Corpo Umano*, 1840), who is usually regarded as their discoverer, although they had been noticed and roughly described nearly a century before by Vater, of Henle, and of Todd and Bowman; but later observations made by Huxley, Leydig, Kölliker, and others, show that the question of their true nature is still an open one. Huxley asserts that their central portion is solid, and not hollow; that in birds, and in the human hand, there is no fluid between the laminae—and indeed, that the laminae themselves have no real existence—the Pacinian corpuscle being merely a solid mass of connective tissue (a thickened process of the neurilemma of the nerve to which it is attached), whose *apparent lamination* depends on the regular disposition of its elastic elements. For a full description of the present state of knowledge as to the structure and function of these remarkable nerve-endings, see Quain's *Anatomy*, vol. ii.; *Histology*, by E. A. Schafer.

PACKFONG, or PETONG, a Chinese alloy or white metal, consisting of arsenic and copper. It is formed by putting two parts of arsenic in a crucible with five parts of copper turnings, or finely divided copper; the arsenic and copper require to be placed in alternate layers, and the whole is covered with a layer of common salt, and pressed down. When melted, the alloy contains nearly the whole of the arsenic, and is yellowish-white in color when in the rough state, but takes a fine white polish resembling silver. It is not very ductile, and cannot be fused without decomposition, as the arsenic is easily dissipated. It was formerly much used in this country, as well as China and India, for making the pans of small scales, dial-plates, and a variety of other articles requiring nicety of make, such as graduated scales for philosophical instruments. It is probably never imported now, the nickel alloys of Europe having quite superseded its use; in China, however, it is still extensively employed.

PA'CKHORSE, a horse employed in the carriage of goods, which are either fastened on its back in bundles, or, if weighty,

Packhorse and Panniers.

are placed in panniers, slung one on each side across the horse's back. The saddle to which the bundles were fastened consisted of two pieces of wood, curved so as to fit the horse's back, and joined together at the ends by other two straight pieces. This frame was well padded underneath, to prevent injury to the horse's back, and was firmly fastened by a girth. To each side of the saddle, a strong hook was attached, for the purpose of car-

ying packages, panniers, &c. Panniers were sometimes simply hung across the horse's back with a pad under the band. The panniers were wicker baskets, and of various shapes, according to the nature of their usual contents, being sometimes long and narrow, but most generally having a length of three feet or upwards, a depth of about two-thirds of the length, and a width of from one to two feet (see fig.). The packhorse with panniers was at one time in general use for carrying merchandise, and for those agricultural operations for which the horse and cart are now employed; and in the mountainous regions of Spain and Austria, and in other parts of the world, it still forms the sole medium for transport; though the mule has, especially in Europe, been substituted for the horse.

An army requires to be accompanied by several thousand pack-animals, sometimes horses, but preferably mules; and in Asia, commonly camels, or even elephants. Pack-saddles are variously fitted, according to the objects to be carried: some for provisions or ammunition; others for carrying wounded men, tents, and, in mountain-warfare, even small cannon. In battle, the immediate reserves of small-arm ammunition are borne in the rear of divisions by pack-animals; the heavy reserves being in wagons between the army and its base of operations.

PACOURY-UVA, a sweet and delicious Brazilian fruit, a large berry, produced by the *Platonia insignis*, a tree of the natural order *Oliviaceae*. The seeds have the taste of almonds.

PACTO'LUS, anciently the name of a small brook of Lydia, in Asia Minor, which rises on the northern slope of Mount Tmolus (modern *Buz Dagli*), flows north past Sardis (*Sart*), and empties itself into the Hermus (*Kodus*). It is never more than ten feet broad, and one foot deep. The sands or mud of P. were long famous in antiquity for the particles of gold dust which they contained, and which are supposed to have been carried down by its waters from the bosom of Tmolus—a hill rich in metals. The collection of these particles, according to legend, was the source of Cræsus's vast wealth. But as early even as the time of Strabo, P. had ceased to yield any of the precious dust. The brook is now called *Sarabat*.

PA'CTUM ILLI'CITUM is, in the law of Scotland, a contract or agreement for some illegal purpose, i. e., a purpose either expressly prohibited by statute, or by the general policy of the law. Thus, an immoral contract between a man and woman would be held void on the ground, that the law discountsenances practices *contra bonos mores*. A contract between a client and agent, called a *pactum de quota litis*, whereby a share of the property which is the subject of litigation is given to the agent instead of his usual fees, is void in most cases; though it is often difficult to determine what contracts fall within this rule. The courts, however, have construed very jealously every contract which tends to corrupt the administration of the law, and hence an agreement between a town and country agent to divide the profits has been held a *pactum illicitum*. So agreements by a client to give an excessive sum to his law-agent as a gift have been often set aside.—In England, similar doctrines prevail, though the phrase *pactum illicitum*, which was borrowed from the Roman law, is not used, contracts of this description being technically described as illegal contracts.

PADANG, the capital of the Dutch government of the west coast of Sumatra, is situated in 0° 59' 30" S. lat., and 100° 20' 30" E. long., and has about 12,000 inhabitants. The Padang flows through the town, but is only navigable for small vessels, the larger requiring to anchor in the roadstead, about three miles distant. On the left bank, stand the houses of the natives, unsightly bamboo erections, elevated about eight feet from the ground by posts of the cocoa-nut tree, and covered with leaves. The government buildings, houses of the Europeans and Chinese, &c., are on the right, and mostly built of wood or stone, and roofed with tile. P. is picturesquely enclosed by a semicircle of mountains, behind which rises a loftier chain, two being volcanoes. There are a Protestant church, a Roman Catholic church, flourishing schools, a fort, military hospital, government workshops, large warehouses, &c. An agent of the Netherlands Trading Company (q. v.) resides at Padang. Being the center of the exports and imports of Sumatra's west coast, P. has a lively trade, not only with Java, the other islands of the Eastern Archipelago and Europe, but also with the interior of the island.

The climate is considered healthy, although the heat is great. Colonel Nahuys found the thermometer range from 70° to 80° at 6 A.M., from 82° to 88° at noon, 84° to 90° at 2 P.M., 78° to 84° at 6 P.M., and from 72° to 80° at 10 in the evening.

The governor resides at a country-house about two and a half miles above P., and rules over a territory stretching from the Residency of Bencoolen (which has a population of 112,000 souls, and stands immediately under the government at Batavia), north-west over seven degrees of latitude. It is divided into the residencies of Lower Padang, Upper Padang, and Tapanoei

(Tapanuli); the population in 1870 being 1,600,730 natives, 2178 Europeans, and nearly 3000 Chinese.

Lower Padang was the first district of the west coast of Sumatra which submitted to the Dutch, who had formed a settlement at Padang as early as 1660, and by repeated wars, gradually extended their territory.

Upper Padang lies to the north-west of the lower province, from which it is separated by a chain of lofty mountains, some of which, as the Singalang, Merapie, and Sago, attain to nearly 10,000 feet in height; Merapie being an active volcano, the last eruptions of which were in 1845 and 1855, though it sent forth volumes of smoke in 1861. This residency possesses the most lovely districts of the island, or of any tropic land, the mountain slopes being studded with villages, rice-fields, cocoa-nut and coffee trees, of which last, it is calculated that there are 32,000,000 in Upper Padang. In addition to the coffee-culture, gambier, cassia, pepper, ratan, indigo, caoutchouc, &c., are largely produced, and gold, iron, copper, lead, and quicksilver are found. In the district of Tanah Datar is the town of Paggeroejong, formerly the capital of the powerful kingdom of Menangkabo, and the residence of the king.

Tapanoei, the remaining residency under the government of Sumatra's west coast, lies north-west from Upper Padang. The independent spirit of the inland natives has caused the Netherlands much trouble, but each fresh outbreak only extends their territory and power further into the interior, and towards the north-west of the island.

PADDLE, probably the precursor of the OAR (q. v.), and still its substitute among barbarous nations, is a wooden implement consisting of a wide flat blade with a short handle, by means of which the operator spoons the water towards him. In canoes for only one sitter, a double paddle is generally used, which is dipped alternately on either side: the inhabitants of Greenland are especially skilful in this operation. The action of the paddle is the same as that of the oar. The paddle has however, one advantage—viz., that the rower faces the bow of his boat, and therefore sees what is before him. In threading narrow streams, &c. this is an appreciable gain.

PADDLE-WHEEL—one of the appliances in steam-vessels by which the power of the engine is made to act upon the water and produce locomotion—is a skeleton wheel of iron, on the outer portion of whose radii flat boards, called floats or paddles, are fixed, which beat upon the water, and produce, continuously, the same effect as is given, in an intermittent manner, by the blades of oars. The use of paddle-wheels in conjunction with steam as a motive-power dates from about the commencement of the present century, but the employment of the paddle-wheel itself is as ancient as the time of the Egyptians. A specimen is also known to have been tried in Spain in the 16th century.

The fig. shows the usual form of paddle-wheel, that called the radial, in which the floats are fixed. It will be seen that a certain loss of power is involved, as the full force of the engine on the water is only experienced when the float is vertical, and as on entering and leaving the water the power is mainly employed in depressing or lifting the particles of water. This objection has

Paddle. Double Paddle.

Ordinary Paddle-wheel.

great force at the moment of starting, or when progress is very slow, as is illustrated by the small power a paddle-steamer evinces when trying to tug a stranded vessel off a sandbank; but when in full progress, the action is less impeded by this circumstance, the water in front of the wheel being depressed, and that abaft being thrown into the form of a wave. The extent of the immersion much influences the economy of power, as will be readily

understood if the consequences of immersion up to the center of the wheel be imagined. An immersion somewhat over the top of the lowest float is about the most advantageous, and in order that the floats may be as nearly as possible vertical when they strike the water, it is advisable to give the wheel as large a diameter as possible, and to place the axis at the highest available point in the vessel.

To overcome the drawbacks to the radial wheel, Elijah Galloway patented, in 1829, the *Feathering Paddle-wheel*, in which the floats are mounted on axes, and are connected by rods with a common center, which revolves upon a pin placed eccentrically to the axis of the paddle-wheel. By this method, the floats are

Feathering Paddle-wheel.

kept, while immersed, at right angles to the surface of the water. So long as the water is smooth the gain is great, consequently feathered floats are much used in river-steamers; but for ocean-steamers the liability to derangement, perhaps at a critical period, is a great objection to their use.

The paddle-wheel, in revolving, imparts both a forward velocity to the vessel and a backward velocity to the water. The latter is called the *slip*, and sometimes bears a very large and wasteful proportion to the former. The absolute velocity of the paddle floats is equal to the sum of the slip and the forward motion of the ship, so that the wheel always revolves faster than the ship makes way.

PADDY, or **PADDIE**, the name commonly applied in India to rice in the husk. It is the Tamul and the Malay name. See **RICE**.

PADE'LLA (Ital. a frying-pan; plur. *padelle*), a shallow vessel of metal or earthenware used in illuminations. The illumination of St. Peter's at Rome, and other buildings in Italy, is effected by the tasteful arrangement of large numbers of these little pans, which are converted into lamps by partly filling them with tallow or other grease, and placing a wick in the center. This mode of illuminating was first adopted on a large scale in Great Britain on the occasion of the marriage of the Prince of Wales with the Princess Alexandra, when the inhabitants of Edinburgh produced by this means a most magnificent illumination of their city.

PA'DERBORN, the chief town of a district in the Prussian province of Westphalia, situated in 51° 43' N. lat. and 8° 45' E. long., in a pleasant and fruitful district, is built at the source of the Pader, which bursts forth from below the cathedral with sufficient force to drive mills within 20 paces of its point of exit. Pop. (1890) 14,689. P. has narrow dark old-fashioned streets, presenting no special attractions, although it has some interesting buildings, as, for instance, the fine old cathedral, completed in 1143, with its two magnificent façades, and containing the silver coffin in which are deposited the remains of St. Liborius. It is the seat of a bishop and chapter, and of an administrative court. The manufactures of P., which are not very considerable, include tobacco, starch, hats, and wax-cloths, and there are several breweries, distilleries, and sugar-refineries in the town, which carries on a considerable trade in cattle, corn, and oils. P. is one of the important stations on the Great Westphalia Railway.

P., which ranked till 1803 as a free imperial bishopric, owes its foundation to Charlemagne, who nominated the first bishop in 795. Several diets were held during the middle ages at P., which at that period ranked as one of the most flourishing of the Hanseatic Cities, while it was also numbered among the Free Imperial Cities. In 1604, it was forcibly deprived by the prince-bishop, Theodor of Fürstenburg, of many of the special rights and prerogatives which it had enjoyed since its foundation, and compelled to acknowledge the Roman Catholic as the predominant church, in the place of Protestantism, which had been established during the time of Luther. In 1803, P. was attached as an hereditary principality to Prussia, and after being for a time incor-

porated in the kingdom of Westphalia, was restored to Prussia in 1813, and incorporated in the Westphalian circle of Minden.

PA'DIHAM, a large chapelry and township, in the higher division of the hundred of Blackburn, seated on an eminence springing from the north bank of the Calder, and reached by the Rose Grove station of the Lancashire and Yorkshire Railway, and also by the Leeds and Liverpool Canal. It is about 9 miles north-east of Blackburn. The cotton trade employs a great proportion of the population—with Hapton (1881) 8983—but coal-mines and extensive quarries also add to industrial activity and the prosperity of P.; which has been greatly improved in appearance recently by several new streets.

PADILLA, JUAN DE, one of the most popular heroes in Spanish history, was a scion of a Toledan family, and was appointed by the Emperor Charles V. military commandant of Saragossa. While he was so employed, a formidable rebellion, caused by the excessive taxes which the emperor imposed on the Spaniards, to defray the cost of his various wars in Italy, Germany, and the Low Countries, broke out among the towns (*comunidades*) of Castile, and the rebels, who were known as *comuneros*, called upon P. to put himself at their head. The introduction of the religious element into the quarrel tended greatly to strengthen the insurgents, and for an instant P. was the ruler of Spain, and formed a new junta to carry on the government. He was successful in a number of enterprises undertaken against the royalist party; but on the 23d April 1521, was completely beaten by the royalists at Villalobos. This conflict decided the fate of the rebellion and of P. himself, who was taken prisoner, and next day beheaded.

His wife, **DONA MARIA DE PACHECO**, rallied the wrecks of the rebel army, and for a long time held Toledo against the royalist besieging army, and after its fall, retired to Portugal, where she died soon afterwards. With P. and his wife expired the last remnant of the ancient freedom of Spain. Numerous poems and dramas celebrate their deeds.

PADI'SHAH, in Turkish **PADISHAH** (Persian *padi*, protector or throne, *shah*, prince), one of the titles of the Sultan of the Ottoman Empire, and of the Shah of Persia. Formerly, this title was accorded only to the kings of France among European monarchs, the others being called *Kral*, king. It was subsequently allowed to the Emperor of Austria, and still later, by a special article in the treaty of Kutshuk-Kainardji (10th January 1775), to the autocrat of All the Russias. Of late it has been accorded to the monarchs of all the great European nations, and even to those of secondary states.

PADRO'N, a very ancient town of Spain, in the province of Coruña, 15 miles south-west of Santiago, on the Sar, a few miles from the coast. P. being the place at which the body of Santiago is said to have landed itself, was formerly an important place of pilgrimage. Pop. (1877) 8424.

PA'DUA (Ital. *Padova*), capital of the province of the same name in Northern Italy, stands on a beautiful plain on the Bacchiglione, 28 miles by railway west-south-west of Venice. It is surrounded by walls and ditches, and is fortified by bastions. Its houses are lofty, supported for the most part on long rows of arches, generally pointed; and most of its streets, especially in the older quarters, are narrow, dark, dirty, and ill-paved. There are, however, several handsome gates, as those of San Giovanni, Savonarolo, and Falconetto; a number of fine squares, of which the Prato della Valle is the largest and the finest, and is surrounded by a stream, and planted with trees; and several magnificent buildings. Of these, the Café Pedrocchi is esteemed the finest edifice of the kind in Italy.

Portions of a Roman edifice were discovered while the foundations of this building were being made, and the marbles found now adorn the pavements, &c., and the *salone*. The Palazzo della Municipalità, built 1172–1219, is the most peculiar and most national in the city. It is an immense building, forming one side of the market-place, rests wholly on arches, and is surrounded by a loggia (q. v.). Its east end is covered with shields and armorial bearings, and its roof is said to be the largest unsupported by pillars in the world. Its hall is 267½ feet long, and 89 feet wide, is covered with mystical and metaphorical paintings, and contains a monument of Livy, the Roman historian, and a bust of Belzoni, the traveler, both natives of this city. The other chief edifices are the cathedral, the church of Sant' Antonio, a beautiful building in the Pointed style, with several Byzantine features, and remarkably rich and splendid in its internal decorations; and the churches of San Giorgio and of Santa Giustina; all of them richly decorated with paintings, sculptures, &c. The university of P., the most famous establishment in the city, was celebrated as early as the year 1221. It embraces 61 professors and other teachers, and is attended by about 1000 students. Connected with the university are an anatomical theater and a botanic garden, both dating from the 16th c., and each the first of its kind in

Europe. There is also a museum of natural history, an observatory, a chemical laboratory, and a library of 120,000 volumes and 1500 manuscripts. There are also numerous palaces, theaters, and hospitals. Pop. (1881) 72,174.

P., the Roman *Patavium*, is one of the most ancient towns of Italy. According to a wide-spread belief of antiquity, alluded to by Virgil, it was founded by the Trojan chief Antenor, but we really know nothing of its history until it became a Roman town. During the first centuries of the empire, it was the most flourishing city in the north of Italy, on account of its great woollen manufactures, and could return to the census more persons wealthy enough to be ranked as *equites* than any other place except Rome. But in 452 Attila utterly razed it to the ground. It was, however, rebuilt by Narses, again destroyed by the Lombards, but once again rose from its ashes, and became a very famous city in the middle ages. It fell into the hands of the Carrara family in 1518, and in 1405 it was conquered by Venice, the fortunes of which it has since shared.

PADUCAH, a city of Kentucky, U. S., on the south bank of the Ohio River, just below the mouth of the Tennessee River, 322 miles below Louisville. It is the entrepôt of a fertile country, and has a large trade by the rivers, the Louisville, Paducah, and South-western, and the Paducah and Memphis Railways. It contains county buildings, 4 banks, 3 shipyards, steam saw-mills, extensive manufacturing establishments, and 15 churches. Pop. (1880) 8876.

PADULA, a town of South Italy, in the province of Salerno, 52 miles south-east of the town of Salerno, in a mountainous district. Below P. are the ruins of the once famous and magnificent monastery, *La Certosa di S. Lorenzo*, despoiled by the French during the occupation of Calabria. Pop. (1861) 8556.

PÆ'AN (of doubtful etymology), the name given by the ancient Greeks to a kind of lyric poetry originally connected with the worship of Apollo. The oldest pæans, as we learn from Homer, appear to have been either hymns, addressed to that deity for the purpose of appeasing his wrath (*Iliad*, i. 473), or thanksgiving odes, sung after danger was over and glory won (*Iliad*, xxiii. 391). Nevertheless, at a later period, they were addressed to other deities also. Thus, according to Xenophon, the Lacedæmonians sung a pæan to Poseidon after an earthquake, and the Greek army in Asia one to Zeus.

PÆDO-BAPTISM. See BAPTISM, INFANT.

PÆ'ONY (*Paonia*), a genus of plants of the natural order *Ranunculaceæ*; having large flowers, with five persistent, unequal, leafy, and somewhat leathery sepals, 5—10 petals, many stamens, and 2—5 germens, which are crowned with a fleshy recurved stigma. The leaves are compound, the leaflets often variously and irregularly divided. The fibres of the root are often thickened into tubers. The species are large herbaceous perennials, or rarely half-shrubby; natives of Europe, Asia, and the north-west of America. None of them are truly indigenous in Britain, although one (*P. corallina*) has found admittance into the English Flora. On account of the beauty of their flowers, some of them are much cultivated in gardens, particularly of the COMMON P. (*P. officinalis*), a native of the mountain-woods of the south of Europe, with carmine or blood-red flowers. A variety with double flowers is common.—The WHITE P. (*P. albiflora*) is another favorite species. It is a native of the central parts of Asia. Its flowers are fragrant.

The TREE P., CHINESE P., or MOUTAN (*P. Moutan*), is a half-shrubby plant, a native of China and Japan. In favorable circumstances, it attains a very large size, and a height of twelve feet or more. It has been long cultivated in China and Japan; and is now also a favorite ornamental plant in the south of Europe, and in the south of England and Ireland; but the late spring-frosts of most parts of Britain are injurious to it, although it can bear severe frost in winter, when vegetation is at a stand. It flowers in spring. The varieties in cultivation are numerous. It is propagated by cuttings, and also by grafting. Its germens are surrounded by a cup-shaped lacinated membrane.—The roots of most of the pæonies have a nauseous smell when fresh, and those of the common P. were in high repute among the ancients as an antispasmodic—hence the name Pæony, from *Paion*, a Greek name of Apollo, the god of medicine—but their medicinal properties are now utterly disregarded. The globose, shining black seeds of pæonies were formerly, in some countries, strung into necklaces, and hung around the necks of children, as *anodyne necklaces*, to facilitate dentition. The Daurians and Mongolians use the root of *P. albiflora* in their soups, and grind the seeds to mix with their tea.

PÆ'STUM, anciently a Greek city of Lucania, in Southern Italy, in the present province of Salerno on the *Sinus Pasturnus*, now the Gulf of Salerno, and not far from Mount Alburnus. It was founded by the Troezenians and the Sybarites, some time between 650 and 610 B.C., and was originally called Poseidonia (of

which *Pæstum* is believed to be a Latin corruption), in honor of Poseidon (Neptune). It was subdued by the Samnites of Lucania, and slowly declined in prosperity after it fell into the hands of the Romans, who established a colony here about 273 B.C. The Latin poets celebrate the beauty and fragrance of its flowers, and particularly of its roses, which bloomed twice a year. Wild roses, it is said, still grow among its ruins, which retain their ancient property, and flower regularly both in May and November. P. was burned by the Saracens in the 10th c., and there is now only a small village called Pesto, in a marshy, unhealthy, and desolate district; but the ancient greatness of the city is indicated by the ruins of temples and other buildings. These appear to have been first noticed in the early part of the 18th c., by a certain Count Gazola, in the service of the king of Naples; they were next described by Antonini, in the work on the topography of Lucania (1745), and have since been visited by travelers from all parts of Europe.

PAGA'NI, an uninteresting town of South Italy, province of Salerno. In the church of St. Michele is the tomb of Alfonso de' Liguori, founder of the order of the Redemptionists, who died here, 1787. The body is preserved in a glass case. Pop. about 12,000.

PAGANINI, NICOLÒ, a famous violinist, son of a commission-broker at Genoa, where he was born in 1784. His musical talent showed itself in his childhood; in his ninth year, he had instructions from Costa at Genoa, and afterwards from Rolla at Parma, and from Ghiretti. In 1801, he began his professional tours in Italy; in 1828, he created a great sensation on appearing for the first time in the principal towns of Germany; and in 1831, his violin-playing created an equal *furor* in Paris and London. His mastery over the violin has never been equalled, but he was too much addicted to using it in mere feats of musical legerdemain, such as his celebrated performance on a single string. His execution on the guitar was also very remarkable; for four years he made that instrument his constant study. P. died at Nice in 1840, leaving a large fortune.

PA'GANISM, another name for Heathenism or Polytheism. The word is derived from the Latin *paganus*, a designation of the inhabitants of the country (*pagus*), in contradistinction to the inhabitants of towns, the more educated and civilized inhabitants of towns having been the first generally to embrace Christianity, whilst the old polytheism lingered more in remote rural districts.

PAGE (derivation variously assigned to Gr. *pais*, a boy and Lat. *pagus*, a village), a youth employed in the service of a royal or noble personage. The practice of employing youths of noble birth in personal attendance on the sovereign, existed in early times among the Persians, and was revived in the middle ages under feudal and chivalric usages. The young nobleman passed in courts and castles through the degree of page, preparatory to being admitted to the further degrees of esquire and knight. The practice of educating the higher nobility as pages at court, began to decline after the 15th c., till pages became what they are now, mere relics of feudal usages. Four pages of honor, who are personal attendants of the sovereign, form part of the state of the British court. They receive a salary of £200 a year each, and on attaining a suitable age, receive from her Majesty a commission in the Foot Guards.

PAGET, FAMILY OF. This noble family, though said to be of Norman extraction, do not trace their descent further back than the reign of Henry VII., in whose time, one William P. held the office of one of the sergeants-at-mace of the city of London. His son William, who was educated at St. Paul's School, and at Cambridge, was introduced into public life by Stephen Gardiner, Bishop of Winchester, early in the reign of Henry VIII., who sent him abroad to obtain the opinions of foreign doctors as to his contemplated divorce from Catharine of Aragon. From this time forth his rise was rapid, and he was constantly employed in diplomatic missions until the death of the king, who appointed him one of his executors. He now adhered to the party of the Protector Somerset, and was raised to the peerage in 1552, as Lord Paget of Beaudesert. He shared in the power, and also in the fall of the Protector, and was heavily fined by the Star Chamber, who also deprived him of the insignia of the Order of the Garter. His disgrace, however, was not of long continuance, and a change taking place in the councils of his opponents, he soon obtained his pardon. On the accession of Queen Mary, he was sworn a member of the privy council, and obtained several large grants of lands. He retired from public life on the accession of Elizabeth, who regarded him with much favor, though he was a strict Roman Catholic. The representative of the family adhered to the cause of Mary Queen of Scots, and suffered, in consequence, the confiscation of his property.

The fifth Lord P. so far departed from the traditional policy of the family as to accept from the parliament the lord-lieutenancy of Buckinghamshire; but he returned to his allegiance

shortly afterwards, and held the command of a regiment under the royal standard at the battle of Edgehill. His grandson was advanced to the earldom of Uxbridge, but this title becoming extinct, the representation of the family devolved on a female, who carried the barony of Paget by marriage into the house of Bayly. The son of this marriage, however, having assumed the name of Paget, obtained a renewal of the earldom of Uxbridge, and the second earl, for his gallantry at Waterloo, was advanced to the marquessate of Anglesey. Of late years, the P. family have usually held three or four seats in every parliament, and they have constantly supported the liberal party.

PAGING-MACHINE. Several machines have been made for paging books and numbering banknotes, cheques, railway-tickets, and other similar papers. The great object of these machines is to prevent the chance of error or fraud by making it impossible that a page, cheque, &c. can be abstracted or lost without detection. Messrs. Waterlow and Sons of London perfected an ingenious machine, by which pages of books, such as ledgers and other commercial books, and banknotes, &c., are numbered in regular succession. The numbers are engraved on metal rows, usually of steel or brass. A series of these rows are so arranged, that when the machine is worked, the numbers must be impressed on the paper in regular succession from 1 to 99,999; and it is impossible to produce a duplicate number until the whole series has been printed. The instrument is made to supply ink to the types, so that it may be locked in such a manner as to admit of being worked without the chance of its being tampered with.

An extremely ingenious modification of this machine has been perfected by M. Auguste Trouillet of Paris, under the name of 'Numérateur Mécanique,' which is not only more simple, but admits of wider application; for it not only pages books and numbers notes, tickets, &c., but can also be used for numbering bales and other packages of merchandise. The instrument has six rows, on each of which is a set of engraved numbers, so arranged, that their revolutions produce in regular succession the required numbers, by the action of a lever which moves horizontally, and supplies the type with ink as it moves backwards and forwards.

PA'GO, an island belonging to the Austrian crownland of Dalmatia, separated from Croatia by the Morlaacca Canal, a channel from two to three miles in width. It is long and narrow, runs parallel to the Croatian coast, and has an area of 108 square miles. Pop. 5150, who are most industrious, and support themselves by vine-culture, the manufacture of salt and fishing.

PAGO'DA (according to some, a corruption of the Sanscrit word *bhagavata*, from *bhagavat*, sacred; but according to others, a corruption of *put-gada*, from the Persian *put*, idol, and *gada*, house) is the name of certain Hindu temples, which are amongst the most remarkable monuments of Hindu architecture. Though the word itself designates but the temple where the deity—especially S'iva, and his consort Durgā or Pārvatī—was worshiped, a pagoda is in reality an aggregate of various monuments, which, in their totality, constitute the holy place sacred to the god. Sanctuaries, porches, colonnades, gateways, walls, tanks, &c., are generally combined for this purpose, according to a plan, which is more or less uniform. Several series of walls form an enclosure; between them are alleys, habitations for the priests, &c., and the interior is occupied by the temple itself, with buildings for the pilgrims, tanks, porticoes, and open colonnades. The walls have, at their openings, *gopuras*, or large pyramidal gateways, higher than themselves, and so constructed that the gopura of the outer wall is always higher than that of the succeeding inner wall, the pagoda itself being smaller than the smallest gopura. The extent of the enclosing walls is generally considerable; in most instances, they consist of hewn stones of colossal dimensions, placed upon one another without mortar or cement, but with such admirable accuracy, that their joints are scarcely visible. The gateways are pyramidal buildings of the most elaborate workmanship; they consist of several, sometimes as many as fifteen stories.

The pagodas themselves, too, are of a pyramidal shape, various layers of stones having been piled upon one another in successive recession; in some pagodas, however, the pyramidal form begins only with the higher stories, the broad basis extending to about a third of the height of the whole building. The sides of the different terraces are vertical; but the transition from one to the other is effected by a vault surmounted by a series of small cupolas, which hide the vault itself. A single cupola, hewn out of the stone, and surmounted by a globe, generally crowns the whole structure; but sometimes the latter also ends in fantastical spires of a fanlike shape or concave roofs. The pagodas are covered all over with the richest ornamentation. The pilasters and columns, which take a prominent rank in the ornamental portion of these temples, show the greatest variety of forms; some pagodas are also overlaid with strips of copper, having the appearance of gold. The most celebrated pagodas on the mainland of India are those

of Mathura, Trichinopoli, Chalambron, Konjeveram, Jaggernaut, and Deogur, near Ellora.—That of Mathura consists of four stories, and is about 63 feet high; its base comprises about 40 square feet. Its first story is made of hewn stones, copper, and covered with gilt; the others with brick.

A great number of figures, especially representing deities, tigers, and elephants, cover the building.—The pagoda of Tanjore is the most beautiful monument of this kind in the south of India; its height is 200 feet, and the width of its basis is equal to two-thirds of its height.—The pagoda of Trichinopoli is erected on a hill, elevated about 800 feet over the plain; it differs in style from other pagodas dedicated to Brahminical worship, and exhibits great similarity with the Buddhistical monuments of Tibet.—The great pagoda of Chalambron, in Tanjore, is one of the most celebrated and one of the most sacred of India. It is dedicated to S'iva and Pārvatī, and filled with representations belonging to the mythical history of these gods. The buildings of which this pagoda is composed cover an oblong square, 860 feet long, and 210 feet wide.—At Konjeveram, there are two pagodas—the one dedicated to S'iva, and the other to Pārvatī.—The pagodas of Jaggernaut, on the north end of the coast of Coromandel, are three; they are erected likewise, in honor of S'iva, and are surrounded by a wall of black stones—whence they are called by Europeans the Black Pagodas—measuring 1122 feet in length, 696 feet in width, and 24 feet in height. The height of the principal of these three pagodas is said to be 344 feet; according to some, however, it does not exceed 120–123 feet.—The pagoda of Deogur, near Ellora, consists also of three pagodas, sacred to S'iva; they have no sculptures, however, except a trident, the weapon of S'iva, which is visible on the top of one of these temples.

The monuments of Mavalipura, on the coast of Coromandel, are generally called the Seven Pagodas; but as these monuments—which are rather a whole city than merely temples—are buildings cut out of the living rock, they belong more properly to the rock-cut monuments of India, than to the special class of Indian architecture comprised under the term pagoda.

The term pagoda is, in a loose way, also applied to those Chinese buildings of a tower-form, which consists of several stories, each story containing a single room, and being surrounded by a gallery covered with a protruding roof. These buildings, however, differ materially from the Hindu pagodas, not only so far as their style and exterior appearance are concerned, but inasmuch as they are buildings intended for other than religious purposes. The Chinese call them *Ta*, and they are generally erected in commemoration of a celebrated personage, or some remarkable event; and for this reason, too, on some elevated spot, where they may be conspicuous, and add to the charms of the scenery. Some of these buildings have a height of 160 feet; the finest known specimen of them is the famous Porcelain Tower of Nanking (q. v.). The application of the name pagoda to a Chinese temple should be discontinued, for, as a rule, a Chinese temple is an insignificant building, seldom more than two stories high, and built of wood; the exceptions are rare, and where they occur, as at Peking, such temples, however magnificent, have no architectural affinity with a Hindu pagoda.

Porcelain Tower of Nanking.

PAGU'RUS AND PAGU'RIDÆ. See HERMIT CRAB.

PAHLANPUR', a town of India, capital of the state of the same name, 260 miles east-south-east of Hyderabad. It is a walled town, is the seat of extensive trade and of several manufactures. Pop. estimated at 30,000, many of whom are artificers and shopkeepers. The state of which P. is capital lies between lat. 25° 57'–24° 41' N., and long. 71° 51'–72° 45' E. One-seventh of the population are Moslem, and the remainder Hindus. The state, whose revenue, 1870–1871, was £37,593, pays an annual tribute of £5000 to the Guicowar, and £600 per annum for the maintenance of a British political agent. The exact area of the state is not known; the state, however, contains 300 villages; pop. 216,000. The products are wheat, rice, sugar-cane, and cotton. In the north and west, the soil yields only one crop annually; but in the south and east, three crops are obtained in the year.

PAILA is, according to the Purāṇas (q. v.), one of the disciples of Vyāsa (q. v.), the reputed arranger of the Vedas (q. v.), he was taught by the latter the R'igveda, and, on his part, communicated this knowledge to Bāshkali and Indrapramati. This tradition, therefore, implies that P. was one of the earliest compilers of the R'igveda.

PAIN is an undefinable sensation, of the nature of which all persons are conscious. It resides exclusively in the nervous system, but may originate from various sources. Irritation, or excessive excitement of the nervous system, may produce it; it frequently precedes and accompanies inflammation; while it sometimes occurs in, and seems to be favored by, a state of positive depression, as is seen in the intense pain which is often experienced in a limb benumbed with cold, in the pain which not unfrequently accompanies palsy, and in the well known fact, that neuralgia is the common result of general debility. Hence, pain must on no account be regarded as a certain indication of inflammation, although it rarely happens that pain is not felt at some period or other in inflammatory diseases. Moreover, the pain that belongs to inflammation, differs very much, according to the organ or tissue affected; the pain, for example, in inflammation of the lungs, differs altogether in character from that which occurs in inflammation of the bowels, and both these pains from that occurring in inflammation of the kidneys.

Pain differs not only in its character, which may be dull, sharp, aching, tearing, gnawing, stabbing, &c., but in its mode of occurrence; for example, it may be flying or persistent, intermittent, remittent, or continued. It is not always that the pain is felt in the spot where the cause of it exists. Thus, inflammation of the liver or diaphragm may cause pain in the right shoulder, the irritation caused by stone in the bladder produces pain at the outlet of the urinary passage; disease of the hip-joint occasions pain in the knee, disease of the heart is often accompanied with pain in the left arm, and irritation of the stomach often gives rise to headache. Pain is differently felt by persons of different constitutions and temperaments, some persons being little sensitive to painful impressions of any kind, while others suffer greatly from slight causes. There even seems to be national differences in this respect; and before the introduction of chloroform, it was a matter of common observation that Irishmen were always more troublesome subjects for surgical operations than either Englishmen or Scotchmen; and the negro is probably less sensitive to pain than any of the white races.

Although in most cases we are to regard pain merely as a symptom to be removed only by means which remove the lesion which occasions it, there are cases in which, although it is only a symptom, it constitutes a chief element of disease, and one against which remedies must be specially directed. As examples of these cases, may be mentioned neuralgia, gastralgia, colic, dysmenorrhœa, and perforation of the intestines; and in a less degree, the stitch of pleurisy, which, if not relieved, impedes the respiration, and the pain of tenesmus, which often causes such efforts to empty the lower bowel, as seriously to disturb the functions of the intestine, and to exhaust the strength.

For the methods of relieving pain, the reader is referred to the articles on the different diseases in which it specially occurs (as COLIC, NEURALGIA, PLEURISY, &c.), and to those on CHLOROFORM, ETHER, INDIAN HEMP, MORPHIA, NARCOTICS, OPIUM, &c.

PAINE, THOMAS, an author famous for his connection with the American and French revolutions, and for his advocacy of infidel opinions, was born 29th January 1737, at Thetford, in the county of Norfolk, in England. He was trained to the business of his father, who was a staymaker, but afterwards obtained a situation in the Customs, and the management of a tobacco-manufactory. His income, however, was small, and he fell into debt, and was dismissed in 1774, upon which he went to America, was favorably received by a bookseller in Philadelphia, and in 1776 published a pamphlet entitled *Common Sense*, written in a popular style, in which he maintained the cause of the colonies against the mother-country.

The success and influence of this publication were extraordinary, and it won him the friendship of Washington, Franklin, and other distinguished American leaders. He was rewarded by Congress with the appointment of Secretary to the Committee of Foreign Affairs, visited France in the summer of 1787, where he made the acquaintance of Buffon, Malesherbes, La Rochefoucauld, and other eminent men; and in the autumn following, went to England, where in 1791, he published *The Rights of Man*, the most famous of all the replies to Burke's *Reflections upon the French Revolution*. The work has gone through innumerable editions, and has been translated into almost all the languages of Europe. His defence of the principles of the French Revolution against the magnificent assault of Burke and the outcry of the English aristocracy is vigorous, and by no means unsuccessful. But the value or at least the popularity of the work has been injured by its advocacy of extreme liberal opinions. His assaults on the British constitution exposed him to a government prosecution, and he fled to France, where he was admitted to citizenship; and in 1793, the department of Pas-de-Calais elected him a deputy to the National Convention, where he voted with the Girondists. At the trial of Louis XVI., says Madame de Staël, 'Thomas

Paine alone proposed what would have done honor to France if it had been accepted—the offer to the king of an asylum in America; by which he offended the Mountain party; and in 1793, Robespierre caused him to be ejected from the Convention, on the ground of his being a foreigner, and thrown into prison.

During his imprisonment, he wrote *The Age of Reason*, against Atheism, and against Christianity, and in favor of Deism. After an imprisonment of fourteen months, he was released, on the intercession of the American government, and restored to his seat in the Convention. He was chosen by Napoleon to introduce a popular form of government into Britain, after he should have invaded and conquered the island. But as Napoleon did not carry out his design, P. was deprived of an opportunity of playing the part of legislator for his conquered countrymen. He then retired into private life, and occupied himself with the study of finance. In 1802, he returned to the United States, and died there 8th June 1809. The most complete edition of his works is that by J. P. Mendum (Bost. 1856); the most noted of his numerous biographers is William Cobbett (1796).

PAINS AND PENALTIES. When a person has committed some crime of peculiar enormity, and for which no adequate punishment is provided by the ordinary law, the mode of proceeding is by introducing a bill of pains and penalties, the object of which, therefore, is to inflict a punishment of an extraordinary and anomalous kind. These bills are now seldom resorted to, and the last instance of an attempt to revive such a form of punishment was by the ministers of George IV. against Queen Caroline, an attempt which was signally defeated. When a bill of this kind is resolved upon, it is introduced, and passes through all the stages like any other bill in parliament, except that the party proceeded against is allowed to defend himself or herself by counsel and witnesses. The proceeding is substantially an indictment, though in form a bill.

PAINTER, in naval matters, is the rope by which a boat is fastened to a ship or pier.

PAINTERS' CREAM, a composition used by artists to cover oil-paintings in progress, when they leave off their work; it prevents drying, and the consequent showing of lines where new work is begun. It consists of six parts of fine nut oil, and one part of gum-mastic. The mastic is dissolved in the oil, and then is added a quarter part of acetate, or sugar of lead, finely triturated with a few drops of the oil. When well incorporated with the dissolved mastic, water must be added, and thoroughly mixed, until the whole has the consistency of cream. It is applied with a soft brush, and can easily be removed with water and a sponge.

PAINTING, the art of representing objects to the eye on a flat surface by means of lines and color, with a view to convey ideas and awaken emotions. See ART. As one of the fine arts, painting occupies a prominent place; some claim for it the first place, as combining the chief elements—namely, form, light and shade, and color. As compared, however, with music and poetry, it lacks the important element of movement, the representation being confined, in a great measure, to one aspect and one instant of time. In its ruder and more elementary forms, in which the primary design was to communicate ideas, painting is perhaps the oldest of the arts, older, at all events, than writing (see ALPHABET, HIEROGLYPHICS); and, as a vehicle of knowledge, it possesses this advantage over writing—that no description, however minute can convey so accurate and distinct an idea of an object as a pictorial representation, much less make so vivid an impression. Besides this, it is not limited, as writing is, by differences of language, but speaks alike to all nations and all ages.

The great antiquity of painting is proved by remains discovered in Egypt, and by reference to it in ancient writings. It has been ascertained that as early as the 19th c. B.C., the walls and temples of Thebes were decorated by painting and sculpture. Ezekiel, who prophesied about 598 years B.C., refers to paintings in Jerusalem after the manner of the Babylonians and Chaldeans. Though no specimens have come down to us, it is evident that paintings of the highest excellence were executed in Greece. This is proved by what is recorded of them, for the subjects of many of those mentioned required the putting forth in a high degree of all the qualities requisite for the production of the greatest historical works, such as form, grouping, expression, foreshortening. From the immense sums given for paintings, the care with which they were preserved in temples and other public buildings, and from the fact of the high state of sculpture of contemporary periods, as proved by well-known works now extant, it may be deduced that painting, which like sculpture, is based on design or drawing, must have occupied an equally high position. Even the imperfect specimens of painting discovered in Pompeii, where the style and influence of Greek art may be traced to some extent, lead to conclusions highly favorable to the high position of painting in classic times. The chief schools of painting in Greece were those of Sicyon, Corinth, Athens, and Rhodes. The first great artist of whose works there is any authentic description

and from details of which an idea may be formed of his attainments, is Polygnotus of Thasos (flor. 420 B.C.), who painted, among other works, those in the Peecile, a celebrated portico at Athens, and the Lesche, or public hall at Delphi.

The works of Apollodorus of Athens (flor. 408 B.C.) are described and highly praised by Pliny. Zeuxis, the pupil of Apollodorus, Eupompus, Androcles, Parrhasius (q. v.) the Ephesian, and Timanthes of Sicily, prosecuted painting with distinguished success, and by them it was carried down to the time of Philip the father of Alexander. Of the same period was Pamphilus, celebrated not only for his works, but as the master of the artist universally acknowledged as the greatest of the ancient painters, Apelles (q. v.), who was born probably at Colophon, and flourished in the latter half of the 4th c. B.C. He was highly esteemed by Alexander the Great, and executed many important works for that monarch. Protogenes of Rhodes was a contemporary, and may be styled the rival of Apelles, who greatly admired his works. His picture of Ialysus the hunter and the nymph Rhodos was preserved for many years in the Temple of Peace at Rome. Art in Greece had now reached its highest point; its course afterwards was downward.

In Italy, art was followed at a very early period by the Etruscans, and, according to Pliny, painting, as well as sculpture, was successfully practised in Ardea and Lanuvium, cities of Latium, perhaps more ancient than Rome. The finest specimens of Etruscan art, however—as the paintings on tombs, and the remains of armor and fettle were ornamented with figures, evince unmistakably the influence of, or rather are identical with Greek art. According to Pliny, it was introduced from Corinth about 650 B.C.

No great national school of painting ever flourished in Rome, for though the names of Romans who were painters are cited, the principal works of art that adorned the temples and palaces of Rome were obtained from Greece, and it is probable that many of the paintings executed there were by Greek artists. When the seat of empire was transferred to the East, such art as then remained was carried with it, and in a new phase was afterwards recognized as Byzantine art—a conventional style, in which certain typical forms were adopted and continually repeated. This mode has been preserved, and is practised in church-painting in Russia at this present time.

Much discussion has arisen in modern times as to the supposed technical modes or processes of painting employed by the ancients. It seems established that painting in fresco was much practised; but many of the most valuable pictures we read of were removable, and there are accounts of some carried from Greece to Rome. 'The Greeks preferred movable pictures, which could be taken away in case of fire' (*Wilkinson on Egyptian and Greek Paintings*), and Pliny says Apelles never painted on walls; besides fresco paintings on walls, therefore, there can be no doubt that the ancients painted on boards; indeed, the name *Tabula* or *Tabula picta* proves this, and it seems to be now generally acknowledged that these were executed in tempera—that is, with size, and probably fixed or protected by some kind of varnish, in the preparation of which oil was used; or in encaustic, a process in which wax was employed to fix and give brilliancy and depth to the colors, heat being applied in working with it.

Painting was revived in Europe in the 13th c.; previous to that period, Byzantine artists chiefly were employed. On the conquest of Constantinople by the Latins in 1204, the Byzantine school was broken up, and many Greek artists were transplanted to Italy, where art was now destined to flourish, so the works of the Italians who profited by their instructions, were necessarily, at the commencement, composed in the Byzantine style. The first Italian whose name is associated with the revival of Italian art is Guido di Siena; a work by him, a large Madonna, inscribed with his name and the date 1221, is still preserved in that city. The next is Giotto da Pisa (1236). But Giovanni Cimabue (q. v.) (1240—1300), is commonly styled the founder of the Italian school. Several works of considerable importance are ascribed to him; and though he followed the Byzantine arrangement, he ventured occasionally out of the path, introduced the study of nature in his drawing, and imparted a greater degree of softness to his painting than the Byzantine artists. The influence of Byzantine art was not confined to Italy; it operated in Germany, Bohemia, and France; but there also art began to assume a national character early in the 13th c., and paintings are still preserved at Cologne, dated 1224.

The Italian school of painting, or that style in which so many of the highest qualities of art have been so successfully carried out, received its chief impetus from Giotto (q. v.), the son of Bordone, born in 1276 at Vespignano, near Florence, where he died in 1336. It is said that he was originally a shepherd-boy, and being discovered by Cimabue drawing a sheep on a slate, was instructed by him in painting. His style is distinguished from that of earlier painters by the introduction of natural incidents and impressions, by greater richness and variety of composition, by the dramatic interest of his groups, and by total disregard of

the typical forms and conventional style of his predecessors. His influence was not confined to Florence, but extended over the whole of Italy; and works by this artist may be traced from Padua to Naples. Giotto followed Pope Clement V. to Avignon, and is said to have executed many important pictures there, and in other cities in France. The most celebrated of his frescoes now extant are those of Assisi; some noted works by him in that class also remain at Padua, Florence, and Naples. Most of the small easel-pictures ascribed to him are of doubtful authenticity, but some preserved in the gallery at Florence are acknowledged to be genuine. His high powers as a sculptor and architect are also exemplified by works in that city.

Giotto had numerous scholars and imitators, and several of these have left works which show that while they profited by his instruction or example, they were also gifted with original talent. Among these may be noticed Taddeo Gaddi, the favorite pupil of Giotto (born 1300, living in 1352); Simone Memmi (1284—1344); and Andrea Orcagna (1329—1389), one of the artists employed in the decoration of the celebrated Campo Santo at Pisa. Painting in Italy continued to be impressed with the feeling and style of Giotto for upwards of a hundred years; but early in the fifteenth century, the frescoes executed by Masaccio (1401—1443) in the Brancacci Chapel in the Carmelite Church at Florence, clearly prove that it had entered on a new phase, and had come forth strengthened by an important element in which it formerly was deficient, viz., correct delineation of form, guided by the study of nature. These celebrated frescoes, twelve in number, were at one time all ascribed to Masaccio; but it seems now to be acknowledged by judges of art that two of these are by Masolino da Panicale (1378—1415), the master of Masaccio; and three, or probably four, and a small portion of one, by Filippino Lippi (1460—1505). The frescoes by Masaccio, however, are superior to those by Masolino and Lippi, and, indeed, for many of the highest qualities in art, have, as compositions, only been surpassed by Raphael in his celebrated cartoons.

In about a century from Masaccio's time, painting in Italy attained its highest development; but before referring to those artists who are acknowledged as having carried painting to the highest elevation it has attained since the period of the middle ages, it is right to note the names of some of the painters who aided in raising it to that position. The works of Fra Giovanni da Fiesole (1387—1455) are highly valued and esteemed by many critics as the purest in point of style and feeling, and so the best fitted for devotional purposes. Confining his efforts to simple and graceful action, and sweet and tender expression, he adhered to the traditional types, and ventured on none of the bold innovations which were introduced in his time, and carried so far by Masaccio. His example, as regards feeling and expression, influenced many succeeding artists, particularly Pietro Perugino, the master of Raphael (1446—1524), and Francesco Francia of Bologna (1450 or 1453—1517), by both of whom these qualities, united to greatly improved technical power, were brought to high excellence. Giovanni Bellini, the founder of the early Venetian school (1422—1512), has left many admirable works; he had numerous scholars, among them Titian and Giorgione. Domenico Corradi or Ghirlandajo, under whom Michael Angelo studied, successfully followed out that direction given to art by Masaccio, which involved individuality of character and expression in the figures. Andrea Mantegna, of the school of Padua (1430—1506), along with strong expression, gave an impetus to form, modelled on Greek or classic art.

Luca Signorelli of Cortona (about 1440—1521), successfully exemplified powerful action and bold foreshortening, particularly in his frescoes at Orvieto, which, with his other works, are supposed to have strongly influenced the style of Michael Angelo. Antonello da Messina (1447—1496) is said to have been a pupil of Jan Van Eyck, who imparted to him his secret in the preparation and use of oil-colors, the knowledge of which he spread among the Venetians. The above statement, however, as to the exact period at which oil-painting was first introduced, is one attended with much doubt. Painting in colors mixed with oil is mentioned by Italian writers before the period of Van Eyck; painting in tempera, or size, was continued in Italy, particularly in the Florentine and Roman schools, to the time of Raphael; and the transition from the one method to the other has been so gradual, that many judges of art have expressed inability to determine whether the pictures of Perugino, Francia, and Raphael are in oil or tempera, or in both. The practice of painting on canvas, in place of wooden boards or panels, was introduced and carried on for a considerable time in Venice before it was adopted in other parts of Italy, and canvas is the material best suited for pictures in oil-colors, when they are not of small dimensions; so, on the whole, the conclusion seems to be, that though oil-painting was not unknown in Florence and the south of Italy, painting in tempera was longer practised there than in Venice.

At the time when the painters above referred to flourished, there were many able artists in Germany, whose works are deservedly

very highly prized. Among these, Jan Van Eyck (q. v.), (about 1390—1441), deserves special notice. To him is generally given the credit of being the first painter who used oil in place of size in his colors. His works are remarkable for brilliant and transparent coloring and high finish. He had numerous scholars; among these Justus of Ghent (flor. 1451), Hugo Vander Goes (died 1480)—supposed to be the painter of the celebrated wings of an altar-piece, now at Holyrood Palace, containing portraits of James III. and his queen—Roger of Bruges (1365—1418), Hans Hemling or Memling (died 1489), the best scholar of the Van Eyck school; Quintin Matsys (1450—1529), Jan Van Mabuse (1470—1532), Albert Dürer (q. v.), (1471—1528), Lucas Van Leyden (q. v.), (1494—1533). The career of the two last named extended to the best period of art, and for many high qualities their works strongly compete with those of the ablest of the Italians; while portraits by Hans Holbein (q. v.), (1497—1554), and Antonio More (1512—1588) rank with those of any school or period. The leading qualities in German art are invention, individuality of character, clearness of coloring, and high finish; but they are inferior to the Italians in embodying beauty; their representation of the nude is angular in form and deficient in the elegance and grace attained by the painters of Italy; and in their draperies they do not attain the simplicity and grandeur so remarkable in the works of their southern competitors.

Anything like an account of the artists by whom painting was carried to its highest pitch, of sufficient comprehensiveness to exhibit their peculiar æsthetic qualities, cannot be attempted in so short a notice as this; but that deficiency is in some degree supplied by, and reference is made to, the biographical notices of distinguished painters given in this work under their names. Keeping this reference in view, therefore, the next step is to note the relative positions generally assigned to the most distinguished painters of that period, with reference to the estimation in which their works are now held. Leonardo da Vinci (q. v.), (1452—1519), Michael Angelo Buonarroti (1474—1568), and Raphael or Raffaello Sanzio of Urbino (1483—1520), are universally acknowledged as the three greatest among the Italian artists; but two other names may be added as worthy to be put in an equally high place—those of Titian (q. v.), (1477—1576), and Antonio Allegri, surnamed Correggio (q. v.), (1494—1534). These five painters exhibit in their works, some of them the whole, others the greater portion of the various elements—which in the earlier periods of art had existed apart, and composed distinct styles—united, and more highly developed; while each of them has taken up one of these elements, and carried it not only further than his predecessors had done, but further than it was by his contemporaries, or by any subsequent artist. Thus we see in Leonardo's celebrated picture of the 'Last Supper,' that though he has adopted the traditional style of composition handed down from Giotto's time, and carried out the religious feeling and dignified expression aimed at by the older masters, the whole is deepened and elevated by the manner in which it is worked out—namely, by a mind and hand possessing mastery over all the elements that are combined in the production of the highest works of art.

Michael Angelo was a proficient in all the qualities that constitute a painter, but he carried several of them—viz., grandeur of design, anatomical knowledge, and power of drawing—far beyond all other artists of his own or of later times. Titian and Correggio, again, with great power over every art-element, have each carried one quality further than all other artists—the former, color; the latter, light and shade. Raphael is generally allowed the first place among painters, for, though each of the four artists just referred to carried one, or perhaps two, of the qualities of painting further than he did, he excelled them in every other element but the one for which each was particularly distinguished, and in several of the highest qualities of art he attained to greater excellence than any other artist; the expression of dignity of movement by broad masses and grand lines aimed at in the works of Masaccio, is successfully realized in the cartoons at Hampton Court; and the pictures in which Perugino and Francia so earnestly and successfully embodied female beauty, maternal affection, and infantine purity, are as much inferior to pictures of similar subjects by Raphael as they are above those executed during the decadence of Italian art. Besides the five leading masters just referred to, there were many other Italian artists of great talent, who may be ranged in three classes: 1, the contemporaries of those artists; 2, those influenced by their style; 3, their scholars. Among their contemporaries, the works of Fra Bartolommeo (1469—1517) and Andrea Vanucchi, called Andrea del Sarto (1488—1530), both Florentines, deservedly rank very high. Giorgio Barbarelli, called Giorgione (1478—1511), was, under Bellini, a fellow-pupil of, and is generally styled the rival of Titian; and his works, which are of great excellence, prove that he was worthy of that name.

In class 2, Correggio himself may rank as being influenced by Leonardo's style, but the great prominence of his other qualities makes his style original and independent. On Bernardino Luini

about (1460, living in 1530), Leonardo's influence is direct; and as he was an able painter, his pictures are very valuable for embodying many of those qualities in art which Leonardo had so much improved. Sebastino del Piombo, a Venetian (1485—1547), studied under Giovanni Bellini and Giorgione; and after settling in Rome, became intimate with Michael Angelo, who employed him to paint some of his designs, with a view of benefiting by his admirable coloring. His pictures are greatly esteemed, as uniting rich color to grandeur of design. Class 3. All the five leading artists above referred to had pupils or scholars, particularly such of them as, like Raphael, were much engaged in extensive works in fresco, in the execution of which assistants are generally employed. A complete list of these, however, would occupy too much space here. Among the scholars of Michael Angelo, Daniele da Volterra (1509—1566) was the best; and among Raphael's scholars, the first place is generally accorded to Giulio Pippi or Romano (q. v.), (1492—1546). After the first quarter of the 16th c., painting in Italy, except in the Venetian school, showed symptoms of rapid decline; that school, however, continued its vitality longer than any other in Italy, having flourished with all the life of originality during the whole 16th century. This is attested by the productions of many able Venetian painters; but among those, the works of Jacopo Robusti, or Tintoretto (q. v.), (1512—1594), and Paolo Caliari, or Veronese (q. v.) (1528—1588), are by far the most important. The pictures of the former exhibit great vigor in composition, and much richness of color—the former quality evincing the influence of Michael Angelo; the latter, that of Titian.

Veronese ranks before even Tintoretto: his compositions are animated and full, and as a colorist he is a powerful rival to Titian, not aiming at the rich glow of that master's tints, but excelling every artist in producing the brilliancy and sparkling effect of mid-daylight on figures gorgeously attired, and seen against backgrounds enriched with landscape and architecture. The other great schools of Italy, however, as already said, had less vitality than the Venetian, and showed symptoms of decay at the end of the first quarter of the 16th century. Raphael left numerous scholars and assistants; many of these, after his death in 1520, quitted Rome. The pillage of that city by the French under Bourbon in 1527 had also the effect of dispersing them, and this naturally led to the style of Raphael, so far as they could acquire it, being transplanted into other parts of Italy; but Raphael's style was founded on his own peculiar feeling for the beautiful, and on his own peculiar grace; and all that his scholars had acquired or could convey was a mere imitation of his external forms, without the spirit and pure feeling of which these forms are the expression. The imitation of Michael Angelo became the great object with the Florentines; but his scholars and imitators being unable to comprehend his powerful spirit, and not possessing his technical powers and theoretical knowledge, their pictures are merely exaggerated compositions of academic figures. Nor were Correggio's scholars more successful in following his walk, for they exaggerated the peculiarities of his style, which in their hands became affected and insipid. Leonardo's scholars repeated his distinguishing qualities, modified by their own individual peculiarities. (Ruskin made it his work to teach 'the supremacy of five great painters, Turner, Tintoret, Luini, Botticelli, and Carpaccio, despised till he spoke of them.')

The German painters who succeeded Dürer, Van Leyden, and the other celebrated artists of their period, before referred to, endeavored to improve their national style by the study of Italian art, at first attempting to combine the two styles, and afterwards, to the close of the 16th c., devoting themselves exclusively to the study or imitation of the Italian painters. The works of these artists, the worst productions of any school, form a connecting link between those of the famous old German masters and the vigorous, varied, and attractive works of the painters of the Netherlands in the 17th century.

Towards the end of the 16th, and during the first half of the 17th c., a revival of art in Italy was attempted. This was sought for in two ways by two classes of artists; the larger body were known by the name of Eclectics, from their having endeavored to select and unite the best qualities of each of the great masters, combined with the study of nature; the other class were distinguished by the name of Naturalists, and they aimed at forming an independent style, distinct from that of the earlier masters, based on the indiscriminate imitation of common life, treated in a bold and lively manner. In their development, both classes exercised an influence on each other, particularly the Naturalists on the Eclectics. Eclectic schools arose in various parts of Italy, but the most celebrated was that at Bologna, founded by Lodovico Carracci (q. v.), (1555—1619), assisted by his two nephews, Agostino Carracci (1558—1602), and Annibale Carracci (1560—1609) the most eminent of the three. Many painters of mark were reared in this school; among those, Domenico Zamperli, called Domenichino (q. v.), (1581—1641), and Guido Reni (q. v.), (1575—1642), were by far the most eminent.

The art of the Eclectics has been greatly overrated. Till recently the leaders of that school were always placed on an equality with the best masters of the early part of the 16th c., and far above any of the painters of the 15th century. These notions have recently undergone a complete change; it is now acknowledged that the attempt of the Eclectics to combine the excellences of various great masters, involves misapprehension with regard to the conception and practice of art, for the greatness of the earlier masters was brought out in their individual and peculiar qualities, the uniting of which implies a contradiction. Michael Angelo Amerighi da Caravaggio (q. v.), (1569—1609) was the founder of the Naturalist school; he resided principally at Rome, but at a later period went to Naples, Malta, and Sicily. The Naturalists were in their greatest strength in Naples, where they perseveringly opposed the followers of the Carracci, their leader being Giuseppe Ribera (q. v.), a Spaniard, hence called Spagnoletto (1593—1656). With much of the force of Caravaggio, he united more delicacy and greater vivacity of color. The historical or Scriptural subjects of Salvator Rosa (q. v.), (1615—1673) are in the style of the school of the Naturalists; but on account of his *genre* pieces and landscapes, Salvator is entitled to occupy the place of the originator of a style noted for certain qualities of poetic feeling. The influence of the school of the Naturalists had more important results than that of the Eclectics, for it affected to some extent the leading masters of the Spanish school.

At Rome, contemporaneously with Domenichino, Guido, and other leading masters of the schools of the Eclectics and Naturalists, the three following artists elevated landscape-painting to a high position—Nicholas Poussin (q. v.), a Frenchman (1594—1665); Claude Gellée, also a native of France (1600—1682), called Claude Lorraine (q. v.); and Gaspre Duchet, named Gaspar Poussin (q. v.), born in Rome, but the son of a Frenchman (1613—1675). Among the great masters who occasionally practised landscape-painting as a distinct branch of art, the earliest were Titian and Giorgione; the Carracci (particularly Annibale) carried out their style with considerable success; the landscapes of Domenichino are esteemed, and other scholars of the Carracci turned their attention in that direction. The reputation of N. Poussin is principally based on his figure-pictures, the subjects of which were mythological and Scriptural. Into these pictures he endeavored, with considerable success, to infuse the classical style; but his compositions were generally arranged with a large space of landscape background, which was in many cases not the least important portion of the picture; and these and the pictures he painted falling strictly under the class of landscapes, are distinguished for largeness of style and poetic feeling. Claude and Gaspar directed all their efforts to landscape, and attained to high eminence in that department of art.

The earlier specimens of painting in Spain resemble in style the works of the old German painters, who seem to have disposed of many of their pictures in that country, while Spanish art of the 16th c. was modelled on that of Italy, Titian and Raphael being the masters studied; but when works of the Spanish school are spoken of, those executed in the 17th c. are always understood to be referred to, as it was then that Spanish art became entirely national in feeling and style, and that is the period in which the best works of the school were produced. The two most distinguished Spanish painters are Don Diego Velasquez (q. v.), (1599—1660), and Bartholomé Esteban Murillo (q. v.), (1618—1682). The portraits of the former are characterized by truthful and dignified expression, great breadth and vigorous handling, and rank with the best works of that class of any school; while the Scriptural subjects of the latter, which are noted for tender expression, rich color, and powerful light and shade, may be classed with similar works by Rubens and Van Dyck. Spagnoletto, a Spanish painter, has already been referred to as a leading artist of the school of the Naturalists at Naples. Alonzo Cano (1601—1667), Francisco Zurbarán (1598—1662), and Claudio Coello (born between 1630 and 1640—1693), have a high reputation. No name of a Spanish painter of eminence occurs after the close of the 17th century.

Very soon after the period when the Eclectic and Naturalistic schools arose in Italy, a revival of art also occurred in the Netherlands. This was very different in its effect from the revival in Italy, the only results from which were academical imitation of the older masters, and coarse naturalism, either separately or combined in varied proportions; while the works of the artists of the Netherlands executed about the same period, though they do not exhibit the high qualities found in the compositions of the Italian masters of the best period, possess many new and attractive features—freedom, originality of treatment, attention to the peculiar character of individual life, and the daily intercourse of men with each other in all its variety, and the study of nature, brought out with truth and delicacy of execution. Two important schools of art were established by this movement—the Flemish and the Dutch. The Flemish school flourished in Brabant, where the Roman Catholic faith—then making strenuous efforts to oppose

the Reformed religion—still retained and actively employed art in its service. The Dutch school flourished in Protestant and republican Holland, where the artist, having to trust to private encouragement, painted, for the most part, familiar subjects from everyday life; and in place of altar-pieces for churches, and large historical and allegorical pictures for palaces, produced the subjects then in demand—portraits, genre pictures, or works in which life and manners are depicted in various phases—landscapes with and without figures, sea-pieces, battle-pieces, compositions representing hunting, animals, game, &c.

The catalogue of the names of the able artists of these two schools is long; in the Flemish school, those who stand highest are Peter Paul Rubens (q. v.), (1577—1640), Anthony Van Dyck (q. v.), (1599—1641), David Teniers (q. v.) the Younger (1610—1690), F. Snyders (1579—1657). The following are the most eminent in the long list of artists of the Dutch school: Rembrandt (q. v.) (1608—1669), Vanderhelst (1613—1670), Albert Cuyp (q. v.), (1605—1691), Terburgh (1608—1681), A. V. Ostade (1610—1685), J. Ruysdael (q. v.), (1630 or 1636—1681), Hobbema (1629—1670), P. Potter (1625—1654), K. du Jarden (1635—1678), Jan Steen (q. v.), (1636—1689), G. Metz (1615—1658), F. Mienis (1635—1681), W. Van de Velde (1633—1707), A. Van der Neer (1613—1684), P. Wouwermans (q. v.), (1620—1668).

Painting has been practised for a very long period in France; but there, as in Spain and in Britain, the marked preference shown in early times by the sovereigns of the country for the works of foreign artists, their undervaluing native talent, and their directing it into a channel supplied from a foreign source, had the effect of neutralizing it as the exponent of national feeling. Francis I. is acknowledged to have been a patron of art; he had a desire to possess fine works, and he liberally rewarded able artists, but his patronage was almost entirely confined to foreigners.

Louis XIV. did what he could to place French art above that of every other nation; but he had no knowledge of it himself; he did not comprehend its nature and true intention, and imagined that pictures if painted by Frenchmen must necessarily be national. Nevertheless, his influence was, on the whole, highly beneficial to French national art. He always showed himself desirous to employ native rather than foreign talent, and he encouraged and enlarged the Academy of Fine Arts, which had been founded at the commencement of his reign, under the direction of Lebrun. Although in many respects the principles and the regulations of the Academy tended rather to the perpetuation of debased Italian, than to the development of genuine French art; yet the bringing together of a body of influential French artists, was the measure most likely to foster the feeling of nationality and to lead to the foundation of a national school of art. In the 16th c., François Clouet was distinguished as a portrait-painter; and Jean Cousin as a painter, sculptor, and architect. In the 17th c., among many names, those chiefly deserving notice are Simon Vouet, the brothers Le Nain, N. Poussin, Claude Lorraine, Mignard, S. Bourdon, Le Sueur, J. Courtois (called Borgognone), and Coppel. Among these, the works of the brothers Le Nain alone possess national feeling and character, and they are held in very considerable estimation; those of the others were executed under the influence of foreign art; and excepting Claude's splendid landscapes, Poussin's learned compositions, and some of Borgognone's battle-pieces, hold a low position.

The works of Anthony Watteau (1684—1721) are truly national, excellent in execution, and very highly valued. This artist may be classed as at the head of the school of the 18th c.—the period in which art in France became really national. Not only did most of the painters of his school—which lasted till the end of the century when classic art ruled for a time—form their style upon the works of Watteau, but his influence also affected the British school, which arose soon after that of France was developed. Lancret (1690—1742) was the most successful imitator of Watteau; Pater 1696—1736 followed in the same course; Chardin (1699—1779), though influenced by him, had an original style of his own, and his works now stand high. The pictures of Boucher (1704—1770) exhibit the defects of the French school of the 18th c., unredeemed by the delicacy and grace, and high technical execution and truth of Watteau, Chardin, and Greuze (1725—1805), the last of whom sustained the character of French national art, and carried it into the 19th c., when it was re-established, after the classic school of David, founded at the Revolution, and patronized under the empire of the first Napoleon, had in its turn been laid aside. David (q. v.), (1748—1825), the leader of this school, carried his admiration of classic art to the length of substituting the study of statues the works by which the art of the ancients is chiefly known, for that of nature. He had numerous able pupils, several of whom, tired with this constant repetition of conventional form, recurred to nature, extended their range of subjects, and infused new vigor into the French school.

Among many distinguished artists that have maintained the fame of the French School during the present century the follow-

ing names may be mentioned: Géricault, Prud'hon, Leopold Robert, Delaroche (q. v.), Horace Vernet (q. v.), Ary Scheffer (q. v.), Eugène Delacroix (q. v.), and Ingres (q. v.). A number of artists, chiefly pupils of the above, now sustain the high position of French art in every department; while in that of landscape illustrative of French scenery, a branch of art never much studied in past times, great progress has been made, and the rise of this flourishing branch of French art is acknowledged by the French themselves to be due to the works of the English painter Constable, exhibited in Paris in 1824.

The English school was the latest national school that arose in Europe, for although the modern schools of Germany and Belgium are of still later date, having arisen in the present century, still they can scarcely be classed as new schools, but rather as revivals of former national schools. In England, as in France, foreign artists chiefly were in early times employed by the court and the nobles. Henry VIII. competed with Francis I. for the services of the greatest of the Italian artists, and permanently secured those of Hans Holbein, one of the most distinguished of those of Germany. Charles I. liberally patronized Rubens and Van Dyck; and if he had reigned longer, would in all probability, like Louis XIV., have founded a national school. But referring to the separate notices in this work of the foreign artists under their names respectively who were employed in this country, and to the article *MINIATURE PAINTING* for notice of several eminent native artists in that branch of art, it is only necessary here to touch on the subject of painting in this country from the time it acquired a truly national character.

At the beginning of the 18th c., art in Britain was at the lowest ebb; the career of Sir Godfrey Kneller (q. v.), (1648—1725 or 1726), the last of the foreigners, was drawing to a close; Sir James Thornhill (1676—1734), an Englishman, followed out the decorative kind of art on which Verro, La Guerre, and others were so much employed; but after his death, that debased style finally went down. The time had now arrived for native artists, if there were any entitled to the name, to assert their independence; and accordingly in 1734—1735, as many as from thirty to forty artists combined together in London, and instituted an academy for studying the human figure. About the same time a similar movement was going on in Edinburgh, the contract or indenture for establishing a school of art, dated 18th October 1729, and signed by seventeen artists, besides amateurs, is in the possession of the Royal Scottish Academy. The effort above referred to, of artists combining to found a Life Academy, was mainly due to William Hogarth (1697—1764), who, on this account, and from his first having developed, in a very high degree of excellence in his works, the leading characteristics of the English school, is justly entitled to be considered its founder. This combination led to these important results—it showed the artists their strength, and enabled them, after a probation of thirty-four years, to found the Royal Academy, an institution managed by artists, and intended to support and encourage a national school of art.

The means by which the Royal Academy proposed to attain its purpose were the following: 1, by founding a school where artists may learn their profession; and 2, by instituting an exhibition where, independently of private patronage and support, artists may bring their works directly before the public. Hogarth died four years before the Royal Academy was organized; but he powerfully contributed to its establishment by his exertions in bringing the artists together in 1734, by supporting the modern exhibitions at Spring Gardens, and by ridiculing by his pencil and pen the passion of the cognoscenti of the day for crying up as superior to the modern the doubtful specimens of old art which were largely imported and disposed of at great prices in numerous salerooms established for the purpose in London. As regards technical execution, and indeed in style generally, the English artists were at first indebted to the French school, which, in the commencement of the 18th c., was in great vigor. Hogarth himself, in these respects, looked closely at the works of Watteau, engravings from which were well known in this country in his time; indeed, Watteau's pictures were so greatly admired here that he came over and spent the year 1720 painting in London. But Hogarth, though alive to the qualities in art produced by others, ranks among painters as one of the most original, for he greatly extended the dramatic element in painting, and imparted an originality and vigor to it never before attained; and his example has led to that element being one of the leading features of the English school, as is exemplified in the works of Wilkie (q. v.), Leslie (q. v.), Stuart Newton, Bonington, and others; and those of many distinguished artists of the present day.

In the department of portrait-painting, many of the works of the British school rank with those of Titian, Van Dyck, and Velasquez, such, for instance, as Reynolds's portraits of Nelly O'Brien and Lady Hamilton, Gainsborough's Mrs. Graham and Mrs. Siddons, and some of Raeburn's heads, &c. While in that of landscape, the position of the English school is acknowledged

to be very high, its influence now strongly affecting the French school—this is proved by the works of R. Wilson, Gainsborough (q. v.), and Turner (q. v.), the last of whom, for wide range of subject, and rendering of atmospheric effect stands alone; Constable, whose powerful grasp of nature has excited the emulation of the French artists; Calcott (q. v.), Collins (q. v.), Nasmyth, J. Thomson, Muller, and others; and their successors, the artists of the day, who ably represent the English school. Animal-painting has also been elevated to a high position. And an important department, that of Water-color Painting (q. v.), originated in England, and has there attained higher excellence than elsewhere.

Painting is cultivated with success and receives much encouragement in America, but there the features that mark a national school have not yet had time for development. From the close connection between Britain and America, the art of the latter country was naturally influenced by and became assimilated to that of the former. America may, however, justly take credit for having contributed in no small degree to strengthen the British school of art, as several very able members of the Royal Academy were Americans. Benjamin West (1738—1820) was one of the original members, and elected President of the Royal Academy in 1806.

J. S. Copeley (1737—1815), elected R.A. in 1799; his 'Death of Chatham,' and 'Defence of St. Heliers, Jersey, against the French, and Death of Major Pierson at the moment of Victory,' are excellent works, and as such were conserved in the National Gallery, London. C. R. Leslie (1794—1859) was born in London of American parents; but in 1799, went to Philadelphia, where he was educated. Returning to London in 1811, he entered the schools of the Royal Academy; was elected academical in 1826, and professor of painting in 1848. G. S. Newton (1794—1885)—he was admitted a student of the Royal Academy in 1821, and elected academical in 1832. Washington Allston (1780—1843) was elected an associate in 1818, but afterwards returned to America, where he died. With the exception of the last named, the feeling evinced in the works of all these artists, influenced by study and continued residence, was essentially English; indeed few have equalled Leslie and Newton in their power of embodying the various incidents made national by English poets; and in none of their works can anything be set down as contributing in any degree to the foundation of a national American school. There is every reason to think, however, that such a school is being gradually evolved, and will soon be developed.

Already something like originality of a national kind is exhibited in landscape painting, in which some American artists are endeavoring to embody scenes embracing a vast extent of country, or of extraordinary magnitude—such as those met with in the Andes, at Niagara, or exhibited by floating icebergs; and American literature, having now assumed imposing proportions, and great historical events having recently taken place, illustrations of American poetry and pictures of stirring national events will be called forth; and able American artists will doubtless be found to embody them and create a school truly national.

A general survey of painting at the present time exhibits the following aspect and arrangement: 1. A school in Germany, which arose during the present century, ostensibly a revival of the old national, but truly modelled on the early Italian school, the religious element being prominent. Its principal works are mural, of large dimension, and mostly executed in fresco or on a kind of fresco lately invented, called *silica* or water-glass painting, from a vehicle of that kind being used. Invention, composition, grouping, and powerful and correct drawing, characterize the modern German works; but being of necessity executed from cartoons, they are deficient in that amount of individual expression, and natural color and effect, that can only be attained by a direct and continued reference to the object represented. 2. A Belgian school, which arose in the present century, and is also a revival of the earlier national schools. Some of the Belgian artists lean to the manner of the very early Flemish school, others to that of which Rubens was the head. The greater portion of the Belgian works are easel-pictures, and many of them rank high for individual expression, color, and technical execution.

3. A French school, exhibiting in active operation the various styles that have at different periods prevailed in that country, sometimes modified or adapted to the taste and feeling of the times. The works of the French school of the eighteenth century were utterly condemned by French artists at the close of that and commencement of the present century. They would tolerate nothing but what they called classic art. *L'Ecole classique* as it was styled, was in its turn supplanted by *l'Ecole romantique*. Now, however, all styles are tolerated, even those of foreign schools—for instance, the English school of landscape—and there can be no doubt that, by the extensive range of subject, invention, drawing, and other high qualities the French artists display in their works, they have now raised that school to a very high position. 4. A British school, which has been in existence as a national school nearly as long as that of France, undisturbed by the

convulsions that affected it. Vitality in art is maintained by close reference to nature, and this has all along been the leading characteristic of the English school; while the tendency of the artists at present is, taking advantage of the aid of science, which has lately discovered photography, to study nature with still greater earnestness and care. The high claims of the British school, long denied abroad, are now fully admitted. Formerly, foreigners never classed a British school among those of Europe, but now this is invariably done. One of the most popular writers on art in France, Théophile Gautier, in his work, *Les Beaux-Arts en Europe*, divides the art of the world into four strongly defined zones—viz., Great Britain, Belgium, Germany, and France—Britain being distinguished by 'individuality,' a potent element in art; Belgium, by 'skill;' Germany, by 'ideality;' and France, by 'eclecticism,' or a selection and combination of the qualities of all other schools.

Regarding technical modes or processes of painting, reference is made to the separate notices under **Fresco**, **ENCAUSTIC**, **MINIATURE PAINTING**. The period when the method of mixing up colors with oil was introduced, and the artists to whom the invention is attributed, have been already alluded to. It is necessary, however, to enter on some details touching the mechanical processes in oil-painting, the branch of the art that occupies the most prominent position; and the practice of cleaning and restoring pictures.

The implements used by a painter in oil are charcoal, chalk, or lead pencils, for drawing the outline; hair-pencils or brushes of various sizes, made of hog's bristles or finer hair, such as sable; a knife or spatula to mix the colors, and a palette or small table of thin wood, to be held in the left hand, on which the colors and tints are placed and mixed; an easel or stand for supporting the picture is also required, and a light rod for steadying or resting the hand on. Large pictures are always executed on canvas, stretched tightly on a frame, and primed or coated with paint. Small pictures are often painted on boards or panels, generally of hard wood, such as oak or mahogany, and similarly primed or prepared; but canvas, even for small works, seems at present to be generally preferred. Panels are apt to twist, or warp, or split, and in the event of the surface of a picture chipping or breaking off from the ground, the damage can be more easily remedied, and its progress stopped, when the picture is on canvas, by re-lining.

The color of the ground of the canvas or panel has been the subject of much diversity of opinion among artists in different countries and at various periods; and it is certainly a matter of great importance, as it affects the general color of the work, or makes it necessary for the artist to adopt a peculiar style of working. The color of the ground used by the early masters was white, or nearly pure white. This arose from tempera or size being the medium first used in painting, and a pure white ground prepared with size was necessary for that kind of work. This practice, except as regards the Venetian school, continued till the decline of Italian art. Dull red was the universal color adopted in the eclectic, Naturalist, and late Italian schools, and this is one of the causes of the works of these schools being characterized by blackness and heaviness; and at the same time, it is certain that red grounds were also used by many of the best Venetian painters, in whose works these defects are never found, probably from having used an impasto or body of color sufficiently powerful to bear out on the ground. A dark ground affords a facility for working expeditiously, and that, probably, was the principal cause for its being adopted. The Dutch and Flemish painters generally used light grounds; some of them light-brown, nearly the color of oak. Van Dyck occasionally used gray, and sometimes, when he painted in Italy, dull-red grounds. In the British school, light grounds are preferred. Some artists use smooth canvas, others prefer it rough, and avail themselves of the texture to increase the richness of the surface of their work.

All these varieties in the materials are called for in consequence of the numerous styles or modes adopted by painters in oil colors. Every artist has his peculiar way of working, and in bringing out the color or effect, or special quality in his picture, by which the feeling or idea of the subject he conceives is expressed. No two artists—imitators and copiers are not referred to—produce their tints by mixing colors in the same proportions, nor, indeed, by using the same colors; and it is difficult to lay down general rules for the execution of works, seeing that depends very much on individual feeling and appreciation. The design or drawing is first outlined on the canvas, if it is light, with charcoal, or with white chalk when it is dark, and these lines are easily dusted off or rubbed out when corrections are made. It is then put in with black chalk or a lead pencil. Not many years ago it was the practice of painters, particularly landscape-painters—Nasmyth, for instance—to rub in the design with some brown color, such as a tint composed of burned sienna and black; but this practice is not much adopted now. Some artists make but a slight outline, and paint—or, as it is called technically rub—in the subject in a

bold, rough manner, afterwards gradually finishing it up; others draw the design very carefully, and work the picture up in portions, finishing or nearly finishing one portion before commencing another. In arranging the colors, or as it is called, setting the palette, many artists use a great variety of colors, others produce rich tones with few colors; some mix up tints in various gradations, others place the colors on the palette, commencing at the outer edge with white, followed by yellows and burned sienna (a reddish brown), then reds, including lakes, such as pink, madder, next blue, and lastly black, and merely mix up the tint on the center of the palette with their brush, as they proceed.

In laying the colors on the canvas, the painter with his brush mixes or dilutes them with what is called a vehicle or medium. Here, again, the practice of artists is very varied; and this is a matter of importance, as the tone and quality of the picture, as regards texture or surface and transparency, is much affected by the medium employed, and the manner of using it. The durability of the work also depends very much on the medium and the artist's management of it. A medium composed of mastic varnish and drying or boiled linseed oil, named *magilp*, is that most generally used. This mixture coagulates or forms a jelly, and has the advantage, when placed on the palette, of not running off it, or mixing with the colors when the palette is not held level. Some painters prefer using raw linseed oil mixed with a dryer, such as litharge, or drying oil mixed with turpentine, or copal varnish and turpentine, or copal varnish and oil, with mastic varnish added, to make it coagulate. Other ingredients are often mixed with the medium, to give a thick consistency to the paint, such as fat or thickened nut oil, paste, &c.; and various preparations sold by artists' colormen are much used; for instance, Roberson's medium, and Siccacif de Harlem, a preparation imported from Paris. The mode of using the medium is of great consequence; some apply it very sparingly, others, particularly those who prefer *magilp*, or a medium that coagulates, employ it lavishly. By the first method, firmness and decision of touch may be exhibited, by the latter, richness and brilliancy of tone; the excess tends to produce, in the one case, a hard and dry surface, and the want of the protection that varnish mixed with the color gives against atmospheric action; the other induces a surface having a horny appearance, and a tendency to darken, or crack, or open up.

Arresting the decay of pictures, and repairing, or, as it is styled, restoring them, after they have suffered from age or bad usage are matters which engage much attention. There can be no doubt that many paintings of vast importance have been saved by the care and skill of those who have earnestly devoted themselves to that kind of work; but picture-cleaning is now a trade followed in numerous instances by ignorant pretenders and quacks, who hold out that they possess some means by which they can freshen a picture, and restore it to the state it was in when originally executed. Generally speaking, the great extent to which this business is carried on is owing to the credulity of those who dabble in collecting old pictures, one great incentive to which being the hope of picking up, or discovering, some picture of great value concealed under the dirt and discoloration acquired in a long course of years; but, nevertheless, there can be no doubt that many proprietors of works of art who collect from far higher motives, are remarkably prone to call in the picture-cleaner when his services are anything but necessary or beneficial.

The late Sir Edwin Landseer, R.A., when examined by the Select Committee of the House of Commons appointed to inquire into allegations of damage by cleaning, sustained by the pictures in the National Gallery of London (Report and Evidence ordered to be printed, 1858), stated in the following terms, his idea of this rage for picture-cleaning, or rather picture-destroying: 'The first thing, whenever a picture is sold, I think, is, that it goes to a picture-restorer, or a picture-liner, or a picture-cleaner, no matter what its condition is. It is exactly the same thing as when you buy a horse; your groom says he will be all right when he has a dose of physic through him, whether he wants it or not.' The mania for picture-cleaning is not confined to this country; it is extensively carried on with even more ruinous consequences abroad, particularly in Italy, where there is a large traffic in old, and few commissions for modern works, and where in many of the public galleries one or more picture-cleaners, for whom work must be found, are attached as permanent officers.

The process of picture-cleaning, or the removal of the old varnishes or other incrustations by which a painting may be obscured, is effected either by mechanical or chemical means. The first method is accomplished when the varnish on the surface is mastic, by rubbing with the fingers the surface of varnish when in a dry state, by which action it is brought off in a fine white powder; or by scraping or erasing the surface with sharp steel instruments when the surface of the picture is tolerably smooth.

The first of these processes is the best that can be employed; but when the surface is rough or unequal, the prominent portions are apt to be over-rubbed; erasing or scraping is often practised

in Italy, but rarely in this country. The chemical means consist in the application of solvents, chiefly alkali, or alcohol, to dissolve the old varnish. The danger here is, that the action of these solvents is not always stopped with sufficient promptness and dexterity, and part of the surface of the picture is taken off; consequently it is by this latter process that most destruction is caused. For the various methods employed in picture-cleaning, the Report and Minutes of Evidence, already referred to, may be consulted, and *Lejeune's Guide*.

See *History of Painting, Ancient, Early Christian, and Medieval*, from the German of Woltmann and Woermann, edited by Sidney Colvin (1880); *Classic Painting*, by Poynter and Head (1880); and the standard works of Vasari (Florence, 1568); Borghini (Florence, 1584); Rodolphi (Venice, 1648); Zanetti (Venice, 1771); Lanzi (1792); Bohn's edition of Roscoe's translation; Von Rumohr (Berlin, 1827); Kugler's *Hand-book of Painting, Italian Schools* (ed. by Eastlake, 1855), *German, Flemish, and Dutch Schools* (1846), *Spanish and French Schools* (1848); *History of Painting in Italy*, by Crowe and Cavalcaselle (1876); *Hand-book for Young Painters*, by C. R. Leslie, R.A. (1855); Ruskin's *Modern Painters* (1843—1860).

PAINTING (HOUSE), is one of the useful arts, combining much that is artistic with much that is absolutely necessary. The primary object of painting houses, or parts of them, either internally or externally, is to preserve them from decay—to cover the parts liable to suffer from exposure with a durable composition. That now used is made of ground white-lead mixed with linseed oil. This produces white paint, which forms the basis of all others. The various colors given to it are produced by the grinding of pigments (or *stainers*) along with the white-lead. The commonest of these are ochres (yellow and red earths), lampblack, Venetian red, umber, Prussian blue, chrome, vermilion, &c. Substances called driers are also mixed with the paint, such as spirits of turpentine, boiled oil, litharge and sugar of lead ground in oil. Paint may be laid on any material—stone, wood, iron, and plaster being the most usual in buildings. It has the effect of preserving these, by filling up the pores in them, and forming a coating on which the moisture of the atmosphere does not act. The paint is laid on in several *coats* or layers, each being allowed to dry before the next is applied. The usual number of coats for new wood or plaster varies from three to six. Five coats form a good and lasting protection from the weather. Plain painting is generally finished with a coat prepared with a mixture of oil of turpentine, which takes off the gloss from the paint, and leaves the surface quite *mat* or dead. This is called *flattening*.

A very common form of decoration in all ages has been to imitate the veins or colors of marbles, and the *grains* or marks of growth of various woods. In modern times, these arts form a separate branch of house-painting, some men being *grainers*, others *marblers*, &c. The mode in which these imitations are produced is by forming a *grounding* of several coats of plain paint—usually four—and applying the coloring coat over this. In marbling, the coloring matter is marked and veined with *feathers*, in place of brushes; and in graining, steel combs are used. When the surface is dry, it is protected with one or more coats of copal varnish.

Besides painting, the decorator uses paper-hangings for adorning the walls of houses. These are applied to the walls with paste. Size-coloring is also used; the coloring matter in this case being mixed with strong Size (q. v.) in place of oil; but this has the disadvantage of being easily acted on by moisture. It is often used for the ceilings of common rooms, and for the walls of kitchens and servants' apartments, being much cheaper than oil-paint. In ancient times, in Greece and Rome, wax was used for mixing the colors with; but although there are many very fine specimens of Roman paintings still preserved on the walls of the houses of Pompeii, the mode in which these decorations were applied is not now known.

PAINTS, PAINTERS' COLORS, or PIGMENTS. These names are applied to the prepared or unprepared compositions by which wood, stone, and other materials are coated with a preservative surface of oil, mixed with an earthy matter, to give it color and consistency; also to the materials used by artists to produce the colored surfaces of their pictures. The art of painting, in its primitive state, consisted merely in applying such natural, mineral, and vegetable colors as were spontaneously yielded, without any vehicle to render them permanent; consequently, they had to be renewed as often as they were rubbed or washed off from the surfaces to which they were applied. The paints now in use are nearly all mixed with a liquid vehicle, and are applied in the liquid state. The mixing materials are varied according to the requirements of the work. Thus, for some kinds of decorative work, and for water-color drawings, gum, glue, size, or other adhesive materials dissolved in water, are employed; whilst for the painting of buildings, &c., and for oil-paintings, oils of various kinds are used for mixing and thinning the colors. Thus, for painted work exposed to the weather, it is found that

linseed oil boiled with the sulphates of lead (litharge) or zinc, or with acetate of lead (sugar of lead), is the best. The preparation of boiled oil is one requiring particular care, as it is desirable to have it bright and clear. Hence the proportions of the metallic salts are much varied by different manufacturers, and by some various other ingredients are added. The time of boiling, and the method of filtering, are also much varied.

For indoor work, plain linseed oil and oil (spirit) of turpentine are used; if a *glossy surface* is wished, the linseed oil must be in excess; if a *dull or flattened surface*, then the quantity of turpentine, or *turps*, as it is often technically called, must be increased; and it is usual to add a small quantity of ground litharge and sugar of lead, which are prepared for this purpose, and sold under the name of *Driers*. For artists' colors, very fine linseed or nut oil is used, unboiled, and in small quantity, and turpentine is employed to dilute them. Paints for very rough purposes, such as ship-work, stone walls, &c., are often mixed with whale oil boiled with white vitrol (acetate of zinc), litharge, and vinegar, and they are diluted with common linseed oil and turpentine.

Most of the paints used for ordinary purposes are composed first of the coloring matter, then of a quantity of white-lead, with which and the oil they are worked into a paste of the shade required, and afterwards thinned down with oil and turpentine when used. The white-lead which thus forms the basis of most paints, and by itself a color, is a carbonate and oxide of the metal, produced by exposing pieces of lead to the action of the steam of acetic acid in beds of fermenting tan. It is the principal white paint used, but is liable to discoloration from the gases contained in impure atmospheres. Other white pigments are prepared from the oxide of zinc, and the carbonate and sulphate of barytes.

Pale yellow is made with chromate of strontian, orange-yellow, with sulphuret of cadmium, whilst several varieties of this color are produced by chromate of lead, sulphuret of arsenic, or king's yellow, and various native earths in which silica and alumina are combined with oxide of iron. Amongst these are Yellow Ochre, Oxford, Roman, Stone, Orange, Indian, and American Ochres. *Reds* are either purely mineral, or they are *lakes*, i. e., organic colors precipitated on alumina bases. Of the latter, there are madder-lakes, prepared from madder-roots, and carmine-lakes, prepared from cochineal; of the former, vermilion (bisulphuret of mercury), Indian red (a native oxide of iron), Venetian red (also an oxide of iron), red lead (red oxide of lead or *minium*). A very beautiful red is used by artists called palladium red; it is formed of ammonio-perchloride of palladium. *Blues* consist of the artificial ultramarine, and for artists' purposes, of the real ultramarine, also the silicate of cobalt, and for water-colors, indigo and Prussian blue. *Greens* are either produced by mixtures of yellows and blues, or they are made directly from the phosphates, carbonates, acetates, and arsenites of copper, also from the sesquioxide of chromium, and from *terre verte*, a native mineral, consisting of iron, silica, potassa, and magnesia. The last two are the best for artists.

Browns are numerous, and various in their composition. Decomposed peat, burned madder, burned Prussian blue, burned terre verte, asphalt, manganese brown, catechu, umber (which is an oxide of iron with manganese), and mummy, or the asphalt mixed with other matters taken from Egyptian mummies, are amongst the best known and most used. *Blacks* are made of Lamp-black and Bone-black (q. v.), peroxide of manganese, and blue-black, which is made of the charcoal of burned vine twigs.

In all cases, the coloring materials of paints require to be very finely ground, and as many are very poisonous, great care is required in their preparation, and several forms of mill have been invented for the purpose. The principle upon which all are made is to secure the operator from the poisonous dust and exhalations, and to reduce the coloring material, if ground dry, to an impalpable powder, or if mixed with the oil, to a perfectly smooth paste.

PAISIELLO, GIOVANNI, an eminent musician, son of a veterinary surgeon at Taranto, was born in 1741, and received his musical education in the Conservatorio St. Onofrio at Naples. Of his earlier operas produced at Naples, the most celebrated was *Dal Finto al Vero*, composed in 1777. Some of his best works, particularly *Il Barbiere di Serriglia*, were written during an eight years' residence at St. Petersburg. At Vienna, he composed twelve symphonies for a large orchestra, and the opera buffa, *Il re Teodoro*. Between 1785 and 1799, he produced a number of operas for the Neapolitan theater, and was appointed by Ferdinand IV. his *maestro di cappella*. In consequence of having accepted under the revolutionary government the office of national director of music, he was suspended from his functions for two years after the restoration of royalty, but eventually restored to them. In 1802, he went to Paris to direct the music of the consular chapel; but the indifferent reception shortly after given to his opera of *Proserpine*, led him to return to Naples, where he died in 1816. His compositions are characterized by sweetness

and gracefulness of melody, and simplicity of structure. Besides no fewer than ninety operas, P. composed masses, requiems, cantatas, an oratorio, instrumental quartets, harpsichord sonatas, concertos, and a highly-praised funeral march in honor of General Hoche.

PAISLEY, a municipal and parliamentary burgh, and an important manufacturing town of Scotland, in the county of Renfrew, on both banks of the White Cart, three miles above its junction with the Clyde, and seven miles west-south-west of Glasgow by railway. The progress of the town has been much hindered by the fact that it was bankrupt for nearly thirty years. A bill was passed in 1872, by which a settlement was effected, and the town property restored to the corporation. Since then, extensive improvements have been made. An abundant supply of water is brought from the Gleniffer Hills, and more recently from Rowbank.

By far the most interesting edifice is the abbey. It was founded by Walter, the High Steward of Scotland, about 1163, for a prior and 13 monks of the Cluniac order of reformed Benedictines, and was dedicated to St. James, St. Mirren, and St. Milburga. It was the burying-place of the Stewarts before the accession of that family to the throne, and was occasionally used by them afterwards as a place of sepulture. It was raised to the rank of an abbey in 1245. It was burned by the English in 1307, and was much destroyed in 1561. The building is in the First Pointed style. The nave, of six bays, which is still used as the Abbey Parish Church, was carefully and thoroughly restored by the removal of unsightly galleries and otherwise in 1862. The choir and transepts are in ruins. Near the Abbey is a monument to Wilson the ornithologist, who, like John Wilson (Christopher North) and Tannahill, were natives of Paisley.

Other edifices are the County Buildings and Prisons, a quadrangular pile in the castellated style; the Neilson Educational Institution, a noble bequest, built in the form of a Greek cross, and surmounted by a fine dome; the Infirmary; the School of Design; and the various banks. The Grammar School was founded by King James VI., and the present building was completed in 1864. In 1870 a Free Public Library and Museum was presented to the town, and is maintained by the community under the Free Libraries Act; and by a similar act of liberality, its amenity was increased by a pleasure-ground named the Fountain Gardens. In 1873 a native of Paisley bequeathed £20,000 for the erection of a town hall, which was completed in 1880; it is a handsome classical building near the Abbey. A large public park was presented to the town, and opened in 1877; and an observatory was presented in 1882. P. possesses a trust for the education of boys, the revenue of which amounts to £500.

In the beginning of the last century, the principal manufactures were coarse linens and chequered cloths. About the middle of that century, the weaving of linen and of silk gauze became the staple manufactures. In 1784 silk gauze was manufactured to the value of £350,000, and employed 5000 looms. Shawls, which used to be a principal and are still an important article of manufacture, began to be made here in the beginning of the present century. Within recent years the annual value of the shawl trade of P. was estimated at about £1,000,000 sterling, but it has now greatly declined. Cotton thread is manufactured on a most extensive scale; indeed P. may be considered the seat of the thread manufacture for the home and American markets. Different varieties of tartan cloths, handkerchiefs, carpets, &c. are made; soap, starch, and corn flour are largely manufactured; dyeing is carried on by several firms on an extensive scale; and power-loom factories, print-works, machine shops, bleach-fields, ship-building yards, &c. are in operation in the town and vicinity. At the St. James' Day Fair, horse-races, originated by act of the bailies of the burgh in 1608, are held. Pop. (1871) 48,257; (1881) 55,642.

PAKS, a market-town of Hungary, in the county of Tolna, 60 miles south-south-east of Pesth, on the Danube. The river is here very winding, and the eastern bank a desert and useless morass. The town is frequently subject to inundations. Pop. 11,100.

PALACE, this title is applied, with few exceptions, in this country to houses occupied by royal personages only. In Italy the name is given to all fine dwellings.

PALACKY, FRANTIŠEK, a Bohemian philologist, critic, and historian, was born 14th June 1798 at Hodslavitz, in Moravia, and studied at Presburg and Vienna, confining his attention chiefly to philological and historical investigations. In 1831 he was appointed by the states of Bohemia historiographer to that country, and was intrusted with the compilation of a general history of Bohemia. In furtherance of this work, he ransacked all the libraries and archives in Bohemia, and made long visits to Germany and Italy in search of materials. He took part in the political agitation of 1848, and was the leader of the Slav or national party as opposed to the German at the Diet of Kremsier, after the dissolution of which he returned to his literary labors. His

great and justly celebrated work, *History of Bohemia* (In German and Bohemian, Prague, 1836—1897, 5 vols.), was received with enthusiasm by the whole Bohemian nation. Besides an early treatise on aesthetics, P. published many volumes of documents pertaining to Bohemian history, and a series of monographs on the same subject; a work on the most ancient monuments of the Czech tongue; an account of a literary tour to Italy in 1837; and in 1872 his 'Political Testament.'

'Father P.,' as he was fondly called by his Czech fellow-countrymen, was beloved by them as the first to give access to the real history of Bohemia; and though himself a Protestant, was regarded by Catholics with perfect confidence. Throughout life a zealous contender for the crown rights of Bohemia, he persistently but vainly opposed the reconstruction of Austria on a German-Hungarian basis; and when in 1861 he was elected into the Austrian House of Lords, he declined to attend. He died in May 1876.

PA'LADIN, a term originally derived from the Counts Palatine, or of the Palace (see **PALATINE**), who were the highest dignitaries in the Byzantine court, and thence used generally for a lord or chieftain, and by the Italian romantic poets for a knight-errant.

PALÆA'STER (Gr. ancient star-fish), a genus of star-fish, peculiar to the Silurian period, which in general appearance resemble the living brittle stars, but when more minutely examined, present so many anomalies, that they cannot be referred to any existing family. Five or six species have been described.

PALÆO'GRAPHY (Gr. *palaios*, old, and *graphé*, writing), the science of ancient writings. It comprehends not merely the art of reading them, but such a critical knowledge of all their circumstances as will serve to determine their age, if they happen to be undated, and their genuineness, in the absence of any formal authentication. For these purposes, the palæographer needs to be acquainted with the various substances, such as bark, leaves, skins, paper, &c., which have been used for writing; with the various manners of writing which have prevailed, and the changes which they have undergone; with the various forms of authenticating writings, such as seals, signets, cachets, signatures, superscriptions, subscriptions, attestations, &c., which have been employed at different times; with the various phases through which the grammar, vocabulary, and orthography of the language of the writing with which he is dealing, has passed; and with more or less, as the case may be, of the history, laws, institutions, literature, and art of the age and country to which the writing professes to belong.

Palæography may be said to have been founded by the learned French Benedictine, Jean Mabillon, whose *De Re Diplomatica*, first published in 1681 in 1 vol. fol., reprinted in 1709, and again in 1789, in 2 vols. fol., is still, perhaps, the most masterly work on the subject. Along with the *Nouveau Traité de Diplomatique* (Par. 1750—1765, 6 vols. 4to) of the Benedictines of St. Maur, and the *Éléments de Paléographie* (Par. 1838, 2 vols. 4to) by M. Natalis de Wailly, it is the great authority for French palæography. English palæography is perhaps less favorably represented in Astle's *Origin and Progress of Writing* (Lond. 1803), than Scottish palæography in Anderson's and Ruddiman's *Diplomata Scotica* (Edin. 1739). Muratori treats of Italian palæography in the third volume of his great work, the *Antiquitates Italicae Medii Aevi*; and among later works on the same subject may be mentioned the *Diplomatica Pontificia* (Rome, 1841) of Marino Marini. The palæography of Greece is illustrated in the *Palæographia Græca* (Par. 1708) of Montfaucon. Spanish palæography may be studied in the *Bibliotheca de la Polygraphia Española* (Mad. 1788) of Don C. Rodriguez.

Of works on German palæography, it may be enough to name Eckard's *Introductio in Rem Diplomaticam* (Jen. 1742), Heumann's *Commentarii de Re Diplomatica* (Norimb. 1745), Walther's *Lexicon Diplomaticum* (Gott. 1745), and Kopp's *Palæographia Critica* (Manh. 1817). Hebrew palæography has been elaborated by Gesenius in his *Geschichte der Hebräischen Sprache und Schrift*, and other works. The great work on palæography generally—one of the most sumptuous works of its class ever published—is the *Palæographie Universelle* (Par. 1839—1845, in 5 vols. fol.) of M. J. B. Silvestre. See **BLACK LETTER**, **CONTRACTIONS**, **PALIMPSEST**, **PAPYRI**.

PALÆO'LOGUS, the name of an illustrious Byzantine family, which first appears in history about the 11th c., and attained to imperial dignity in the person of **MICHAEL VIII.** in 1260. This emperor successfully undertook many expeditions to Greece and the Archipelago, and used his utmost endeavors to heal the schism between the Roman and Greek Churches, though with exceedingly little success. His successor on the throne was his son **ANDRONICUS II.** (1282—1329), under whose reign the Turks commenced in earnest a series of assaults on the Byzantine dominions. Andronicus attempted to oppose them with a force composed of mercenaries, but his success was very doubtful, as these

troops, with perfect impartiality, attacked both his enemies and his subjects. To pay them he was compelled to levy such imposts as went far to destroy Byzantine commerce.

He associated his son, MICHAEL IX., with himself in the government, and was dethroned by his grandson, ANDRONICUS III. (1328—1341), an able warrior and wise ruler, who repeatedly defeated the Bulgarians, Tartars of the Golden Horde, and the Servians, and diminished the oppressive imposts of the previous reign. He was, however, unsuccessful against the Catalans in Greece, and the Turks during his reign ravaged Thrace as far as the Balkan. He was greatly esteemed by his subjects, and well merited the title of 'Father of his Country,' which they bestowed upon him. His son, JOHN VI. (1355—1391), a weak and voluptuous prince, attempted in vain both by force and bribery to stop the progress of the Turks; at last the pope, moved by his urgent entreatise, which were backed by a promise to submit the Greek Church to his (the pope's) supremacy, urged the Hungarians and Servians to arm in defence of the Greek emperor, but the result was only an additional triumph to Sultan Amurath. The imbecile emperor was several times deposed, and on his final reinstatement by the sultan, acknowledged himself as his vassal for the capital and a small tract along the Propontis and Black Sea. Indeed, so degraded had the Byzantines become, that they obeyed the Sultan Bajazet's summons to aid him in reducing Philadelphia, the last Greek stronghold in Asia Minor. His son, ANDRONICUS IV. (1355—1373), who had been associated with him in the government, died in exile.

MANUEL II. (1391—1425) pursued the same tactics as his father John VI., and with the same result. The allied army of the Hungarians, Germans, and French, which he had summoned to his aid against the Turks, was totally routed at Nicopolis by Bajazet, and Constantinople itself closely besieged. The invasion of Asia Minor by Timûr, however, compelled the sultan to withdraw his whole force, and his subsequent defeat and capture at Angora in 1402, and the contests among his sons for the supremacy, gave the Greek empire a breathing space. Having aided Mohammed I. in his contests with his brothers, Manuel was, by the grateful sultan, presented with some districts in Greece, Thessalonica, and on the Euxine. JOHN VII. (1425—1449), on being pressed by the Turks, again held out to the pope the old bait of the union of the Greek and Western Churches under his sway, and even presented himself at the council at Florence, where, in July 1439, the union of the churches was agreed to. But on his return to Constantinople, the opposition of the Greek ecclesiastics to the union, supported by the people, rendered the agreement of Florence a dead letter. The pope, however, saw that it was for his interest to fulfil his part of the agreement, and accordingly stirred up Wladislas of Hungary to attack the Turks (see JAGELLONS), but this act only hastened the downfall of the Palæologi.

John's brother, CONSTANTINE XIII. (1449—1453), a heroic scion of a degenerate race, accepted the crown after much hesitation, knowing his total inability to withstand the Turks, and even then took the precaution of obtaining the sultan's consent before he exercised the imperial authority; but some rebellions in Caramania which now occurred, baffling Sultan Mohammed II.'s efforts to quell them, the emperor was willingly persuaded by his rash advisers that the time had now arrived for rendering himself independent of the Turks. The attempt, however, only brought swifter destruction on the wretched remnant of the Byzantine empire, for Mohammed invested the capital by sea and land, and after a siege, which lasted from 6th April to 29th May 1453, Constantinople was taken by storm, and the last of the Palæologi fell fighting bravely in the breach. A branch of this family ruled Montferrat in Italy from 1306, but became extinct in 1533. The Palæologi were connected by marriage with the ruling families of Hungary, Servia, and the last of the family married Ivan, Czar of Russia—a fact which the Czars of Russia have persisted till lately in bringing forward as a claim in favor of their pretensions to the possession of European Turkey. It is said that direct descendants of the Palæologi exist to the present day in France. (For further information, see the separate articles on some of the emperors, and BYZANTINE EMPIRE.)

PALÆONISCUS (Gr. ancient sea-fish), a genus of ganoid fish, with a fusiform body, covered with rhomboid scales, a heterocercal tail, and moderately-sized fins, each furnished with an an-

Palæoniscus.

terior spine. The single dorsal fin is opposite to the interval between the anal and ventral fins. Twenty-eight species have been described from the Carboniferous and Permian measures.

PALÆONTOLOGY (Gr. science of fossil animals) is that division of Geology (q. v.) whose province it is to inquire into the evidence of organic life on the globe during the different bygone geological periods, whether this evidence arises from the actual remains of the different plants and animals, or from recognizable records of their existence, such as footprints, Coprolites, (q. v.), &c.

The metamorphic action which has so remarkably altered the oldest sedimentary rocks, is sufficient to have obliterated all traces of organic remains contained in them. Fossils are consequently extremely rare in these older palæozoic strata, and indeed it is only after long search, and within a recent time, that undoubted remains have been found in the Laurentian rocks. We were unable to record their existence in the article LAURENTIAN SYSTEM; but in the article LIMESTONE, we referred to the existence of beds of limestone as requiring the presence of animal life for their production. It is true that in 1852 an organic form resembling a coral was found in the limestone of the Ottawa, but much doubt was always entertained regarding this solitary discovery.

In 1863, however, there was detected an organism in the serpentine limestone of Grenville, of true Laurentian age, which Dr. Dawson describes as that of a Foraminifer, growing in large sessile patches, after the manner of *Carpentaria*, but of much greater dimensions, and presenting minute points which reveal a structure resembling that of other foraminiferal forms, as for example, *Calcarina* and *Nummulina*. Large portions of the limestone appear to be made up of these organisms, mixed with other fragments, which suggest comparisons with crinoids and other calcareous fossils, but which have not yet been distinctly determined. Some of the limestones are more or less colored by carbonaceous matter, exhibiting evidences of organic structure, probably vegetable. In this single Foraminifer, and the supposed coral, we have all that is positively known of the earliest inhabitants of our globe, with which we are yet acquainted. That these are but the smallest fraction of the fauna of the period in which they lived, is evident from the undetermined fragments associated with them, as well as from the extensive deposits of limestone of the same age. And that contemporaneous with them, there existed equally numerous representatives of the vegetable kingdom, cannot be doubted, when it is remembered that the animal can obtain its food only through the vegetable, and not directly from inorganic materials. Besides, their remains apparently exist in the limestone at Grenville, a rock which, from its very nature, rarely contains vegetable fossils.

The Cambrian rocks, though of immense thickness, have hitherto yielded indications of only a very few animals, but these have a special interest, as they are the oldest fossil remains yet detected in Britain. They consist of an impression which Salter considers to be portion of a trilobite, named by him *Palæopyge*, of the burrows and tracks of sea-worms, and of two species of radiated zoophytes called *Oldhamia*—animals which in this case also can be nothing more than the most fragmentary representations of the fauna of the period. No indications of vegetable life have yet been noticed in the Cambrian rocks, for we cannot consider the superficial marking on some of these strata as having anything to do with fungi.

Undoubted representations of the four invertebrate sub-kingdoms early make their appearance in the Silurian strata, and the occurrence before the close of the period of several fish, adds to them the remaining sub-kingdom—the vertebrata. If we except the silicious frustules of Diatomacea which are said to have been detected in these rocks, no satisfactory traces of plants have yet been observed, although extensive layers of anthracitic shales are common. Of the lower forms of the animal kingdom, some sponge-like bodies have been found, and corals are remarkably abundant, chiefly belonging to the order *Rugosa*, a palæozoic type, the members of which have horizontal tabulæ, and vertical plates or septa, either four in number, or a multiple of four. Graptolites, another family of zoophytes, flourished in the dark mud of the Silurian seas, and did not survive the period.

All the great divisions of the Mollusca are represented by numerous genera, several of which are not very different from some living forms. A few true star-fishes have left their records on the rocks, but the most striking feature in the Echinodermata of the period is the Cystideans, or armless sea-lilies, which, like the Graptolites, did not pass beyond the Silurian seas. Tubes, tracks, and burrows of annelids have been observed; and numerous Crustacea, belonging, with the exception of one or two shrimp-like species, to the characteristic palæozoic Trilobite, of which the number of individuals is as remarkable as the variety of species and genera. It is only in the upper portion of the group (the Ludlow beds) that the fish remains have been found. These have been referred to six different genera, and are chiefly loricate ganoids, of which *Cephalspis* is the best known.

The rocks of the Old Red Sandstone period supply the earliest satisfactory remains of plants. The Ferns, Sigillarie, Lycopodites, and Calamites, so abundant in the Coal Measures, make

their appearance among the newer of these beds, and even fragments of dicotyledonous wood have been observed. The various sections of the invertebrata are well represented, but the remarkable characteristic in the animal life of the period is the abundance of strange forms of heterocercal-tailed fish, whose buckler-shields, hard scales, or bony spines occur in the greatest abundance in some beds. The reptiles and reptile tracks in the Red Sandstone of Moray, originally referred here, are now universally considered as belonging to the New Red measures.

The striking feature in the rocks of the Carboniferous period is the great abundance of plants, the remains of which occur throughout the whole series, the coal-beds being composed entirely of them, the shales being largely charged with them, the sand-stones containing a few, and even the limestones not being entirely without them. These plants were specially fitted for preservation, the bulk of them being vascular cryptogams, a class which Lindley and Hutton have shown by experiment to be capable of long preservation under water. They are chiefly ferns; some are supposed to have been arborescent lycopods, while others (*Sigillaria*, *Calamites*, and *Asterophyllites*) are so different from anything now known, that their position cannot be definitely determined, though it is most probably among the higher cryptogams. Several genera of conifers have been established from fossilized fragments of wood; and some singular impressions, which look like the flowering stems of dicotyledonous plants, have been found. The limestones are chiefly composed of crinoids, corals, and brachiopodous shells. The corals attain a great size, and the crinoids are extremely abundant, their remains making sometimes beds of limestone 1000 feet thick, and hundreds of square miles in extent. Many new genera of shells make their appearance. The trilobites, which were so abundant in the earlier rocks, are reduced to one or two genera, and finally disappear with this period.

Fish with polished bony scales are found; and others, like the Port Jackson skark, with pavements of flat teeth over their mouth and gullet, fitting them to crush and grind the shell-protected animals on which they fed. Strange fish-like reptiles existed in the seas, and air-breathing species have been found on the continent and in America. The wing-cases, and parts of the bodies of insects, have also been found.

The Permian period is remarkable for the paucity of its organic remains, but this may arise from our comparative ignorance of its strata. The plants and animals are on the whole similar to those found in the Carboniferous measures, and a great proportion of them belong to the same genera. Many ancient forms do not pass this period, as the *Sigillaria* among plants, and the *Producta* among animals.

The red sandstones of the Triassic period are remarkably destitute of organic remains—the iron, which has given to them this color, seems to have been fatal to animal life. In beds, however, on the continent, in which the iron is absent, fossils abound. These fossils present a singular contrast to those met with in the older rocks. The Palæozoic forms have been gradually dying out, and the few that were still found in the Permian strata do not survive that period, while in their place there appear in the Trias many genera which approach more nearly to the living forms. Between the organisms of the Permian and Triassic periods there exist a more striking difference than is to be found between those of any previous periods. Looking at this life-character, the rocks from the Permian downwards have been grouped together under the title Palæozoic; while from the Trias upwards the whole of the strata have received the name of Neozoic.

The extensive genera of Ammonites and Belemnites make their first appearance in the Trias. Several new forms of Cestraciant fish occur, and the reptiles increase in number and variety; among them is the huge batrachian Labyrinthodont, and the singular fresh-water tortoise, *Dicynodon*. The bird-tracks on the sandstones of Connecticut are by some referred to this age. Small teeth of mammalia, believed to be those of an insectivorous animal, like the *Myrmecobius* of Australia, have been found in the Keuper beds of Germany and Somerset.

In the Oolitic series we have an abundance of organic remains, in striking contrast to the scanty traces in the Permian and Triassic periods. Many new genera of ferns take the place of the Palæozoic forms, and a considerable variety of Conifers make their appearance, some of which have close affinities with living species, one, indeed, being referred to a still existing genus. The same approximation to living types is to be found in the animal kingdom. Several of the foraminifers are referred to living genera. Among the corals, the representatives of two living families make their appearance. No new genera are found among the Brachiopoda; but the Conchifera and Gasteropoda show a great addition of new genera, some of which are still represented by living species, while not many new genera were added to the Cephalopoda, though they were individually very abundant. In some places the Lias shale consists of extensive pavements of Belemnites and Ammonites. The Crinoids give place to the increasing variety of sea-urchins and star-fishes. Numbers of insects have been found.

The Cestraciant continue to be represented in the Oolitic seas, but with them are associated several true sharks and rays; and the homocercal-tailed fish become numerous. Labyrinthodont reptiles abound: the huge Megalosaur and its companions occupied the land; while the seas were tenanted with the remarkable Ichthyosaur and Plesiosaur, and the air with the immense bat-like Pterodactyle. Seven genera of Mammalia have been found, all believed to be small carnivorous or insectivorous marsupials, except the Stereognathus, which Owen considers to have been a placental mammal, probably hoofed and herbivorous.

In the Cretaceous beds, which are chiefly deep-sea deposits, the remains of plants and land animals are comparatively rare. The Wealden beds, however, which had a fresh-water origin, contain the remains of several small marsupials, some huge carnivorous and herbivorous reptiles, a few fresh-water shells, and some fragments of drift-wood. The true chalk is remarkably abundant in the remains of foraminifers—indeed, in some places, it is composed almost entirely of the shells of these minute creatures. Of the mollusca, the Brachiopoda are in some beds very abundant; the Conchifera introduce several new forms, the most striking of which is the genus Hippurites, which with its allies did not survive this period; the cephalopodous genera which appeared in the Oolite, continue to abound in the chalk, many new forms being introduced; while others disappear with the period, like the Belemnites and Ammonites. Sea-urchins become still more numerous.

In some of the beds the remains of fish are abundant, and while cartilaginous species still exist, the bony fishes become more numerous; and among them the family to which the salmon and cod belong makes its appearance. Reptiles are common in the Wealden, and the flying Pterodactyles attained a greater size, and were probably more numerous than in the former period. The remains of a single bird has been obtained from the greensand, but with this exception, birds as well as mammals have left no traces that have yet been found in the Cretaceous beds, though doubtless they existed.

In the Tertiary strata, the genera are either those still living, or forms very closely allied to them, which can be separated only by the careful examination of the accurate scientific observer. The plants of the Eocene beds are represented by dicotyledonous leaves, and palm and other fruits. Foraminifers are remarkably abundant, whole mountain masses being formed of the large genus Nummulites. Brachiopoda are rare, but Conchifera, Gasteropoda, and Cephalopoda increase in number; the new forms being generically almost identical with those now living. The principal living orders of fish, reptiles, and birds are represented in the Eocene strata. A considerable variety of pachydermatous mammals, suited apparently to live on marshy grounds and the borders of lakes, have been found in France and England, and associated with them are some carnivorous animals, whose remains are, however, much rarer. An opossum has been found at Colchester. The fragments belonging to the supposed monkey are portions of a small pachyderm, *Hyracotherium* (q. v.).

Little need be said of the invertebrata of the Miocene period, beyond remarking their growing identity in genera with the living forms. Among the mammals, the *Quadrumana* make their first appearance. The true elephant and the allied mastodon are represented by several species; a huge carnivorous whale has been discovered, and several Carnivora and deer, with a huge edentate animal, have been described. Owen thus speaks of these animals: 'Our knowledge of the progression of Mammalian life during the Miocene period, teaches us that one or two of the generic forms most frequent in the older Tertiary strata still lingered on the earth, but that the rest of the Eocene Mammalia had been superseded by new forms, some of which present characters intermediate between those of Eocene and those of Pliocene genera.'

In passing upwards through the Tertiary strata, the organic remains became more and more identical with living forms, so that when we reach the Pliocene and Pleistocene periods, the great proportion of the invertebrata are the same species which are found occupying the present seas. Among the higher orders of animals, the life of a species is much shorter than in the lower, and consequently, though the vertebrata approach so nearly to existing forms as for the most part to be placed in the same genera, yet the species differ from any of the living representatives of the different genera.

The Suffolk 'Crags,' which are the only British representatives of the Pliocene period, contain the relics of a marine testacea, that differs little from the present tenants of the European seas, between 60 and 70 per cent. being the same species. The ear-bones of one or more species of Cetacea have been found, and at Antwerp, the remains of a dolphin have been discovered in beds of this age.

The various local deposits which together form the Pleistocene strata, the latest of the geological periods, contain a great variety of organic remains. In the submarine forests, and in beds of

peat, the stumps of trees are associated with the remains of underwood and herbaceous plants of species still living. Nearly all the mollusca and other marine invertebrata still survive. It is among the vertebrata that the most remarkable forms appear—forms which in the main differ little from the existing race of animals except in their enormous size. Elephants and rhinoceroses, fitted for a cold climate by their covering of long coarse hair and wool, roamed over the northern regions of both the Old and the New World, and were associated with animals belonging to genera which still exist in the same region, as bears, deer, wolves, foxes, badgers, otters, wolverines, weasels, and beavers, besides others whose representatives are now found further south, as the hippopotamus, tapir, and hyena. Contemporary with these, there lived in South America a group of animals which were types in everything but in size of the peculiar existing fauna of that continent. Among these were gigantic sloth-like animals, fitted to root up and push down the trees, instead of climbing to strip them of their foliage, like the sloth. The armadillo was represented by the huge Glyptodon, whose body was protected by a strong tessellated coat of mail. The species of fossil tapirs and peccaries are more numerous than their living representatives.

The lamas were preceded by the large Macrauchenia, and the opossums and platyrrhine monkeys were also prefigured by related species. Besides these, there have been found the remains of two mastodons and a horse, none of which are represented by any indigenous living animal in South America. The peculiar group of animals confined to Australia were prefigured by huge marsupials, some having close analogies to the living kangaroos and wombats, while others were related to the carnivorous native tiger. The gigantic wingless birds of New Zealand correspond in type with the anomalous apteryx, now existing only on these islands.

Associated with the remains of elephants, mastodons, cave-bears, and cave-hyenas, there have been found, in England and France, numerous specimens of flint implements, which are undoubtedly the result of human workmanship, and show at least that man was contemporaneous with these extinct animals. If more certain evidence were needed of this, it has been obtained in the discovery of flint implements, bone implements fashioned and carved by means of the flint knives, the horns of a reindeer, two kinds of extinct deer, *Bos primigenius*, and other animals, associated with numerous bones of man, included in the breccia of the cave of Bruniquet in France. Owen considers the evidence of the contemporaneity of the various remains as conclusive. The several human skulls which have been obtained show, according to the same authority, no characters whatever indicative of an inferior or transitional type. There are no certain data to give probability to the guesses which have been made as to the number of years which have elapsed since these deposits in which the relics of man occur were formed. The whole inquiry, is so recent, and the accumulation of facts is almost every day going on, that it would be premature to speak dogmatically on the subject.

PALÆOPYGÉ (Gr. ancient rump), a genus fossil Crustacea, founded on a single impression from the surface of a bed in the Longmynd, of Cambrian age. Salter believes it to be the cephalic shield of a trilobite, but it may be only an accidental marking. If it be the impression of an organism, it is so distorted and imperfect that little can be made of it; its petular interest arises from its being associated with the earliest forms of life that have been observed on the globe.

PALÆOSAURUS (Gr. ancient lizard), a genus of fossil saurian reptiles peculiar to the Permian period. The remains of two species occur in the dolomitic conglomerate at Redland, near Bristol. The teeth were more or less compressed, and were furnished with serrated cutting margins. The vertebræ were biconcave, and had a remarkable depression in the center of each vertebræ, into which the spinal canal was sunk. The leg-bones show that the Palæosaurs were fitted for moving on the land. Owen thus exhibits their affinities: 'In their thecodont type of dentition, biconcave vertebræ, double-jointed ribs, and proportionate size of the bones of the extremities, they are allied to the Telesaurus, but with these they combine a Dinosaurian femur, a lacertian form of tooth, and a crocodilian structure of pectoral and probably pelvic arch.'

PALÆOTHEURIUM (Gr. ancient wild beast), a genus of pachydermatous mammalia whose remains occur in the Eocene beds of England and the continent. At least ten species have been described, ranging in size from that of a sheep to that of a horse. The upper Eocene gypseous quarries of Montmartre supplied the first scanty materials, which Cuvier, by a series of careful and instructive inductions,

Palæotherium.

built up into an animal, whose fidelity to nature was afterwards

verified by the discovery of a complete series of fossils. In general appearance the Palæotherium resembled the modern tapir, and especially in having the snout terminating in a short proboscis. It had three toes on each foot, each terminated by a hoof.—The formula of the teeth is the same as that of the Hyrachthera, viz.,

$$I. \begin{array}{c} 3-3 \\ 3-3 \end{array}, C. \begin{array}{c} 1-1 \\ 1-1 \end{array}, P.M. \begin{array}{c} 4-4 \\ 4-4 \end{array}, M. \begin{array}{c} 3-3 \\ 3-3 \end{array} = 44;$$

but the structure of the molar approaches nearer to the molars of the rhinoceros. It is supposed that animals of this genus dwelt on the margins of lakes and rivers, and that their habits were similar to those of the tapir.

PALÆOZOÏC (Gr. ancient life), the name given to the lowest division of fossiliferous rocks, because they contain the earliest forms of life. They were formerly, and are still generally, known as the Primary rocks. The strata included under these titles are the Laurentian, Cambrian, Silurian, Old Red Sandstone, Carboniferous, and Permian systems. Phillips, for the sake of uniformity, introduced Mesozoic as equivalent to Secondary, and Neozoic to Tertiary rocks.

PALÆSTRA, a building for gymnastic sports.

PALAFIX Y MELZI, DON JOSE DE, Duke of Saragossa, a Spanish patriot, was born in 1780 of a distinguished Aragonese family, and received an excellent education. He accompanied Ferdinand VII. to Bayonne, and on seeing him made a prisoner there, fled to Saragossa, where he exerted himself to prevent the invasion of Aragon by the French. His defence of Saragossa (q. v.) 27th July 1808—21st February 1809, which only yielded to the French after a second investment, is one of the most brilliant and heroic incidents in modern history, and has conferred lasting glory on P. and the whole city. The ancient fame of the Spaniards for obstinate valor in the defence of walled cities was rivalled, if not surpassed, and Saragossa could proudly claim to vie with Numantia. P., sick and exhausted, was taken prisoner and conveyed by the ungenerous French to the dungeons of Vincennes, where he was treated with great hardship. Released in 1813, he returned to Spain, and was appointed in the following year captain-general of Aragon. P. was no great politician, but he loved liberty and hated anarchy, and on more than one occasion he supported the former and crushed the latter. After being created Duke of Saragossa, and Grandee of Spain of the first class in 1836, he kept himself apart from politics. He died at Madrid, 16th February 1847.

PALAIS ROYAL, a heterogeneous mass of buildings on the eastern side of the Rue Richelieu in Paris, composed of a palace, theaters, public gardens, bazaars, shops, cafés, and restaurants. The old palace was built between 1624 and 1636 on the site of the Hôtel Rambouillet by Cardinal Richelieu, who at his death bequeathed it to Louis XIII. Henrietta of France, widow of Charles I., and Anne of Austria, the queen mother, afterwards lived in it for a time with her young son, Louis XIV. It subsequently became the town residence of the Orleans branch of the Bourbons, and during the minority of Louis XV. it acquired a scandalous notoriety as the scene of the wild orgies in which the regent, Duke of Orleans, and his dissolute partisans were wont to indulge; while in the time of his son, Philippe Egalité, it became the focus of revolutionary intrigue, and the rendezvous for political demagogues of every shade of opinion. This prince, partly to repair his impoverished fortune, and partly to persuade the sans-culottes of Paris of the sincerity of his professed sympathy with their striving for equality, converted part of his gardens into a place of public resort, and the pavilions of the great court into bazaars, which were divided into shops and stalls. On the downfall of Egalité, the P. R. was taken possession of by the republican government, and used for the sittings of the tribunes during the Reign of Terror.

On the restoration of the Bourbons, it reverted to the Orleans family, and was occupied by Louis Philippe till his election to the throne of France in 1830, when it was incorporated in the general domains of the state, and ceased to be an appanage of the House of Orleans. The palace was sacked by the mob during the Revolution of 1848, when many of its best paintings and most precious works of art were destroyed. After having been temporarily appropriated to various public purposes, it was thoroughly repaired and magnificently furnished, and given by the late emperor, in 1855, to his uncle Jerome Bonaparte, whose son Prince Napoleon, resided there until 1871. The main entrance, with its elegant façade, is in the Rue St. Honoré; and on passing through the first court, the second or Cour Royale is reached, to the left of which stands the Théâtre Français, while immediately facing it is the celebrated Galerie Vitrière, or Glass Gallery, which contains on the ground floor some of the most brilliant shops of Paris, while the upper stories are chiefly occupied by cafés and restaurants. The garden, which is surrounded by this and other galleries, measures 700 feet by 300. The Red Republicans set fire

to the palace in March 1871 (see PARIS), when all the apartments occupied by Prince Napoleon were destroyed. The firemen and those who aided them, while forming into line to pass buckets of water, were fired upon by the insurgents; but kept to their work, and succeeded in checking the flames before they spread to the galleries and shops, which may almost be said to have remained intact.

In the autumn of 1873 that part of the palace injured by the insurgents was restored. The garden with its avenues and parterres, fountains and grass plots, still constitutes one of the liveliest and most frequented spots in the whole city; and although much of their glory has faded, its cafés still maintain, in great measure, the world-wide reputation they long ago acquired.

PALANQUIN, or **PALKI**, the vehicle commonly used in Hindustan by travelers, is a wooden box, about 8 feet long, 4 feet wide, and 4 feet high, with wooden shutters which can be opened or shut at pleasure, and constructed like Venetian blinds for the purpose of admitting fresh air while at the same time they exclude the scorching rays of the sun, and the heavy showers of rain so common in that country. The furniture of the interior consists of a cocoa mattress, well stuffed and covered with morocco leather, on which the traveler reclines; two small bolsters are placed under his head, and one under his thighs, to render his position as comfortable as possible. At the upper end is a shelf and drawer, and at the sides are nettings of larger dimensions than the ordinary nettings in carriages, for containing those articles which may be necessary to the traveler during his journey. At each end of the palanquin, on the outside, two iron rings are fixed, and the *hammala*, or palanquin-bearers, of whom there are four, two at each end, support the palanquin by a pole passing through these rings. Traveling in this mode is continued both by day and night. (See *DAWK.*) The palanquin is also used at the present day in Brazil, with the prominent exception of Rio Janeiro.

Similar modes of traveling have been at various times in use in Western Europe, but only for short distances. The Roman 'litter,' the French 'chaise a porteurs,' and the 'sedan-chair' were the forms of vehicle most in use, and the two latter were in general use in towns till they were superseded by hackney coaches. The Roman 'litter' was one of the criteria of its owner's wealth, the rich man generally exhibiting the prosperous condition of his affairs by the multitude of the bearers and other attendants accompanying him.

PALAPTERYX (Gr. ancient apteryx), a genus of fossil birds whose remains are found in the river-silt deposits of New Zealand, associated with the gigantic *Dinornis*, and which, like it, resembled in the form of the sternum, and the structure of the pelvis and legs, the living wingless apteryx. Two species have been described.

PALATE, **THE**, forms the roof of the mouth, and consists of two portions, the hard palate in front and the soft palate behind. The framework of the *hard palate* is formed by the palate process of the superior maxillary bone, and by the horizontal process of the palate bone, and is bounded in front and at the sides by the alveolar arches and gums, and posteriorly it is continuous with the soft palate. It is covered by a dense structure formed by the periosteum and mucous membrane of the mouth, which are closely adherent. Along the middle line is a linear ridge or raphe, on either side of which the mucous membrane is thick, pale, and corrugated, while behind it is thin, of a darker tint, and smooth. This membrane is covered with scaly epithelium, and is furnished with numerous follicles (the palatal glands). The *soft palate* is a movable fold of mucous membrane enclosing muscular fibres, and suspended from the posterior border of the hard palate so to form an incomplete septum between the mouth and the pharynx; its sides being blended with the pharynx, while its lower border is free. When occupying its usual position (that is to say, when the muscular fibres contained in it are relaxed), its anterior surface is concave; and when its muscles are called into action, as in swallowing a morsel of food, it is raised and made tense, and the food is thus prevented from passing into the posterior nares, and is at the same time directed obliquely backwards and downwards into the pharynx.

Hanging from the middle of its lower border is a small conical pendulous process, the *uvula*; and passing outwards from the uvula on each side are two curved folds of mucous membrane containing muscular fibres, and called the *arches* or *pillars* of the *soft palate*. The *anterior pillar* is continued downwards to the side of the base of the tongue, and is formed by the projection of the palato-glossus muscle. The *posterior pillar* is larger than the anterior, and runs downwards and backwards to the side of the pharynx. The anterior and posterior pillars are closely united above, but are separated below by an angular interval, in which the *tonsil* of either side is lodged. The tonsils (*amygdalæ*) are glandular organs of a rounded form, which vary considerably in size in different individuals. They are composed of an assem-

blage of mucous follicles, which secrete a thick grayish matter, and open on the surface of the gland by numerous (12 to 15) orifices.

The space left between the arches of the palate on the two sides

The Mouth widely opened so as to show the Palate:

1, 1, the upper, and 2, the lower lip; 3, 3, the hard palate; 4, 4, the soft palate; 5, the uvula; 6, 6, the arches of the soft palate; 7, 7, the tonsils; 8, the tongue.

is called the *isthmus of the fauces*. It is bounded above by the free margin of the palate, below by the tongue, and on each side by the pillars of the soft palate and tonsils.

As the upper lip may be fissured through imperfect development (in which case it presents the condition known as hare-lip), so also may there be more or less decided fissure of the palate. In the slightest form of this affection, the uvula merely is fissured, while in extreme cases the cleft extends through both the soft and hard palate as far forward as the lips, and is then often combined with hare-lip. When the fissure is considerable, it materially interferes with the acts of sucking and swallowing, and the infant runs a great risk of being starved; and if the child grows up, its articulation is painfully indistinct. When the fissure is confined to the soft palate, repeated canterization of the angle of the fissure has been found sufficient to effect a cure by means of the contraction that follows each burn. As a general rule, however, the child is allowed to reach the age of puberty when the operation of *staphyloraphy* (or suture of the soft parts) is performed—an operation always difficult, and not always successful. For the method of performing it, the reader is referred to the *Practical Surgery* of Mr. Fergusson, who has introduced several most important modifications into the old operation.

Acute inflammation of the tonsils, popularly known as **QUINSY**, is treated of in a separate article.

Chronic enlargement of the tonsils is very frequent in scrofulous children, and is not rare in scrofulous persons of more advanced age, and may give rise to very considerable inconvenience and distress. It may occasion difficulty in swallowing, confused and inarticulate speech, deafness in various degrees from closure of the eustachian tubes (now often termed *throat deafness*), and noisy and laborious respiration, especially during sleep; and it may even cause death by suffocation, induced by the entanglement of viscid mucus between the enlarged glands. Iodide of iron (especially in the form of *Blancard's Pills*) and cod-liver oil are the medicines upon whose action most reliance should be placed in these cases, while a strong solution of nitrate of silver (a scruple of the salt to an ounce of distilled water), or some preparation of iodine, should be applied once a day to the affected parts. If these measures fail, the tonsils must be more or less removed by the surgeon, either by the knife or scissors, or by a small *guillotine* specially invented for the purpose.

Enlargement or relaxation of the uvula is not uncommon and gives rise to a constant tickling cough, and to expectoration, by the irritation of the larynx which it occasions. If it will not yield to astringent or stimulating gargles, or to the stronger local applications directed for enlarged tonsils, its extremity must be seized with the forceps, and it must be divided through the middle with a pair of long scissors.

PALA'TINATE, a name applied to two German states, which were united previously to the year 1620. They were distinguished as the Upper and Lower Palatinate. The Upper or Bavaria P., now forming a circle of the kingdom of Bavaria, was a duchy, and was bounded by Baireuth, Bohemia, Neuburg, Bavaria, and the district of Nürnberg. Area, 2780 square miles; pop. (1807) 283,800. Amberg was the chief city, and the seat of government. The Lower P., or the Palatinate on the Rhine, embraced an area of from 3045 to 3150 square miles; and consisted of the electoral P., the principality of Simmern, the duchy of Zweibrücken, the half of the county of Sponheim, and the principalities of Beldenz and Lautern. For the area and population of the modern provinces of the Upper and Lower P., see article **BAVARIA**.

The counts of the electoral or Rhenish P. were established in the hereditary possession of the territory of that name, and of the lands attached to it, as early as the 11th century. After the death of Herman III., the Emperor Friedrich I. assigned the P. to Conrad of Swabia. After Conrad's death, his son-in-law, Duke Henry of Brunswick, came, in 1196, into the possession of these lands, but he, having been outlawed in 1215 by Friedrich II., was succeeded by his son, Otto III., Duke of Bavaria. Ludwig II., or the Strong, succeeded the preceding in the P. in 1253, and was in turn succeeded in 1294 by Rudolf I., who, however, was banished by his brother, the Emperor Ludwig, because he had taken part with Friedrich of Austria. The country was ruled by his three sons.

Ruprecht III., who died in 1410, was a German emperor. Of his four sons, Ludwig III. received the electoral or Rhenish P.; Johann, the Upper P.; Stephan, Zweibrücken; and Otto, Mosbach. The second and fourth lines soon died out, as well as also that of Ludwig III., which came to a close in 1559, upon which the possessions of that prince, together with the electorate, passed to Friedrich III. of the Simmern line. He was succeeded by Ludwig IV. in 1576, by Friedrich IV. in 1583, and by Friedrich V. in 1610, who, after he accepted the Bohemian crown, was driven from his possessions by the emperor in 1619, and his office of elector was transferred to Maximilian, Duke of Bavaria. Karl Ludwig, son of Friedrich V., received the Lower P. at the peace of Westphalia, and in his favor a new or eighth electorate was created. With his son Karl, the Simmern line terminated in 1685, upon which the P. fell into the hands of Philipp Wilhelm, count palatine of Neuburg.

The House of Neuburg was descended from Ludwig the Black, count palatine in Zweibrücken, second son of Stephan, count palatine in Simmern. Wolfgang, a descendant of Ludwig's, was the founder of all the other lines of counts palatine. Of his three sons, Johann founded the line of Neu-Zweibrücken, Karl the Birkenfeld line, Philipp Ludwig the Neuburg line. Philipp Ludwig had three sons, Wolfgang Wilhelm, August, and Johann Friedrich. The first founded the Neuburg line, the second the Sulzbach line, the third died childless. The son of Wolfgang Wilhelm died in 1690. His son, Johann Wilhelm, became heir to the Beldenz line in 1694. He was succeeded by his brother, Karl Philipp, who in turn was succeeded in 1742 by Karl Theodor, from the Sulzbach line, who united the Bavarian territories with the Palatinate. Duke Maximilian of Zweibrücken next succeeded in 1799, who at the peace of Lunéville (1801) was compelled to cede a portion of the Rhenish P. to France, a part to Baden, a part to Hesse-Darmstadt, and a part to Nassau. Treaties of Paris of 1814 and 1815 re-assigned the Palatinate lands beyond the Rhine to Germany, Bavaria receiving the largest share, and the remainder being divided between Hesse-Darmstadt and Prussia.

PA'LATINE (from Lat. *palatium*, a palace). A *Comes Palatinus*, or Count Palatine, was under the Merovingian kings of France, a high judicial officer, who had supreme authority in all causes that came under the immediate cognizance of the sovereign. After the time of Charlemagne, a similar title was given to any powerful feudal lord, to whom a province, generally near the frontier, was made over with *jura regalia*, or judicial powers, similar to what the counts palatine had received in the palace, and the district so governed was called a *palatinate* or *county palatine*. There were three counties palatine in England—Lancaster, Chester, and Durham—which were, no doubt, made separate regalities on account of their respective proximity to the frontier of Wales and to that turbulent Northumbrian province which could neither be accounted a portion of England nor of Scotland. In virtue of their regal rights, the counts palatine had their courts of law, appointed their judges and law officers, and could pardon treasons, murders, and felonies; all writs and judicial process proceeded in their names, and the king's writs were of no avail within the bounds of the palatinate. Lancaster seems to have been made a county palatine by Edward III. Henry, first Duke, and John, second Duke of Lancaster, were both invested by him with the dignity of count palatine.

Henry VI. was hereditarily Duke and Count Palatine of Lancaster, and on his attainder, soon after Edward IV.'s accession, the

duchy and county were forfeited to the crown, and confirmed on Edward IV.—afterwards on Henry VII. and his heirs for ever. The Queen is now Duchess and Countess Palatine of Lancaster. There is still a chancellor of the duchy and county palatine, whose duties are few and unimportant, but the administration of justice has gradually been assimilated to that of the rest of England. See **LANCASTER**. Chester is supposed to have become a county palatine when made over with regal jurisdiction by William the Conqueror to Hugues d'Avranches. In the reign of Henry III. it was annexed to the crown by letters patent, and since that time the earldom palatine of Chester has been vested in the eldest son of the sovereign, or in the crown, whenever there is no Prince of Wales. Durham seems to have first become a palatinate when William the Conqueror constituted Bishop Walcher Bishop and Duke of Durham, with power (according to William of Malmesbury) to restrain the rebellious people with the sword, and to reform their morals with his eloquence.

The Palatinate jurisdiction continued united with the bishopric till 1836, when it was separated by act of parliament, and vested in William IV. and his successors as a franchise distinct from the crown, together with all forfeitures, mines, and *jura regalia*. It has since been more completely incorporated with the crown. Pembroke was at one time a county palatine, but ceased to be so in Henry VIII.'s time. The Archbishop of York also exercised the powers of a palatine in the county of Hexham in Northumberland, of which he was deprived in the reign of Elizabeth. In very early times there were a number of similar privileges in Scotland, the most important of which was that of the Earls Palatine of Strathern. In Germany, the *Pfalzgraf*, or count palatine, exercised a jurisdiction much more extensive than the simple *graf* or count. A considerable district in Germany was long under the jurisdiction of a count palatine, who was one of the electors of the empire. See **PALATINATE**.

PALATINE HILL (*Mons Palatinus*), the central hill of the famous seven on which ancient Rome was built, and, according to tradition, the seat of the earliest Roman settlements. In point of historical interest, it ranks next to the Capitol and the Forum. Its summit is about 160 feet above the sea. The form of the hill is irregularly quadrangular. Its north-western slope, towards the Capitoline Hill and the Tiber, was called *Germalus* or *Cermalus*. The origin of the name is uncertain, although several derivations are given connecting it with legendary stories. Romulus is said to have founded the city upon this hill, and on Germalus grew the sacred fig-tree (near to the Lupercal) under which he and his brother, Remus, were found sucking the she-wolf. Upon the P. H. were the temple of Jupiter *Stator*, the temple of Cybele, the sacred square enclosure called *Roma Quadrata*, and other sacred places and edifices, besides many of the finest houses in Rome. Augustus and Tiberius had their residences here, whence Tacitus termed it *ipsa imperii ara* (the very citadel of government); and at last Nero included it entirely within the precincts of his *auræa domus*, which Vespasian subsequently restricted to the hill. From the time of Alexander Severus it ceased to be the residence of the emperors, but the name *palace* (*palatium*), derived from it, was given to the abodes of sovereigns and great princes, and has been adopted into modern languages. Recent excavations have brought to light numerous remains of the palatial and other structures with which the P. H. was once covered; and these are now among the most interesting sights of the eternal city.

PALAWA'N, or **PARAGOA**, one of the Philippine Islands (q. v.).

PALAY (*Cryptostegia grandiflora*), a climbing plant of the natural order *Asclepiadaceæ* (q. v.), common in many parts of India, particularly on the eastern coast of Hindustan. It yields a very fine strong white fibre, resembling flax, and which can be spun into the finest yarn. The fibre is obtained from the stalk; the milky juice contains caoutchouc. P. is one of the most interesting plants which have recently been recommended to notice in India.

PALA'ZZOLO ACREI'DE, a town of Sicily, in the province of Syracuse, 29 miles south-south-west of Catania, is situated on the brow of a hill, just where it overhangs a deep valley. Near P. are the remains of the ancient *Acra*, founded by a colony from Syracuse, on the site of a Phœnician settlement, 664 B.C. The most curious remains are to be found in some low cliffs beneath the town to the south, where is a series of arched niches, containing figures carved in high relief in the rock. The style of art appears to be archaic Greek, with somewhat of an Egyptian character. Pop. 9954.

PALE, in Heraldry, one of the figures known as ordinaries, consisting of a perpendicular band in the middle of the shield, of which it is said to occupy one third (No. 1). Several charges of any kind are said to be 'in pale' when they stand over each other perpendicularly, as do the three lions of England. A shield divided through the middle by a perpendicular line is said

to be 'parted per pale.' The Pallet is the diminutive of the pale, and is most generally not borne singly. No. 2, Or three pallets gules, were the arms of Raymond, Count of Provence. When the field is divided into an even number of parts by per-

pendicular lines, it is called 'paly of' so many pieces, as in No. 3, Paly of six argents and gules, the arms of the family of Ruthven. When divided by lines perpendicular and bendways crossing, it is called paly bendy, as in No 4. An Endorse is a further diminutive of the pallet, and a pale placed between two endorses is said to be endorsed (No. 5).

PALE, in Irish history (see IRELAND, HISTORY), means that portion of the kingdom over which the English rule and English law was acknowledged. There is so much vagueness in the meaning of the term, that a few words of explanation appear necessary. The vagueness arises from the great fluctuations which the English authority underwent in Ireland at various periods, and from the consequent fluctuation of the actual territorial limits of the Pale. The designation dates from the reign of John, who distributed the portion of Ireland then nominally subject to England into twelve counties palatine, Dublin, Meath, Kildare, Louth, Carlow, Kilkenny, Wexford, Waterford, Cork, Kerry, Tipperary, and Limerick. To this entire district, in a general way, was afterwards given the designation of the Pale. But as it may be said that the term is commonly applied by the writers of each age to the actual English territory of the period, and as this varied very much, care must be taken to allude to the age of which the name Pale is used. Thus, very soon after the important date of the Statute of Kilkenny, at the close of the reign of Edward III., the English law extended only to the four counties of Dublin, Carlow, Meath, and Louth. In the reign of Henry VI., the limits were still further restricted. In a general way, however, the Pale may be considered as comprising the counties of Dublin, Meath, Carlow, Kilkenny, and Louth. This, although not quite exact, will be sufficient for most purposes.

PA'LEA (Lat. chaff), a term employed in Botany to designate the bracts of the *florets* in Grasses (q. v.), called *corolla* by the older botanists; also to designate the small bracts or scales which are attached to the receptacle of the head of flowers in many of the *Compositæ* (q. v.). Any part of a plant covered with chaffy scales is described as *paleaceous*.

PALEMBA'NG, formerly an independent kingdom on the east coast of Sumatra, now a Netherlands residency, is bounded on the N. by Djambi, N.W. by Bencoolen, S. by the Lampong districts, and S.E. by the Strait of Banca, has an area of 61,900 square miles; and a population amounting, in 1873, to 577,085 souls. Much of the land is low-lying swamp, covered with a wilderness of impenetrable bush; but in the south it rises into mountains, of which Oeloe Moesi (Ulu Musi) is 6180 feet. Gold-dust, iron-ore, sulphur with arsenic, lignite, and common coal are found; also clays suited for making coarse pottery, &c. Springs of pure oil occur near the coal-fields of Bali Boekit (Bukit), and of mineral water in various places. Rice, cotton, sugar, pepper, tobacco, and, in the interior, cocoa-nuts, are grown; the forests producing gutta-percha, gum-elastic, rattans, wax, benzoin, satin-wood, &c. The rivers abound with fish; and the elephant, rhinoceros, tiger, panther, and leopard roam the woods, as well as the deer, wild swine, and goats, with many varieties of the monkey.

In the dry season the thermometer ranges from 80° to 92° F., and in the rainy season 76° to 80°. The climate is not unhealthy, except in the neighborhood of the swamps. The natives are descended from Javanese, who in the 16th c., or earlier, settled in P., and ruled over the whole land. The race, however, has become mixed with other Malays, and the language has lost its purity. In the north-west interior is a tribe called the Koeboes (Kubus), of whose origin nothing is known, but who are probably the remainder of the aborigines. They do not follow after agriculture, go about almost naked, and live chiefly by fishing and hunting. No idea of a Supreme Being seems to be possessed by them, though they believe in existence after death.

PALEMBANG, the capital of the kingdom and residency, is 52 miles from the Soemsang (Sunsang), or principal mouth of the river Moesi (Musi), in 2° 59' S. lat., and 104° 44' E. long. The city is built on both banks of the Moesi, and other streams which fall into it, and is five miles in length by half a mile in breadth. The river is upwards of 1000 feet broad, and from 40 to 50 feet in depth, so that the largest vessels can sail up to the harbor. The native houses are raised on posts, and neatly constructed of

planks or bamboos; the Chinese, Arabians, and Europeans, chiefly living in floating houses called rakits, of which there are upwards of 500, and holding communication with one another and with the natives by boats. The fort is built on the left bank of the river, and behind it are an institution for the blind and a splendid mosque. There is a school, where 30 European children are educated, a government elementary school for natives, and several good Chinese schools. Many of the natives can read and write, and in 1856 a native printing-press was erected by Kemas Mohamed Asahel.

P. is visited annually by upwards of 80,000 boats of various sizes, bringing produce from the interior, consisting chiefly of rice, benzoin, gum-elastic, gutta-percha, raw cotton, rattans, tobacco, pepper, wax, dragon's blood, resin; and gold-dust from the boundaries of the kingdom of Djambi, now included in the Residency. These are obtained chiefly in exchange for salt, cotton manufactures, earthenware, iron and copper wares, and provisions. The foreign trade is large, and chiefly carried on with Java, Banca, Singapore, China, and Siam. The imports into P., which considerably exceed the export thence, have an average annual value of near £300,000. The natives of P. are good ivory carvers, gold and silver smiths, jewellers, cutlers, japanners, painters, boat-builders, bookbinders, &c., and expert at all the ordinary handicrafts. The women, in addition to cotton fabrics, spinning, and dyeing, weave silk stuffs embroidered with gold. Pop. 44,000, of whom 100 are Europeans, 3000 Chinese, and 2000 Arabians.

PALE'NCIA (the ancient *Pullantia*), a city of Spain, in Old Castile, capital of the modern province of the same name, stands in a treeless, but well-watered and fruitful plain, on the Carrion, 30 miles north-east of Valladolid. It is a bishop's see, and is surrounded by old walls, 36 feet high and 9 feet thick, around which are pleasant promenades. The cathedral, a light and elegant Gothic edifice, was built 1321—1504. The first university founded in Castile was built here in the 10th c., but was removed to Salamanca in 1239. Nearly one-third of the population is employed in the manufacture of blankets and coarse woollen cloths. The position of the town on the Carrion, and on the Castilian Canal, is favorable to the development of commerce. The vine is cultivated, and there is a good trade in wool. Pop. (1877) 14,505.

PALE'NQUE, RUINS OF, are on the Rio Chacamas, a branch of the river Usumasinta, in the state of Chiapas, Mexico, 8 miles south-east of the village of Santo Domingo de Palenque, lat. 17° 30' N., long. 92° 25' W. The ruins extend over a large area covered with a dense tropical forest, and are of difficult exploration. They consist of vast artificial terraces, or terraced truncated pyramids, of cut stone, surmounted by edifices of peculiar and solid architecture, also of cut stone, covered with figures in relief, or figures and hieroglyphics in stucco, with remains of brilliant colors. Most of the buildings are of one story, but a few are two, three, and some may have been four stories. The principal structure, known as the Palace, is 228 feet long, 180 feet deep, and 25 feet high, standing on a terraced truncated pyramid of corresponding dimensions. It was faced with cut stone, cemented with mortar of lime and sand, and the front covered with stucco and painted. A corridor runs around the building, opening into four interior courts, which open into many smaller rooms. On slabs of stone are carved numerous colossal figures, and the remains of statues more resemble Grecian than Egyptian or Hindu art. Other spacious and elaborately ornamented buildings appear to have been temples of religion. These ruins were in the same condition when Cortez conquered Mexico, as now, over-grown with a forest, and their site forgotten. They were only discovered 1750.

Three explorations were made by the Spanish government, but they were little known until visited by Messrs J. L. Stephens and F. Catherwood, and their account published with plans and drawings. See Stephen's *Incidents of Travel in Central America*, &c., and Catherwood's *Views of Ancient Monuments of Central America*, &c. There are in Mexico dim traditions of the existence, at a remote period, of the capital of a theocratic state, the center of a long since extinguished civilization, of which the only traces are these wonderful ruins and unexplained hieroglyphics.

PALE'RMO, an archiepiscopal city, important seaport, and the capital of the island of Sicily; capital also of the province of the same name, and along with Naples, Rome, Milan, and Turin, one of the five most populous cities in the kingdom of Italy, is situated on the north coast of the island, 135 miles by water west of Messina. Lat. 38° 6' N., long. 13° 20' E. It stands in a highly-cultivated and fertile plain called *La Conca d'Oro* (The Golden Shell), commands a beautiful view of the Gulf of Palermo on which it stands, and is backed toward the interior by ridges of mountains.

In shape the town is an oblong parallelogram, the direction of its length being from south-west to north-east. It is divided into four quadrangular parts by two great streets, the beautiful Via Vittorio Emanuele, formerly the *Via Toledo*, or *Cassaro*, and the

Strada Nuova or *Macqueda*, which cross each other at right angles in the middle of the city. It is upwards of four miles in circumference, is surrounded by walls pierced by 12 gates and flanked with bastions, and is defended by several batteries. The houses are balconied, flat roofed, and have glass doors instead of windows. The streets, besides the two main thoroughfares already mentioned, are generally well laid out, and there are several fine promenades, of which the famous *Marina*, extending along the shore, on the line of the ancient fortifications, and bordered by the palaces of the nobles, is the most magnificent. P. contains 60 parish churches; 8 abbeys; 71 monasteries and convents, to which belong from 20,000 to 30,000 monks and nuns; and, besides these, 19 oratories. Under the churches is counted the cathedral—the church of St. Rosalie.

At the intersection of the two principal streets there is a large octagonal space or *Piazza*, lined with palaces, and adorned with statues and marble fountains. The royal palace is a huge pile of buildings, with a splendid chapel, built in 1129, and contains many pillars of rare workmanship and rich mosaics with Arabic inscriptions. The cathedral is a fine edifice, originally Gothic, but to which incongruous Greek additions have been made, is adorned with marble columns and statues, and contains monuments of the Emperor Frederick II. and of King Roger, the founder of the Norman monarchy in Sicily. Among the principal public institutions of P. are the university, an academy of art and sciences, a medical academy, an institution for arts and antiquities, a beautiful and extensive public garden, public libraries, theaters, &c. P. is an archbishop's see, the residence of the governor of the island, and the seat of the supreme courts. Manufactures of silks, cottons, oil-cloth, leather, gloves, &c., are carried on. The harbor is formed by a mole, 1300 feet in length, on which there is a light-house and battery. Vessels of 700,000 tons enter and clear the port annually, and the imports amount in value to near £1,000,000, and the exports to about the same sum. Pop. (1871) of P. with suburbs, 186,406; (1881) 205,712.

The environs of P. are interesting as well as picturesque, and embrace many pleasant villas and noble mansions. North-west of the city is Monte Pellegrino, the Eirete of the ancients, an abrupt rocky mass, in which there is a grotto or cave, in which Santa Rosalia, a young Norman princess, lived a life of religious retirement. In P., Santa Rosalia is esteemed more highly than even Santa Maria; the festival in her honor lasts from the 9th to the 13th July, and is the most important festival held on the island. During its celebration the city is illuminated, the streets are gay and brilliant, and there is an immense influx of strangers from the vicinity. But the chief feature of the festival is the procession to the cave. An immense silver image of the saint is borne thither on a wagon, 70 feet long, 30 feet broad, and 80 feet high. Its form resembles that of a Roman gallery, with seats for a choir. The wagon is drawn by 56 mules, covered with the gayest trappings, and driven by 28 postillions.

P., the ancient *Panormus*, was originally a Phœnician colony, but had become a dependency of Carthage before the name occurs in history. With the exception of a short time about 276 B.C., when it fell into the hands of the Greeks, it continued to be the head-quarters of the Carthaginian power in Sicily, until it was taken by the Romans during the first Punic War (254 B.C.), when it became one of the principal naval stations of the Romans. The name *Panormus* is derived from the excellent anchorage (Gr. *hormos*) in the bay; but the Phœnician name found on coins is *Machanath*, meaning 'a camp.' The Vandals, and afterwards the Arabs, made it the capital of the island, and after the Norman Conquest it continued to be the seat of the king of Sicily. It still remained the royal residence under the Aragonese kings; but the court was removed after Sicily became united to the then kingdom of Naples. See SICILY.

PA'LESTINE (*Palestina*, *Philistia*), or the HOLY LAND, a country of South-Western Asia, comprising the southern portion of Syria, and bounded on the W. by the Mediterranean, E. by the valley of the Jordan, N. by the mountain-ranges of the Lebanon and the glen of the Litány (Leontes), and S. by the Desert of Sinai; lat. 31° 15'—38° 20' N., long. 34° 30'—35° 30' E. Within these narrow limits, not more than 145 miles in length by 45 in average breadth—an area less than that of the principality of Wales—is comprised the 'Land of Israel' or 'Canaan,' the arena of the greatest events in the world's history. The principal physical features of P. are, (1) a central plateau or table-land, with a mean height of 1600 feet, covered with an agglomeration of hills, which extend from the roots of the Lebanon to the southern extremity of the country; (2) the Jordan valley and its lakes; and (3) the maritime plain, and the plains of Esdraëlon and Jericho. On the east, the descent from the central plateau is steep and rugged, from Lake Huleh to the Dead Sea. On the west, it is more gentle, but still well marked, towards the plains of Philistia and Sharon. The ascertained altitudes on this plateau, proceeding from south to north, are Hebron, 3029; Jerusalem,

2610; Mount of Olives, 2724; Mount Gerizim, 2700; Mount Tabor, 1900; Safed, 2775 feet above the sea. Nearly on the parallel of the Sea of Galilee, the range of Carmel extends from the central plateau north-west to the Mediterranean, where it terminates abruptly in a promontory surmounted by a convent. It rises from 600 feet in the west, to 1600 feet in the east, and is composed of a soft white limestone, with many caverns.

Beyond the boundary of P. on the north, but visible from the greater part of the country, Mount Hermon rises to 9381 feet, and is always snow-clad. From the formation of the central plateau, the drainage is nearly always east and west, to the Jordan and the Mediterranean. The streams of the plateau are insignificant, and generally dry in summer.

The geological formation of the country consists of jurassic and cretaceous limestone, often covered with chalk, and rich in flints, with occasional interruptions of tertiary, basaltic, and trappan deposits. The upper strata consists of limestone of a white or pale-brown color, containing few fossils, but abounding in caverns, which form one of the peculiarities of the country. The general features of the landscape exhibit soft rounded hills, separated by narrow glens or valleys of denudation; the strata are occasionally level, but more frequently violently contorted, as seen on the route from Jerusalem to Jericho, where the fissures are often 1000 feet deep, and only 30 or 40 feet wide. Ironstone occurs in small quantities; rock-salt, asphaltum, and sulphur abound near the Dead Sea, where, as also near the Sea of Galilee, there are many hot springs. Volcanic agency is evident in the obtruded lava of former ages, and in frequent earthquakes of modern times.

The vast crevasse through which the Jordan flows, and which cleaves the land from north to south, is one of the most remarkable fissures on the surface of the globe; it is from 5 to 12 miles wide, and of the extraordinary depth of 2630 feet at the bottom of the Dead Sea. Through this the river descends at the rate of 11 feet in a mile, with a course so tortuous that it travels 132 miles in a direct distance of 64, between the Sea of Galilee and the Dead Sea. It is the only perennial river of P., except the Kishon, which is permanent only in its lower course, and the Litány on its northern border. See JORDAN. The only lakes of P. are in the valley of the Jordan. See GENNESARET, SEA OF, and DEAD SEA.

The plain of Philistia extends from the coast to the first rising ground of Judah, about 15 miles in average width; the soil is a rich brown loam, almost without a stone. It is in many parts perfectly level; in others undulating, with mounds or hillocks. The towns of Gaza and Ashdod, near the sea, are surrounded by groves of olives, sycamores, and palms. This plain is still, as it always was, a vast corn-field, an ocean of wheat, without a break or fence; its marvelous fertility has produced the same succession of crops, year after year, for forty centuries without artificial aid. The plain of Sharon is about 10 miles wide in the south, narrowing towards the north, till it is terminated by the buttress of Carmel. Its undulating surface is crossed by several streams; the soil is rich, and capable of producing enormous crops; but only a small portion of it near Jaffa is cultivated, and it is rapidly being encroached on by the sea sand, which, between Jaffa and Casarea, extends to a width of 3 miles and a height of 300 feet.

The famous ancient cities of this region, Casarea, Diospolis, and Antipatris, have vanished. Jaffa (Joppa) alone remains, supported by travelers and pilgrims from the west on the way to Jerusalem. The great plain of Esdraëlon, or Jezreel, extends across the center of the country from the Mediterranean to the Jordan, separating the mountain-ranges of Carmel and Samaria from those of Galilee. Its surface drained by the Kishon, which flows west to the Mediterranean at Haifa. The plain is surrounded by the hills of Gilboa and Little Hermon; the isolated Mount Tabor rises on its north-east side. It is extremely fertile in grain where cultivated, and covered with gigantic thistles where neglected. It is richest in the central part, which slopes east to the Jordan—the battle-field where Gideon triumphed, and Saul and Jonathan were overthrown. It is the home of wandering Bedouins, who camp in its fields, and gallop over its green-sward in search of plunder. Many places of deep historical interest are connected with this plain. Shunem, Naïn, Endor, Jezreel, Gilboa, Bethshan, Nazareth, and Tabor are all in its vicinity. The plain of Jericho is a vast level expanse, covered with the richest soil, now quite neglected. Around the site of Jericho, 'the city of palm-trees,' there is not now a single palm; but a recent experiment proved its capability of producing in abundance all the crops for which it was formerly famous. The climate of P. is very varied; January is the coldest and July the hottest month.

The mean annual temperature of the year at Jerusalem is 65° Fahr., resembling that of Madeira, the Bermudas, and California. The extreme heat of the summer months is modified by sea-breezes from the north-west. In the plain of Jericho and the Jordan valley it is extremely hot and relaxing. The *sirocco*, a south-east wind, is often oppressive in early summer. Snow falls

in the uplands in January and February, and thin ice is often found at Jerusalem, where the annual rainfall is 61 inches. Heavy dews fall in summer, and the nights are cold. Violent thunderstorms occur in winter. In the south, Judah and part of Benjamin, is a dry parched land; the bare limestone rock is covered here and there with a scanty soil, and the vast remains of terraces show how assiduously it must have been cultivated in ancient times to support the teeming population indicated by the ruins of cities with which every eminence is crowned. To the north of Judea the country is more open, the plains are wider, the soil richer, and the produce more varied, till at Nablous the running streams and exuberant vegetation recall to the traveler the scenery of the Tyrol. Even in its desolation, P. is a land flowing with milk and honey. There is no evidence of its climate having changed or deteriorated, nor any reason to suppose that it would fall to support as great a population as ever it did, provided the same means as formerly were used for its cultivation. It has the same bright sun and unclouded sky, as well as the early and latter rain, which, however, is diminished in quantity, owing to the destruction of trees.

The botany of P. is rich and varied, resembling that of Asia Minor. Among its trees are the pine, oak, elder, and hawthorn in the northern and higher districts, and the olive, fig, carob and sycamore elsewhere. The cultivated fruits are the vine, apple, pear, apricot, quince, plum, orange, lime, banana, almond, and prickly pear. Wheat, barley, peas, potatoes, and European vegetables, cotton, millet, rice, maize, and sugar-cane are among its products. The date now ripens its fruit only in the south and on the sea-board. The brilliant flowers which in spring enamel the surface and tinge the entire landscape, comprise the adonis, ranunculus, mallow, poppy, pink, anemone, and geranium. In the Jordan valley, 900 or 1000 feet below the sea-level, the vegetation is tropical in its character, resembling that of Arabia; the nubb (*Spina Christi*), the oleander, and the small yellow 'apples of Sodom' are conspicuous. The most valuable products of the vegetable kingdom are derived from the vine, fig, olive, and mulberry trees. Wine for home use is made in all the central and southern districts; the best is made at Hebron from the grapes of Eschool. Olive oil is a valuable export.

The wild animals of P. comprise the Syrian bear in Lebanon, the panther, jackal, fox, hyena, wolf, wild boar, gazelle, and fallow-deer; the lion is now unknown. The domestic animals are the Arabian camel, ass, mule, horse, buffalo, ox, and broad-tailed sheep. Among the birds are the eagle, vulture, kite, owl, nightingale, jay, and kingfisher—the latter of brilliant plumage—the cuckoo, heron, stork, crow, partridge, and sparrow. Fish swarm in the Sea of Galilee, and bats and lizards abound.

The divisions of P. in Old Testament times were into 2½ tribes in the west, and 2½ tribes in the east of the Jordan. In New Testament times, on the west of the Jordan, the provinces of Galilee in the north, Samaria in the middle, and Judea in the south; on the east of the Jordan, Perea and Decapolis. The boundaries of the tribes and provinces are very uncertain. Under Turkish rule, P. is comprised in the vilayet of Syria. The present population, probably not exceeding 700,000, consists mainly of a race of mixed descent, sprung from Syrians, Arabs, and Greeks; they speak Arabic, and are mostly Moslems, some of them nomadic. There are a number of Greek Christians of Syrian descent; a few official Turks, some Maronites, Roman Catholics, and Armenians. The Jews, a few thousands in number, are mostly from Spain and Germany, and are found only in Jerusalem, Hebron, Tiberias, and Safed. A colony of some 750 Germans established themselves some years ago about Carmel and Jaffa. The country is oppressed by Turkish avarice, and overrun by the predatory Arabs. The Palestine exploration societies, English and American, organized in 1865, have done good work in the identification of Biblical and classical sites. See SYRIA.

PALESTRINA, an Italian city 23 miles E.S.E. of Rome, on the slope of an offset of the Apennines. Besides several interesting churches, the town contains a castle, once the chief stronghold of the Colonna, to whom the town belonged; and the palace and garden of the Barberini family. The view across the Campagna and towards the Alban Hills is magnificent. Pop. 6000, who manufacture coarse woollen goods.

P. is built almost entirely upon the site and the gigantic substructions of the Temple of Fortune, one of the great edifices of the former city of Præneste. This city was one of the most ancient as well as powerful and important cities of Latium. It covered the hill (2400 feet above sea-level) on the slope of which the modern town stands, and was overlooked by a citadel of great strength. The site of this citadel on the summit of the hill is now occupied by a castle of the middle ages, called *Castel S. Pietro*; but remains of the ancient walls are still visible. We first hear of Præneste as a member of the Latin League; but in 499 B.C. it quitted the confederacy, and joined the cause of the Romans. In

380 B.C., the Prænestines, having rejoined their ancient allies, opened a war with Rome; but were completely routed on the banks of the Allia by T. Quintus Cincinnatus, and beaten back to their own gates. They took a prominent part in the famous Latin War, 340 B.C.

Having given shelter to the younger Marius in the year 82 B.C., this city was besieged by the forces of Sulla, and on its being taken all the inhabitants were put to the sword. A military colony was then established in their place, and soon the city began to flourish anew. Its elevated and healthy situation, at no great distance from the capital, made it a favorite place of resort for the Romans during summer. Augustus frequented it; Horace often found this city a pleasant retreat; and here Hadrian built an extensive villa. The Temple of Fortune is described by Cicero as an edifice of great antiquity as well as splendor, and its oracle was much consulted. The town became the stronghold of the family of Colonna in the middle ages; but was given to the Barberini family by Urban VIII.

PALESTRINA, GIOVANNI PIERLUIGI DA, a distinguished musical composer of the 16th century. He derived his surname from the town of Palestrina, in the Roman States, where he was born in 1524. At the age of sixteen, he went to Rome, and studied music under Claude Goudimel, afterwards one of the victims of the St. Bartholomew massacre. In 1551 he was made *maestro di capella* of the Julian Chapel, and in 1554 he published a collection of Masses, so highly approved of by Pope Julius III., to whom they were dedicated, that he appointed their author one of the singers of the pontifical chapel. Being a married man, he lost that office on the accession to the pontificate of Paul IV., in whose eyes celibacy was a necessary qualification for its duties. In 1555 he was made choir-master of St. Maria Maggiore, and held that position till 1574, when he was restored to his office at St. Peter's.

In 1563, the council of Trent having undertaken to reform the music of the church, and condemned the profane words and music introduced into masses, some compositions of P. were pointed to as models, and their author was intrusted with the task of remodelling this part of religious worship. He composed three masses on the reformed plan; one of them, known as the Mass of Pope Marcellus (to whose memory it is dedicated), may be considered to have saved music to the church by establishing a type infinitely beyond anything that had preceded it, and amid all the changes which music has since gone through, continues to attract admiration. During the remaining years of his life, the number and the quality of the works of P. are equally remarkable. His published works consist of 13 books of Masses, 6 books of Motets, 1 book of Lamentations, 1 book of Hymns, 1 book of Offertories, 1 book of Magnificats, 1 book of Litanies, 1 book of Spiritual Madrigals, and 3 books of Madrigals. P. must be considered the first musician who reconciled musical science with musical art, and his works form a most important epoch in the history of music. Equally estimable in private life, and talented as a musician, P. struggled through a life of poverty during eight pontificates; his appointments were meager, and his publications unremunerative. He died in 1594. A memoir of his life and writings has been written by the Abbé Baini.

PALESTRO, a village of Piedmont, 8 miles south-east of Vercelli, famous as the scene of a battle between the Sardinians and Austrians in May 1859. On the 30th of that month the Piedmontese drove the Austrians from this village, and on the 31st defended it with great bravery against an Austrian attack. The Piedmontese in the battle of the 31st were assisted by 3000 French Zouaves, and on that occasion the Austrians lost 2100 men killed and wounded, 950 prisoners, and 6 pieces of canon. On June 1st the allies entered Novara.

PALETTE. See PAINTING.

PALEY, DR. WILLIAM, a celebrated English divine, was born at Peterborough in 1743. His father was a Yorkshirer, and not long after P. was born returned to his native parish of Giggleswick, one of the wildest and most sequestered districts in the West Riding, to become master of the grammar-school there. Young P. was brought up among the shrewd, hard-headed peasantry of Yorkshire; and it is probable that he either naturally possessed, or insensibly acquired their moral and mental characteristics. At all events, he soon became conspicuous in the family for his good sense; and when he left to enter Christ's College, Cambridge, as a sizar, in his sixteenth year, his father said: 'He has by far the clearest head I ever met with.' At Cambridge, P. led for the first two years a gay, idle, and dissipated life, but thereafter became a severe student, and took his bachelor degree in 1763 with highest honors. He then taught for three years in an Academy at Greenwich.

In 1765 he obtained the first prize for a prose Latin dissertation—the subject being 'A Comparison between the Stoic and Epicurean Philosophy with respect to the Influence of each on the Morals of a People,' in which he characteristically argued in favor

of the latter. Next year he was elected a Fellow and Tutor of Christ's, and also took the degree of M. A. In 1767 he was ordained a priest. His career as a college tutor, which lasted about ten years, was eminently successful; and it appears to have been during this period that he systematized his principles in moral and political philosophy. In 1776, P. married, and was of course obliged to give up his fellowship, but was compensated by a presentation to the livings of Mosgrove and Appleby in Westmoreland and of Dalston in Cumberland. Four years later he was collated to a prebendal stall in the cathedral church of Carlisle, in 1782 he became archdeacon, and in 1785 chancellor of the diocese. The last of these years witnessed the publication of his *Elements of Moral and Political Philosophy*. In this work he propounds his ethical theory, which is commonly called utilitarianism, but is really a mixture of utility and theology. He begins by renouncing the favorite doctrine of the Moral Sense, against which he adduces a series of strong objections. He then takes up the question of the source of obligation, and resolves it into the will of God, enforced by future punishment, admitting candidly that virtue is prudence directed to the next world. The will of God, in so far as it is not rendered explicit by revelation, is to be interpreted by the tendency of actions to promote human happiness; the benevolence of the Deity being supposed.

Objection has frequently been taken to the principles on which P. rests his system, but the lucidity and appositeness of his illustrations are beyond all praise. If his treatise cannot be regarded as a profoundly philosophical work, it is at any rate one of the clearest and most sensible ever written, even by an Englishman; and if it failed to sound the depths of 'moral obligation,' it at least brushed off into oblivion the shallow and muddy mysticism that had long enveloped the philosophy of politics. P.'s plain sarcastic view of the 'divine right of kings,' which he puts on a level with the 'divine right of constables,' gave extreme offence to George III., but was nevertheless much admired by not a few of his majesty's subjects, and is now held by everybody to be beyond question. In 1790 appeared his most original and valuable work—the *Horæ Paulinæ, or the Truth of the Scripture History of St. Paul evinced by a Comparison of the Epistles which bear his Name with the Acts of the Apostles, and with one another*. The aim of this admirable work is to prove, by a great variety of 'undesigned coincidences,' the improbability, if not impossibility, of the usual infidel hypothesis of his time—viz., that the New Testament is a 'cunningly-devised fable.' It was dedicated to his friend John Law, then Bishop of Killala in Ireland, to whose favor he had been indebted for most of his preferments. P.'s next important work was entitled *A View of the Evidences of Christianity*, published in 1794. It is not equal in originality to its predecessor, but the use which the author has made of the labors of such eminent scholars as Lardner and Bishop Douglas is generally reckoned most dexterous and effective.

Later and keener criticism is indeed anything but satisfied with P.'s 'Evidences,' but in P.'s own day he was held to have achieved a splendid triumph over sceptics, and was handsomely rewarded. The Bishop of London appointed him a prebend of St. Pancras; shortly after he was promoted to the subdeanery of Lincoln (worth £700 per annum); Cambridge conferred on him the degree of D.D.; and the Bishop of Durham the rich rectory of Bishop Wearmouth (worth £1200 per annum), in consequence of which he honorably resigned his livings in the diocese of Carlisle. After 1800 he became subject to a painful disease of the kidneys, but notwithstanding he continued to write, and in 1802 published perhaps the most widely popular of all his works, *Natural Theology, or Evidences of the Existence and Attributes of the Deity*, which, however, is based, and to a large extent borrowed from the *Religious Philosopher*, the work of a Dutch philosopher named Nieuwentijt, an English translation of which appeared in 1718—1719. The plagiarisms are most palpable, but have been accounted for on the supposition that the *Natural Theology* was 'made up' from his loose papers and notes written when P. was a college tutor, and that he had forgotten the sources from which he derived them. It is also but fair to state that he has taken nothing which he has not greatly improved; *nihil tetigit, quod non ornavit*. A somewhat noted edition of this work, enriched, or at least expanded by annotations and dissertations, is that by Lord Brougham and Sir Charles Bell (1836—1839). P. died May 25, 1805. He had a family of four sons and three daughters. A complete edition of his works was published in 1838 by one of his sons, the Rev. Edmund Paley. The best biography is that by Meadley (1809).

PALGRAVE, SIR FRANCIS, a distinguished antiquary and historian, was born in London in July 1788, of Jewish parentage, being the son of Mr. Meyer Cohen, a member of the Stock Exchange. He was educated at home under a Dr. Montucci, and even when a child showed extraordinary genius. When only eight years old, he made a translation into French of the *Battle of the Frogs and Mice* from the Latin version of Beauclerc, which

was printed by his father in 1797. In 1803 he was articled as a clerk to a legal firm, and at the expiration of his articles, continued with the same firm as managing clerk until 1822, when he took chambers in the Temple, and was employed under the Record Commission. He had previously made himself known as a literary antiquarian, by the publication in 1818, of some Anglo-Norman Chansons, which he edited with much care. On the occasion of his marriage in 1823, he changed his name of Cohen to P., that being the maiden name of his wife's mother. He was called to the bar in 1827, and had considerable practice for some years in pedigree cases before the House of Lords. In 1831 he published a *History of England*, which formed a part of the *Family Library*; and in 1832 appeared his *Rise and Progress of the English Commonwealth*; also *Observations on the Principles, &c., of New Municipal Corporations*. In that year he received the honor of knighthood, and was subsequently one of the Municipal Corporation Commissioners. In 1835, the Commissioners issued their Report, which was signed, however, by only sixteen of the members—Sir F. P. being one of the four dissentients. In the same year he published a 'Protest' against the Commissioners' Report, in which he called in question several of its statements, views, and arguments.

In 1838, on the reconstruction of the Record Service, Sir F. P. was appointed deputy-keeper of Her Majesty's Records, and held that office during the rest of his life. Besides the works already mentioned, Sir F. P. edited for the government the following: *Calendars of the Treasury of the Exchequer, Parliamentary Writs, Curia Regis Records, and Documents Illustrative of the History of Scotland*. In his private capacity, he produced the *Merchant and the Friar*, an imaginary history of Marco Polo and Friar Bacon; also a *Hand-book for travellers in Northern Italy*, and a *History of England and Normandy*. Of this last work a volume appeared in 1851, and a second in 1857; and the third and fourth volumes were published within three years after their author's death. Sir F. P. also wrote numerous articles for the *Edinburgh and Quarterly Reviews*, principally of an antiquarian character, but some of them purely literary or artistic. His great merit, in his historic writings, consists in the extensive use made by him of original documents, by aid of which he not only himself very much enlarged our acquaintance with the history and social aspects of the middle ages, but pointed out to others the advantage to be derived from a careful study of the original sources of information now known to abound among our public records. Sir F. P. died at Hampstead, on the 6th of July 1861.

PALI (a corruption of the Sanscrit *Prākṛit*, q. v.) is the name of the sacred language of the Buddhists. Its origin must be sought for in one or several of the popular dialects of ancient India, which are comprised under the general name of *Prākṛit*, and stand in a similar relation to Sanscrit as the Romance languages, in their earlier period, to Latin. It has been formerly assumed that P. arose from the special *Prākṛit* dialect called *Māgadhī*, or the language spoken in Magadha; but, according to the view expressed by Lassen in his *Indische Alterthumskunde*, an hypothesis of this kind is not tenable, since the peculiarities of this dialect are not compatible with those of the P. language. The same distinguished scholar holds that the *Prākṛit* dialects, called the *Sauraseni* and *Māhārāṣṭrī*, have a closer relation to the P. than any other, and that the origin of the latter must therefore be traced to the country of Western Hindustan, between the Jumna river and the Vindhya mountain; though he observes, at the same time, that the P. is older than these dialects, and that the latter are therefore more remote from Sanscrit than the former. Whether the oldest works of the Buddhist religion were written in P. may be matter of doubt. It is more probable, on the contrary, that the language in which the founder of the Buddhist religion conveyed his doctrine to the people was not yet that special language, but a mixture of classical and popular Sanscrit, such as it still appears in the Buddhist *Sūtras*. At a later period, however, P. became the classical language in which the Buddhists wrote their sacred, metaphysical, and profane works.

The most important historical work written in this language is the *Mahāvamsa* (q. v.); other P. works, which have lately become known in Europe, and deserve especial mention, are the *Dhammapadam*, on the Buddhist doctrine, and five *Jātakas*, containing a fairy tale, a comical story, and three fables—both works edited and translated by V. Fausbøll (Copen. 1855 and 1861). P. ceased to be a living language of India when Buddhism was rooted out of it; it was carried by the fugitive Buddhists to other countries, especially Ceylon, Burmah, and Siam; but in these countries, too, it had to give way before the native tongues, in which the later Buddhist literature was composed.

PA'LIMPSEST (Gr. *palimpsestos*, 'rubbed a second time'), the name given to parchment, papyrus, or other writing material, from which, after it had been written upon, the first writing was wholly or in part removed for the purpose of the page being written upon a second time. When the MS. had been written with

one species of ink employed by the ancients, which was merely a fatty pigment, composed chiefly of lampblack, and only coloring the surface, but not producing a chemical change, there was little difficulty in obliterating the writing. It was accomplished by the use of a sponge, and if necessary, of a scraper and polishing tool; and, where proper pains were taken, the erasure of the first writing was complete. But when the ink was mineral, its effect reached beyond the surface. In that case a scraping-tool or pumice-stone was indispensable; if these were hastily or insufficiently applied, the erasure was necessarily imperfect; and thus it often happens in ancient MSS. that, from the want of proper care on the part of the copyist in preparing the parchment for re-writing, that original writing may still be read without the slightest difficulty.

The practice of re-preparing used parchment for second use existed among the Romans. The material thus re-prepared was of course reserved for the meaner uses. We meet frequent allusions in the classical writers, as Plutarch, Cicero (*Ad Familiares*, vii. 18), Catullus (xxii. 115) and others, to the palimpsest, in the sense of a blotter or first draft-book, on which the rough outline or first copy of a document was written, preparatory to the accurate transcript which was intended for actual use; and it appears equally certain that in many cases whole books were written upon re-prepared parchment or papyrus, not only among the Greeks and Romans, but also among the ancient Egyptians.

Of palimpsests of the classic period, however, it is hardly necessary to say no specimen has ever been discovered. It is to the necessities of the medieval period that literature owes the unquestionably important advantages which have arisen from the revival of the ancient practice of re-preparing already used material for writing. Under the early emperors, the intercourse with Egypt and the east secured a tolerably cheap and abundant supply of Papyrus (q. v.), which rendered it unnecessary to recur to the expedient of the palimpsest; and this became still more the case in the 5th and 6th centuries, when the tax on papyrus was abolished. But after the separation of east and west, and still more after the Mohammedan conquest of Egypt, the supply of papyrus almost completely ceased; and from the 7th c. in the west, and the 10th or 11th in the east, the palimpsest is found in comparatively frequent use; and its frequency in the 15th c. may be estimated from the fact that some of the earliest books were printed on palimpsest.

Some writers have ascribed the prevalence of its use to the indifference, and even to the hostility of the monks and clergy to classical literature, and have attributed to their reckless destruction of classic MSS., in order to provide material for their own service-books and legends, the deficiencies in the remains of ancient learning which scholars have now to deplore. That some part of the loss may have so arisen, it is impossible to doubt, although it is equally certain that we owe to the medieval monks and clergy whatever of ancient literature has been preserved to our day. But the condition in which the existing palimpsests are uniformly found—for the most part mere fragments of the ancient writers whose works they originally contained—goes far in itself to show that the MSS. which were broken up by the medieval copyists, for the purpose of being re-written, were almost always already imperfect or otherwise damaged; nor is there anything in the condition of any single palimpsest which has reached our day to justify the belief, that when it was taken up for the purpose of rescription, the original work which it contained was in a state at all approaching to completeness. Fortunately, however, there are many of the relics of ancient learning of which even the mutilated members have an independent value; and this is especially true of Biblical MSS., particularly under the critical aspect, and in a still broader sense, of all the remains of the ancient historians.

It will easily be understood, therefore, that the chief, if not the sole interest of palimpsest MSS. lies in the ancient writing which they had contained, and that their value to literature mainly depends on the degree of legibility which the ancient writing still retains. It is difficult to make this fully intelligible to the reader without an actual inspection, but the facsimile which is annexed will furnish a sufficient idea. The particular passage selected for the illustration is from page 63 of the Vatican MS., from which

Mai deciphered the fragments of the *De Republica*. The darker letters are those of the modern MS.; the faint lines are, as may be supposed, those of the original codex. Although so much more faint than the modern writing, they can be read with facility on account of their greater size. We shall transcribe both texts in ordinary characters. The original was as follows:

EST
IGITUR INQUIT
AFRICANUS RESP.

(The ordinary contraction for *Respublica*.)

The corresponding lines of the modern MS., which is from St. Augustine's commentary on the Psalms, are—

homos est quia
et omnes *Xpiani* (Christiani) membra sunt *Xpi*. (Christi)
membra *Xpi*. quid cantant. Amant
Desiderando cantant. Aliquando

In this specimen, as very commonly occurs, the original writing is much larger than the modern; the modern lines and letters do not cover those of the old MS., but they follow the same order. In other specimens the new writing is transverse; in some, the old page is turned upside down. Sometimes, where the old page is divided into columns, the new writing is carried over them all in a single line; sometimes the old page is doubled, so as to form two pages in the new MS. Sometimes it is cut into two, or even three pages. The most perplexing case of all for the decipherer is that in which the new letters are of the same size, and are written upon the same lines with those of the original MS. Examples of this are rare, and even when they occur, the difference between the form of the ancient characters, which are ordinarily uncial, and that of the modern, is in itself a great aid to the decipherer. Some variety, also, is found in the language of the palimpsests. In those which are found in the western libraries, the new writing is almost invariably Latin, while the original is sometimes Greek, and sometimes Latin. In the palimpsests discovered in the east, the original is commonly Greek, the new writing being sometimes Greek, sometimes Syriac, sometimes Armenian; and one palimpsest, the material of which is papyrus, is found in which the original was the enchorial Egyptian language, while the modern writing is Greek.

The possibility of turning palimpsest MSS. to account as a means of extending our store of ancient literature, was suggested as far back as the days of Montfaucon; but the idea was not turned to practical account till the latter part of the 18th century. The first palimpsest editor was a German scholar, Dr. Paul Bruns, who having discovered that one of the Vatican MSS. was a palimpsest, the effaced matter of which was a fragment of the 91st book of Livy's *Roman History*, printed it at Hamburg in 1773. In the field of discovery thus opened by Bruns but little progress was made until the following c., when Dr. Barrett of Trinity College, Dublin, published his palimpsest Fragments of St. Matthew, and when palimpsest literature at once rose into interest and importance in the hands of the celebrated Angelo Mai (q. v.). A detailed account of Mai's successes will be given hereafter, when we shall enumerate the principal publications in this curious department of letters; and under his own name will be found the history of his personal labors. The great historian Niebuhr about the same time applied himself to the subject, and was followed by Blume, Pertz, Gaupp, and other German scholars, whose labors, however, were for the most part confined to the department of ancient Roman law. More recently, the discoveries of Dr. Tischendorf in Biblical literature, and those of Dr. Cureton as well in sacred as in profane literature, have contributed still more to add importance to the palimpsest MSS. which have been supposed to exist in the monasteries of the Levant.

Herr Mone has had similar success in the department of liturgical literature, and Dr. Frederick Augustus Pertz, son of the scholar already mentioned, may be said to have carried to its highest point the interest which attaches to these curious researches, by editing from a *thrice written palimpsest* a very considerable series of fragments of the Roman annalist, Gaius Granius Licinianus.

It remains to enumerate briefly the most important palimpsest publications which have hitherto appeared, distributed according to the language of the effaced original.

I. GREEK PALIMPSESTS.—Among these, the first place of course belongs to the Greek Biblical palimpsests, the earliest of which was (1) *Fragments of the Gospel of St. Matthew*, in facsimile as well as in ordinary type, printed from a palimpsest MS. of Trinity College, Dublin, by the Rev. I. Barrett, D.D. (4to, Dublin, 1801). The original writing appears to be of the 6th century.

boengest quia
et omnes xpiani membra sunt xpi
igitur inquit
membra xpi. quid cantant. Amant
desiderando cantant. Aliquando

Dr. Barrett's transcript of the text has not proved in all respects correct, but the original has since been carefully re-examined, and the ancient writing fully brought out. It is chiefly, however, to a collection of Syriac MSS. brought from the east that we are indebted for the more recent palimpsest restorations of the ancient Biblical readings. In this line the chief discoverer has been Dr. Constantine Tischendorf. From his pen we have (2) the celebrated *Codex Ephremi* or *Codex Regius* of the Royal Library at Paris. This MS. had been early observed to be palimpsest, and the original Greek text was collated in part by Wetstein and by Kuster. It was still more carefully examined by M. Hase in 1835; and finally, in 1840, by Dr. Tischendorf, by whom the New Testament was printed in 1843, and the fragments of the Old in 1845. The modern writing of this palimpsest consisted of the works of St. Ephrem the Syrian.

(3) *Fragmenta Sacra Palimpsesta* (4to, Leipsic, 1855), containing fragments of the Books of numbers, Deuteronomy, Joshua, Judges, Kings, Isaiah, together with 48 pages of fragments of the New Testament, the Gospels, the Acts, and the Epistles of St. Paul to the Corinthians and to Titus. The modern writing of these palimpsests was partly Greek, partly Armenian and Arabic. (4) *Fragmenta Evangelii Lucae et Libri Genesis* (4to, Leipsic, 1857). The fragments of St. Luke's Gospel amount to 95 pages. The volume also contains fragments of St. John's Gospel and of Ezekiel and the Third Book of Kings. The modern writing is partly Syriac, partly Coptic. Along with these Biblical palimpsests (5) may be classed another, the original of which, however, contains not only some Greek fragments, but also portions of the ancient Gothic version of the Bible by Ulphilas. The MS. from which this is taken is known from its place in the Wolfenbüttel Library as the *Codex Guelpherbytanus*. It was first noticed in 1755 by Knittel, by whom a portion of the Gothic version was published in 1762. These fragments were reprinted in 1772, and again in 1805. The modern writing of the MS. consisted of the *Origines* of Isidorus Hispalensis. A large addition to the text of Ulphilas was made in 1817 by Mai and Castiglione, from palimpsests discovered in the Ambrosian Library at Milan; and the whole have since been combined into one edition by Dr. Gabelentz and finally by Dr. Massmann (4to, Stuttgart, 1855). We may also mention under the same head some interesting Greek liturgical remains edited by F. I. Mone (Frankfort, 1850), from a palimpsest discovered at Carlsruhe.

In Greek classical literature, also, we owe something to the labors of palimpsest editors. From one of the Syriac MSS. already referred to, Dr. Cureton has edited large fragments of the *Iliad* of Homer, amounting in all to nearly 4000 lines; and although all these, it need hardly be said, were known before, yet the text is of the utmost value as a source of criticism, being certainly of much greater antiquity than the very earliest known MSS. of the *Iliad*. A still larger and more original contribution to Greek classical literature was made by Mai in the 5th volume of his *Scriptorum Veterum Nova Collectio* (Rome, 1831—1838). From a very large palimpsest discovered in the Vatican Library he has printed in this volume copious fragments of almost all the Greek writers on Roman history—from the lost books of Polybius no less than 100 4to pages; 130 pages of Diodorus Siculus; 64 of Dionysius of Halicarnassus; 100 of Dion Cassius; together with considerable fragments of Appian, Iamblichus, Dexippus, Eunapius, and others. This is, perhaps, after the *De Republica* of Cicero, the most important accession to the existing store of classic learning which the palimpsests have hitherto supplied.

II. LATIN PALIMPSESTS.—(1.) The earliest fragment of Latin literature, printed from a palimpsest original is the portion of the 91st book of *Livy* already referred to, published at Hamburg and also at Rome in 1773. It was re-edited in a more complete form by Niebuhr in 1820. (2.) Of the Latin palimpsests edited by Mai, the earliest were some fragments of lost Orations of Cicero from two different palimpsests in the Ambrosian Library at Milan, in the latter of which, the second writing consisted of the acts of the council of Chalcedon. These Orations were published in two successive volumes in 1814. (3.) Eight Orations of Symmachus (1815). (4.) The Comedies of Plautus, including a fragment of the lost play entitled *Vidularia* (1815). (5.) The works of M. Corn. Fronto, together with the Epistles of Antoninus Pius, Lucius Verus, M. Aurelius, and others (1815). (6.) The celebrated Dialogue of Cicero, *De Republica*, from a palimpsest of the Vatican, the modern writing of which is the commentary of St. Augustine on the Psalms. There is none of Mai's publications which presents his critical abilities in so favorable a light as this precious volume which appeared at Rome in 1821. (7.) Soon after the *De Republica* he published another volume from palimpsest sources, the most important of whose contents were some fragments of ancient Roman law, which prepared the way for the more distinguished success of Niebuhr; who, in a palimpsest of the library of Verona, recognized a portion of (8) the *Institutiones* of Gaius, and procured an accurate transcript for the press, which was printed at Berlin in 1820.

The latest considerable Latin publication in this department is (9) *Gaii Gratii Liciniani Annalium quæ supersunt* (Berlin, 1857), edited from a palimpsest of the British Museum by the younger Pertz. This palimpsest, as was already stated, is a thrice written codex, the earliest and original contents being the *Annales* of Gaius Granius. The second writing was also in Latin, and the work is a grammatical treatise, of which the chapters *De Verbo* and *De Adverbio* are still legible. The most modern writing is Syriac, written in the cursive character. Gaius Granius is a writer named by Macrobius, of whom nothing else is known.

It will be gathered from the above that the ancient works recovered by means of palimpsest MSS. are all fragmentary, and one is naturally led to rate at a low value the result thereby obtained. But it must be remembered that in some of the departments to which these fragments belong, every scrap, no matter how trifling, has an independent value. So it is, for example, in Biblical remains—a single text may present a valuable reading, the merest fragment may throw light on an important critical question. In history, in like manner, a small fragment may disclose an interesting fact, or supply a significant commentary upon facts otherwise ascertained. And as regards critical uses especially, it must not be forgotten that the obliterated text of the palimpsest MSS., for the most part, far exceeds in antiquity the very oldest known codices which we possess, and is, probably, second only in age to the papyri of Herculaneum.

The method of treating palimpsest MSS., with a view to deciphering their contents, has been fully described by different editors. Mai, after having washed the palimpsest with an infusion of galls, exposed it to the light and air, and, generally speaking, found this sufficient for his purpose. Peyron washed the parchment in water, afterwards in dilute muriatic acid, and finally in prussiate of potash. A mixture, compounded on this principle, is called from its inventor, M. Gioberti, *Tinctura Giobertina*. Sometimes the same treatment does not succeed equally well on both sides of the parchment; the inner surface, from its softer texture, sometimes requiring a more active preparation. When the ink contained animal substances, as milk, or the blood of the cuttle-fish, Dr. Mone plunged the parchment in a close vessel filled with oil, which he heated to a temperature of 400° R. In the prefaces of Mai's volumes will be found many amusing and interesting facts illustrating the difficulties which attend this curious branch of literary labor.

PA' LINDROME (Gr. *palin*, backwards, and *dromos*, a running), the name given to a kind of verse very common in Latin, the peculiarity of which is that it may be read the same backwards as forwards. A few examples will suffice.

Si bene te tua laus taceat sua laute tenebis.
Et necat eger amor non Roma rege tacente,
Roma reges una non unus eger amor.

A Roman lawyer gets the credit of the following :

Si nummi immunis,

which Camden translates :

'Give me my fee, and I warrant you free.'

It is said that in the reign of Queen Elizabeth a certain lady of rank, having been compelled to retire from the court on account of some *fama*, the truth of which she denied, took for her motto :

Ablata at alba.
'Retired but pure.'

The English language has few palindromes, but one at least is inimitable. It represents our first parent politely introducing himself to Eve in these words :

'Madam, I'm Adam.'

Compare Henry B. Wheatley's book on *Anagrams* (1862).

PALINGENE'SIA (Gr. *palin*, again, and *genesis*, birth) is a term that appears to have originated among the Stoics, who employed it to denote the act of the Demiurgus, or Creator, by which, having absorbed all being into himself, he reproduced it in a new creation. The occurrence of the word in the New Testament (Titus iii. 5, where it is used to denote regeneration) has given it a place in Christian theology, and divines have variously used it to express the resurrection of men, the new birth of the individual soul, and the restoration of the world to that perfect state that it lost by the Fall—the new heavens and the new earth wherein dwelleth righteousness. Savans have also applied the term to designate both the great geological changes which the earth has undergone, and the transformations in the insect kingdom, such as of caterpillars into butterflies, &c.

PA' LINODE, in the law of Scotland, is a peculiar practice by which, in actions for damages on account of slander or defamation raised in the Commissary Court, and even in the Sheriff Court, the pursuer may conclude not only for damages but for

palinode, i. e., a solemn recantation. On a recent case, the question arose whether this ancient practice still existed as part of the law of Scotland, and it was held that it did. In actions, however, in the Court of Session, damages only are given as the remedy.

PALISADE, a paling of strong timber, used in Fortification. For the mode in which the palisade is employed see **FORTIFICATION**, under the head *Stockade*.

PALISANDER WOOD, the continental name for Rosewood (q. v.). By some of the French cabinet-makers the name *bois de Palisandre* is also applied to violet wood and to a kind of striped ebony.

PALISSY, BERNARD, a French potter, famous for his glass paintings and beautiful figured pottery, was born near Agen, now in the department of Lot et Garonne, France, about 1510, and at an early age was apprenticed to a potter. He devoted himself to chemical researches for the improvement of his art, and made many journeys through France and Germany for the same purpose; at the same time carrying on the business of a land-surveyor. An enamelled cup of 'Faience,' which he saw by chance, inspired him with the resolution to discover the mode of producing white enamel. Neglecting all other labors, he devoted himself to investigations and experiments for the long period of 16 years. He had by this time exhausted all his resources, and for want of money to buy fuel was reduced to the necessity of burning his household furniture piece by piece; his neighbors laughed at him, his wife overwhelmed him with reproaches, and his starving family surrounded him crying for food; but in spite of all these discouragements he persisted in the search, and was in the end rewarded by success. A few vessels adorned with figures of animals, colored to represent nature, sold for high prices, and enabled him to complete his investigations, after which he became famous; and though a Huguenot, was protected and encouraged by the king and the nobility, who employed him to embellish their mansions with specimens of his art. He was lodged in or near the Tuileries, and was specially exempted by Queen Catharine from the massacre of St. Bartholomew, more from a regard to her own benefit than from kindness.

In March 1575 he commenced a course of lectures on natural history and physics, and was the first in France to substitute positive facts and rigorous demonstrations for the fanciful interpretations of philosophers. In the course of these lectures, he gave (1584) the first right notions of the origin of springs, and the formation of stones and fossil shells, and strongly advocated the importance of marl as a fertilizing agent. These, along with his theories regarding the best means of purifying water, have been fully supported by recent discovery and investigation. In 1588 he was arrested and thrown into the Bastille as a heretic, but died in 1590 before his sentence was pronounced.

P. left a collection of objects of natural history, the first that had been formed in France. His works are at the present day almost beyond price, and his ornaments and arabesques are amongst the most beautiful of the 'renaissance.' As a sincere, earnest, and courageous man, he was no less eminent than as an artist. See Morley's *Palissy the Potter*.

PALIURUS, a genus of trees and shrubs of the natural order *Rhamnaceæ*, nearly allied to *Zizyphus* (see **JUBBE**), but very different in the fruit, which is dry, orbicular, and girded with a broad membranous wing. *P. aculeatus* is often called **CHRIST'S**

Christ's Thorn (*Paliurus aculeatus*):
a, ripe fruit.

THORN, and by the Germans, **JEWS' THORN** (*Judendorn*), from an imagination that it supplied the crown of thorns with which

our Saviour was crowned. It is a deciduous shrub or low tree, with slender, piliant branches and ovate 3-nerved leaves, each of which has two sharp spines at the base, one straight and the other re-curved. It is a native of the countries around the Mediterranean, of India, and many parts of Asia. It is often used for hedges in Italy and other countries; its sharp spines and piliant branches admirably adapting it for this purpose.

The fruit has a singular appearance, being flat and thin, attached by the middle to the foot-stalk, the middle being raised like the crown of a hat, whilst the expansion resembles the brim. The seeds are sold by the druggists of the east, and are used medicinally, but their qualities are doubtful. This shrub is not uncommon in shrubberies in England, being very ornamental when in flower, but the fruit does not ripen.

PALK STRAIT, or **PALK'S PASSAGE**, the northern portion of the passage between the south coast of Hindustan and the island of Ceylon. This passage is continued southward by the Gulf of Manaar (q. v.). It is from 40 to 80 miles in width, and is 80 miles in length. It is so shallow—in some places being no more than two fathoms in depth—that it cannot be navigated in safety by large vessels. In P. S. there are several pearl fisheries.

PALL (Lat. *pallium*, also *palla*, a cloak), the name given in English to two very different portions of the vesture employed in the religious use of the Roman and some other churches. One of these is the *funeral pall*, an ample covering of black velvet or other stuff, which is cast over the coffin while being borne to burial. The ends of the pall are held during the funeral procession by the most distinguished among the friends of the deceased, generally selected from among those unconnected by blood. In its second and most strictly liturgical use, the word pall is applied to one of the coverings used at the altar in the celebration of the mass. Primatively, as appears from Optatus and other early writers, the altar was covered with a large linen cloth—called by the Latins *pallium*, and by the Greeks *eileton*—the extremities of which were folded back so as to cover the bread and wine prepared for the celebration of the eucharist. In later times a separate covering was employed for the sacramental chalice, to which latter the name pall is now reserved in the use of the Roman Church.

The modern Roman pall is a square piece of linen cloth—sometimes limber, sometimes made stiff by inserting pasteboard—sufficiently large to cover the mouth of the chalice. The upper surface is often of silk embroidered, or of cloth of gold. The surface in contact with the chalice must always be of linen.

PALL, in Heraldry, the upper part of a saltire conjoined to the lower part of a pale. It appears much in the arms of ecclesiastical sees.

PALL-MALL. See **MALL**.

PALLADIO, ANDREA, a famous Italian architect, was born at Vicenza, 30th November 1518. After having studied with the greatest care the writings of Vitruvius, and the monuments of antiquity at Rome, he settled in his native city, and first acquired a reputation by his restoration of the Basilica of Vicenza. Pope Paul III. then invited him to Rome, designing to intrust him with the execution of the works then going on at St. Peter's, but his holiness dying before the arrival of P., the latter had to return home. He was employed for many years in the construction of numerous buildings in Vicenza and the neighborhood, in all of which he displayed the most exquisite taste combined with the most ingenious and imaginative ornamentation. His style, known as the Palladian, is a composite, and is characterized by great splendor of execution and justness of proportion, and it exercised an immense influence on the architecture of Northern Italy. His principal works are the Rotonda Capra, outside Vicenza; the Palazzo Chiericaco and the Palazzo Tiene, in the city; the Palazzo Barbara, at Maser in the Trevigiano, the Teatro Olimpico at Vicenza (his last work), the Palazzo at Montagnana for Francesco Pisana; the churches of San Giorgio Maggiore and Il Santissimo Redemptore at Venice, the atrium and cloister at the convent Della Carità, and the façade of San Francesco della Vigna in the same city. P. died at Vicenza, August 6, 1580. He wrote a work on architecture, which is highly prized. The best edition is that published at Vicenza in 4 vols., 1776.

PALLADIUM (symp. Pd, eq. 53—new system, 106—spe. grav. 11·8) is one of the so-called noble metals, which in its color and ductility closely resembles platinum. It is not fusible in an ordinary wind-furnace, but melts at a somewhat lower temperature than the last-named metal; and when heated beyond its fusing-point, it volatilizes in the form of a green vapor. It undergoes no change in the open air at ordinary temperatures; but at a low red heat, it becomes covered with a purple film, owing to superficial oxidation. It is soluble in nitric and iodic acids, and in aqua regia. It combines readily with gold, which it has the property of rendering brittle and white. (When it forms 20 per cent.

Pall.

of the mass, the alloy is perfectly white.) When alloyed with twice its weight of silver, it forms a ductile compound, which has been employed for the construction of small weights; but for this purpose aluminium is superior. Professor Miller states that it 'has been applied in a few cases to the construction of graduated scales for astronomical instruments, for which, by its whiteness, hardness, and unalterability in the air, it is well adapted;' its scarcity must, however, prevent its general use for this purpose.

It was discovered in 1803 by Wollaston in the ore of platinum, of which it seldom forms so much as 1 per cent. Another source of this metal is the native alloy which it forms with gold in certain mines in Brazil, and which is termed *ouro poudre*; and it is from this alloy that the metal is chiefly obtained.

Palladium forms with oxygen a protoxide, PdO , which is the base of the salts of the metal; a binoxide, PdO_2 ; and according to some chemists, a suboxide, Pd_2O . On exposure to sufficient heat, these compounds give off their oxygen, and yield the metal. The salt of the protoxide are of a brown or red color.

PALLADIUM, among the ancient Greeks and Romans, an image of Pallas, who was generally identified with Athene, upon the careful keeping of which in a sanctuary the public welfare was believed to depend. The Palladium of Troy is particularly celebrated. According to the current myth, it was thrown down from heaven by Zeus, and fell on the plain of Troy, where it was picked up by Ilus, the founder of that city, as a favorable omen. In the course of time, the belief spread that the loss of it would be followed by the fall of the city; it was therefore stolen by Odysseus and Diomedes. Several cities afterwards boasted of possessing it, particularly Argos and Athens. Other accounts, however, affirm that it was not stolen by the Greek chiefs, but carried to Italy by Æneas; and the Romans said that it was preserved in the temple of Vesta, but so secretly, that even the Pontifex Maximus might not behold it. All images of this name were somewhat coarsely hewn out of wood.

PALLA'DIUS, RUTILIUS TAURUS ÆMILIANUS, a Roman author, who probably lived in the 4th c. A.D., under Valentinian and Theodosius. He wrote a work, *De Re Rustica* (On Agriculture), in 14 books, the last of which is a poem of 85 elegiac couplets. It is, from a literary and grammatical point of view, full of faults; but as it was a complete calendar of Roman agriculture, it was very useful for its time, and was much read and followed during the middle ages. P. has borrowed largely from his predecessors. The best edition is that by J. G. Schneider in his *Scriptores Rei Rusticæ Veteres Latini* (4 vols., Leip. 1794).

PA'LLAS. See MINERVA.

PALLAS, PETER SIMON, an eminent traveler and naturalist, was born 23d September 1741, at Berlin, where his father was a physician. He studied medicine, natural history, and other branches of science, at the universities of Berlin, Göttingen, and Leyden, and was employed in classifying many valuable collections of objects of natural history, both in Holland and England. He gained a high reputation by the publication of his *Blensch Zoophytorum* (Hague, 1766), a work still much valued; *Miscellanea Zoologica* (Hague, 1766), and *Spicilegia Zoologica* (2 vols., Berlin, 1767—1804). The Empress Catharine invited him in 1768, to St. Petersburg, where he was well received, and had honors conferred on him, and he was subsequently appointed naturalist to a scientific expedition bound for Siberia, there to observe the transit of Venus. P. spent six years on this journey (1768—1774), exploring in succession the Ural Mountains, the Kirghis Steppes, great part of the Altaian range, and the country around Lake Baikal as far as Kiachta, great part of Siberia, and the steppes of the Volga, returning to St. Petersburg in 1774, with an extraordinary treasure of specimens in natural history, which form the nucleus of the Museum of the Academy of St. Petersburg. His travels (*Reisen durch verschiedene Provinzen des Russ. Reichs*) were published at St. Petersburg (1771—1776), in three volumes, and were followed by his *Sammlung historischer Nachrichten über die Mongol. Völkerschaften* (2 vols., St. Petersburg. 1776—1802), and his *Neue nordische Beiträge zur physikalischen und geographischen Erd- und Völkerbeschreibung, Naturgeschichte und Oekonomie* (6 vols., St. Petersburg. 1781—1793). Without positively neglecting any branch of natural history, he now devoted himself more particularly to botany; and his magnificent *Flora Rossica* (St. Petersburg. 1784—1788), a work which, however, he was not able to complete, and his *Species Astragalorum* (14 parts, Leip. 1800—1804), were among the results of his studies. He published also *Icones Insectorum præcipue Rossia Sibirique Peculiarium* (Erlangen, 1781, 1783, and 1806); and contributed to a glossary of all the languages of the Russian empire, which was published at St. Petersburg.

As he wished to live in the Crimea, the Empress Catharine presented him with an estate in the finest part of that peninsula, where he resided generally from 1796. His *Travels in the South of Russia* were published in 1799 (2 vols., Leip., with volume of

plates). After the death of his wife, he went to Berlin, where he died, 8th September 1811. A large and valuable work of his, on the Fauna of Russia, has not yet been published.

PALLAVICINO, PIETRO SFORZA, an Italian historian, son of the Marquis Alessandro Pallavicino of Parma, was born at Rome, 20th November 1607. Much to the disgust of his father, he took priests' orders, and held several important ecclesiastical appointments during the pontificate of Urban VIII. In 1637, he became a member of the Jesuit Society, and was created a cardinal in 1657 by Pope Alexander VII. He died at Rome, 5th June 1667. P. was a fine scholar, and often presided in the famous Roman academy of the *Umoristi*. The best known of all his writings is his *Istoria del Concilio di Trento* (Rome, 1656—1657), intended as a reply to the still more celebrated and liberal, although, by Catholics, deeply suspected, work of Paul Sarpi. Among his other works may be mentioned *Vindicationes Soc. Jes.* (Rome, 1649); *Arte della Perfezione Cristiana—I Fasti Sacri* (The unpublished MS. is in the library of Parma); *Ermengilda*, a tragedy (Rome, 1644); *Gli Avvertimenti Grammaticali* (Rome, 1661); *Trattato dello Stilo e del Dialogo* (Rome, 1662), and *Lettere* (Rome, 1668).

PA'LLI, a town of Rajputana, in Judpore, stands on the right bank of a branch of the Luni River, in lat. 25° 48' N., long. 73° 24' E. It is an entrepôt for the opium sent from Malwa to Bombay, and is the seat of extensive commerce. It imports European manufactured goods extensively, and is estimated to contain about 50,000 inhabitants.

PALLIOBRANCHIA'TA. See BRANCHIOPODA.

PA'LLIUM, the name given in the Roman Catholic Church to one of the ecclesiastical ornaments worn by the pope, by patriarchs, and by Archbishops. Its use is held by Roman Catholics to descend from a very early period. It is worn by the pope at all times, as a symbol of his reputed universal and abiding jurisdiction. By archbishops it cannot be worn until it has been solemnly asked for and granted by the pope, and even then only during the solemn service of the great church festivals, and on occasions of the ordination of bishops or of priests, and other similar acts of the archiepiscopal order. The pallium is a narrow annular band of white woollen web, about three inches wide, upon which black crosses are embroidered, which encircle the neck of the archbishop, and from which two narrow bands of the same material depend, one falling over the breast, the other over the back of the wearer. Its material is the subject of much care and ceremonial. It is made wholly or in part from the wool of two lambs, which are blessed annually on the festival, and in the church of St. Agnes. During the night of the vigil of the feast of St. Peter and St. Paul, the *pallia* made of this wool are placed on the altar above the tomb of these apostles, and on the feast of St. Peter and St. Paul are delivered by the pope to the subdeacon, whose duty it is to keep them in charge. Within three months of his consecration, every new archbishop is obliged to apply to the pope, in person or by proxy, for the pallium; nor is it lawful for him, until he shall have received it, to exercise any act of what is properly archiepiscopal, as contradistinguished from episcopal jurisdiction. Thus, he cannot, for example call a *provincial* synod. The pallium cannot be transferred from one archbishop to another, but must be received direct from the pope. On the archbishop's death, his pallium is interred with him. Its use is held to symbolize the office of the 'good shepherd' bearing the lost sheep on his shoulders, and is connected by some writers with the vesture of the Jewish high-priest in Exod. xxviii. 4. In the medieval church, the granting of the pallium to archbishops was one of the chief occasions of the tribute which was paid by the national churches to the support of the great central office and dignity of the papacy. In some sees, as, for instance, those of the great prince-bishops of the Rhine, the tribute was as much as 20,000 florins. Roman Catholics, however, maintain that this tribute was not a *payment* for the pallium, but an *offering* to the holy see, made on occasion of the grant of that emblem of jurisdiction.

PALM, a measure of length, originally taken from the width of the hand, measured across the joints of the four fingers. In Greece, it was known as *palaiste*, and was reckoned at three inches, or 1-6 of a cubit, which was their standard unit. The Romans adopted two measures of this name—the one was the Greek *palaiste*, and was called *palmus minor*; the other, which was not introduced till later times, was called *palmus major*, or *palm*, and was taken from the *length* of the hand, being therefore usually estimated at three times the length of the other. At the present day, this measure varies in a most arbitrary manner, being different in each country, and occasionally varying in the same. The English palm, when used at all, which is seldom, is considered to be the fourth part of an English foot, or 3 inches.

The following is a list of the most common measures to which the name palm is given :

	Value in Eng. inches.
Greek <i>palaiste</i>	= 3·08375
Roman <i>palmus</i> , or lesser palm.....	= 2·9124
“ <i>palmā</i> , or greater palm.....	= 3·7372
English palm (½ of a foot).....	= 3·0000
Hamburg palm (¾ of a foot).....	= 3·7633
Amsterdam ‘round’ palm.....	= 4·1200
“ ‘diameter’ palm.....	= 11·9687
Belgian palm, } properly the <i>decimètre</i> =	8·9371
Lombard palm, }	
Spanish palm, or <i>palmā major</i>	= 8·3450
“ or <i>palmā minor</i>	= 2·7817
Portuguese palm, or <i>palmā de Craveira</i>	= 8·6616

In Germany and the Low Countries, the palm is generally confined to wood-measurement, while in Portugal it is used to be the standard of linear measure.

PALM, JOHANN PHILIPP, a bookseller of Nuremberg, who has acquired an historic celebrity as the victim of Napoleonic justice in Germany. He was born at Schorndorf in 1766, and succeeded his father-in-law, Stein, as a bookseller in Nuremberg, the old name of the firm being retained. In the spring of 1806, a pamphlet, entitled *Deutschland in seiner tiefsten Erniedrigung* (Germany in its Deepest Humiliation), which contained some bitter truth concerning Napoleon, and concerning the conduct of the French troops in Bavaria, was sent by this firm to a bookseller in Augsburg in the ordinary course of trade, and, as P. to the last moment of his life averred, without any regard, on his part, to its contents. Napoleon's police traced it to the shop in Nuremberg, and an investigation was ordered, from which nothing resulted. Palm was in Munich, and perhaps escaped imprisonment there because his name was not the same with that of the firm; but supposing all safe, he returned to Nuremberg, and was there taken prisoner, and examined before Marshal Bernadotte, whose adjutant represented his arrestment as the consequence of direct orders from Paris. An extraordinary court-martial, held at Brunnau, to which he was removed, condemned him to death, without, any advocate being heard in his defence. All intercession on his behalf was in vain. General St. Hilaire declared that the orders of the emperor were positive; and the sentence was executed at two o'clock on the same day on which it was pronounced. Subscriptions were raised for the family at St. Petersburg, to which the Emperor and Empress of Russia personally contributed; in England, and in several German towns, as Berlin, Leipzig, Dresden, and Hamburg. Some French writers have endeavored to throw the blame of this murder on Marshal Berthier, instead of Napoleon.

PALM OIL. See **OIL PALM**.

PALM SUNDAY (Lat. *Dominica Palmarum*, or *Dom. in Palmis*), the last Sunday of Lent, is so called from the custom of blessing branches of the palm tree, or of other trees substituted in those countries in which palm cannot be procured, and of carrying the blessed branches in procession, in commemoration of the triumphal entry of our Lord into Jerusalem (John xii). The date of the origin of this custom is uncertain. The first writer in the West who expressly refers to it is Venerable Bede. The usage certainly existed in the 7th century. A special service is found in the Roman missal, and also in the Greek euchologies, for the blessing of ‘branches of palms and olives;’ but in many countries, other trees, as in England, the yew or the willow, and in Brittany, the box, are blessed instead. A procession is formed, the members of which issue from the church carrying branches in their hands, and singing a hymn suited to the occasion, of very ancient origin. In the Greek Church, the book of the Gospels is borne in front. In some of the Catholic countries of the West, a priest, or occasionally, a lay figure, was led at the head, mounted upon an ass, in commemoration of our Lord's entry into the city—a usage which still exists in Spain and in Spanish America. Before their return to the church, the doors have been closed, and certain trophies of the hymn are sung alternately by a choir within the church and by the procession without, when, on the sub-deacon's knocking at the door, it is again thrown open, and the procession re-enters. During the singing of the Passion in the solemn mass which ensues, the congregation hold the palm branch in their hands, and at the conclusion of the service it is carried home to their respective houses, where it is preserved during the year. At Rome, the Procession of the Palms, in which the pope is carried, is among the most striking of the picturesque ceremonies of the Holy Week. In England, Palm Sunday anciently was celebrated with much ceremonial; but the blessing and procession of the palms was discontinued in the Church of England, together with the other ceremonies abolished in the reign of Edward VI.

PA'LMA. See **CANARIES**.

PALMA, the capital of the island of Majorca (q. v.) and of the province of Baleares, is situated on the south-west coast of the island, on the Gulf of Parma, which, between Capes Figuera and Blanco, is 18 miles long, and sweeps 12 miles inland. The city is surrounded by orange plantations, and is walled and fortified. The houses, some of which are built of marble, are mostly in the Moorish style of architecture, and a number of the streets are wide and regular. It is the see of a bishop, and contains a Gothic cathedral, simple but beautiful in style, and with a spire which, from the delicate and airy character of its construction, is called the Angel's Tower. Besides other ecclesiastical edifices, the town contains an Exchange—a beautiful and ornate structure in Germano-Gothic—the governor's palace, an academy of medicine and surgery, and a large number of excellent educational institutions, including three *colegios*. In the port, a mole, 500 yards in length, runs out from the bastions facing the south; and on each side of it are ship-building yards, for the construction of the swift lateen vessels so well known in the Mediterranean. The port is small. The first railway in Majorca was opened from P. to Inca in 1875. Wool, silk, and the cordage for the Spanish navy are manufactured. Though one of the chief marts of Europe in the 18th c., P. now carries on but little commerce. Pop. 50,000.

PA'LMA, or **PALMA DI MONTECHIARO**, a town of Sicily, in the province of Girgenti, 14 miles south-east of the town of Girgenti, near the south-west coast. It is entirely a modern town, its foundation dating only from 1637. There is a trade in almonds, dried fruits, soda, wine, and sulphur. Pop. (1871) 13,458.

PA'LMA CHRISTL. See **CASTOR-OIL PLANT**.

PALMBLAD, VILHELM FREDRICK, a Swedish writer of considerable merit, and one of the earliest and most zealous promoters of the literature of his native country, was born in 1788 at Liljested, in East Gotland, where his father held a post under the government. While still a student at Upsala, P. purchased, in 1810, the university printing-press, and immediately entered upon the publication of several literary and scientific periodicals, which, being the first of the kind that had ever appeared in the Swedish language, attracted considerable notice, and by their intrinsic merit, contributed materially to the diffusion of general information and the creation of a taste for learning among the general Swedish public. The earliest of these were the *Phosphoros*, a mixed literary journal; the *Poetisk Kalender*, an annual; and the *Soenska Litteratur Tidning*, a literary review, which lasted till 1824. The Swedish writers Atterbom and Hammarskjöld were associated with P. in the management of these journals, and, like him, directed all their efforts to supplant the pseudo-classical school of literature, in favor of the romantic style, and to counteract the false French taste of that period, which, under Gustavus III., had been universally followed in Swedish literature and art. P. successively occupied the chairs of History and Geography and of Greek Literature in the university of Upsala; and at his death in 1852, he left the character of having been one of the most industrious and influential Swedish writers of his day. His principal works are—*Minnestafsla öfver Sveriges Regenter* (1831); *Lärobok i nyare Historien* (Ups. 1832); *Handbok i fysiska och politiska Geographien* (1837); *Lärobok i Geographien* (Örebro, 1847); *Grekisk Formkunskap* (Ups. 1848); and in addition to these purely instructive works, among his various novels we may instance his *Familjen Falkenskörd* (Öreb. 1844); *Aurora Käningsmark* (Öreb. 1846), which rank among the best of their class in Swedish literature. P. was the editor of the great Swedish biography, *Namn-kunnige Svenska Män* (Stock. 1835–1852); and besides being an active coadjutor in the direction of the Swedish Literary Society, for which he wrote numerous papers, he was an active contributor to various German works of celebrity, as Ersch and Gruber's *Allgemeine Encyclopädie*, the *Conversations-Lexicon*, &c.

PA'LMÉ, or **PALMI**, a royal city of South Italy, in the province of Reggio-Calabria, 20 miles north-north-east of Reggio, on the coast of the Bay of Gioja. The town, by means of its port, carries on an active trade. Pop. 13,600.

PALMELLA 'CEÆ, a family or group of *Alga*, of the order or sub-order *Conferaceæ*. In organization, they are among the lowest of plants; they are, however, universally regarded as vegetable, and do not, like the *Diatomaceæ*, occupy a somewhat doubtful position between the animal and vegetable kingdoms. The P. all grow on damp surfaces, but some under the influence of fresh water, and some of salt. Some appear as a mere powdery layer, the granules of which have little adherence to each other, as Red Snow (q. v.); some of them assume the form of a slimy film or gelatinous mass, as Gory Dew (q. v.); and some are more firm and membranous, so as to have something of the character of a frond. The P. bear so great a resemblance to the early stages of plants higher in organization, that doubts are entertained of their right to a distinct place in the botanical system, particularly as their mode of reproduction is not yet well understood. Con-

jugation has been observed in some of them. They propagate with great rapidity by gemmation, or something like it, some of them sending forth tubular filaments from their cells, the extremities of which dilate into new cells, after which the connecting tube closes, and ceases to exist; whilst in others the multiplication of cells takes place by division or segmentation (see MONAD), and the young plants exhibit remarkable powers of motion for a short time, like zoospores, being furnished with vibratile cilia, by which their motion is produced. Ere long, however, their motion ceases, and the process of segmentation is ready to begin anew. The motile organs and powers of some of the P. in the earlier part of their existence, have led to their being mistaken for animalcules.

PALMER (Lat. *palmifer*, a palm-bearer), the name of one of those numerous classes of **PILGRIMS** (q. v.), whose origin and history form one of the most interesting studies in the social life of mediæval Europe. The Palmer, properly so called, was a pilgrim who *had performed* the pilgrimage to the **HOLY SEPULCHRE** (q. v.), and had returned, or was returning home after the fulfilment of his vow. The Palmers were so called from their carrying branches of the oriental palm, in token of their accomplished expedition. On arriving at their home, they repaired to the church to return thanks to God, and offered the palm to the priest, to be placed upon the altar. The palms so offered were frequently used in the procession of Palm Sunday. Even after the time of his return, the religious character of the Palmer still continued; and although his office might be supposed to have ceased with the fulfilment of his vow, many Palmers continued their religious peregrinations even in their native country. They were thus a class of itinerant monks, without a fixed residence, professing voluntary poverty, observing celibacy, and visiting at stated times the most remarkable **SANCTUARIES** (q. v.) of the several countries of the West. Their costume was commonly the same as that of the ordinary **PILGRIM** (q. v.), although modified in different countries.

PALMERSTON, VISCOUNT, HENRY JOHN TEMPLE, an English politician, was born at the family mansion, Broadlands, near Romsey, Hants, October 20, 1784. The Temples are of Saxon origin, and the family claim descent from Edwyn, who was deprived of the earldom of Mercia by the Conqueror, and lost his life in defending himself against the Normans in 1071. Sir W. Temple, the diplomatist and patron of Swift, was a member of this family, which removed to Ireland in the time of Elizabeth. The family was ennobled in 1722, when Henry Temple was created a peer of Ireland with the dignities of Baron Temple and Viscount Palmerston. His grandson, the second viscount, father of the famous peer, superintended his son's education at Broadlands, and then sent him to Harrow. P. afterwards went to the university of Edinburgh, where he attended the prelections of Dugald Stewart and other professors. He next matriculated at St. John's College, Cambridge, whence he was summoned to attend the deathbed of his father, on whose decease, in 1805, P. succeeded to the title. His eminent abilities were early recognized, for he was scarcely of age when the Tory party in the university selected him (1806) as their candidate to succeed Mr. Pitt in the representation. The late Marquis of Lansdowne was the Whig candidate; and Lord Byron, then at Cambridge, in his *Hours of Idleness*, evinces the interest he took in the election. P. was unsuccessful, and again in 1807. He entered parliament, however, in the same year for the borough of Newport, his colleague being Arthur Wellesley, then chief secretary of Ireland. In 1811, he exchanged Newport for the university of Cambridge, enjoyed the distinction of representing his *alma mater* for 20 years, and only lost his seat when he became a member of the Grey administration, and supported the Reform Bill. For the last two years of the unreformed parliament, he sat for the now extinct borough of Bletchingly.

At the first election after the Reform Act, he was returned for South Hampshire, but lost his seat at the general election of 1835. He immediately afterwards found a seat for the borough of Tiverton, which he promised never to leave as long as the electors would permit him to represent them. Having traced his representative, we now turn to his official career. P. entered life as a member of the Tory party, and accepted the office of Secretary at War in the Duke of Portland's administration in 1809. This office he held during the successive governments of Mr. Perceval, the Earl of Liverpool, Mr. Canning, Lord Goderich, and the Duke of Wellington—a period extending from 1809 to 1828. There was ample scope at the War-office for P.'s administrative talents and activity. Our military system swarmed with abuses, and the labor thrown upon the Secretary at War during the Peninsular campaigns was prodigious. In 1817, an attempt was made to assassinate P. by an insane army-lieutenant, named Davis, who fired a pistol at him as he was entering the Horse Guards, the bullet, however, only inflicting a slight wound. P. early attached himself to the Canning section of the Liverpool administration, and

he accepted a seat in the cabinet of Mr. Canning. His official connection with the Tory party ceased in 1828, when the 'Great Duke' insisted on accepting Mr. Huskisson's resignation, which was followed by P.'s retirement. The Duke's government was swept away in the reform flood of 1830; and Earl Grey, who became Prime Minister, offered the seals of the Foreign Office to Palmerston. The European horizon was so disturbed at this crisis, that a great political authority declared that if an angel from heaven were in the Foreign Office, he could not preserve peace for three months. P. falsified the prediction. Louis Philippe then filled the throne of France; and for the first time on record England and France acted in concert, and without jealousy, under P.'s foreign ministry. He took a leading part in effecting the independence of Belgium, and in establishing the thrones of Queen Isabella of Spain and Queen Maria of Portugal on a constitutional basis.

In 1841, P. went out of office with the Whigs on the question of free trade in corn; but on their return in 1846, he resumed the seals of the Foreign Office. His second foreign administration furnished various subjects of hostile party criticism, among which may be mentioned the civil war in Switzerland, the Spanish marriages, the European revolutions in 1848, the rupture of diplomatic relations between Spain and Great Britain, and finally, the affair of Don Pacifico and the quarrel with Greece. A vote of censure on the foreign policy of the government was, in 1850, carried in the House of Lords on the motion of Lord Stanley (afterwards Earl of Derby). A counter-resolution, approving the foreign policy of the government, was thereupon moved by Mr. Roebuck in the Lower House. The debate lasted four nights. In a speech of five hours' duration—'that speech,' said Sir Robert Peel, 'which made us all so proud of him'—P. entered upon a manly and dignified vindication of his foreign policy and Mr. Roebuck's motion was carried by a majority of 46. In December 1851, the public were startled at the news that P. was no longer a member of the Russell cabinet. He had expressed his approbation of the *coup d'état* of Louis Napoleon, without consulting either the premier or the Queen; and as explanations were refused, her Majesty exercised her constitutional right by dismissing her minister. P. avenged himself as soon as parliament met, by shattering the Russell administration to pieces on a comparatively trifling question regarding the militia. He refused an offer from the Earl of Derby to join the government which he was commissioned to form, but accepted the post of Home Secretary in the coalition administration of the Earl of Aberdeen in 1852. The fall of this government, on Mr. Roebuck's motion for a Sebastopol committee, placed P. in his 71st year in the position of prime minister, to which he was unanimously called by the voice of the nation. He vigorously prosecuted the Russian war until Sebastopol was taken, and peace was made. His government was defeated in March 1857, on Mr. Cobden's motion condemnatory of the Chinese war.

Parliament was dissolved, and P. met the House of Commons with a large majority. But his administration fell in February 1858, upon the Conspiracy Bill, intended to protect the French emperor against the machinations of plotting refugees. A short Conservative administration followed; but in June 1859, P. was again called to the post of First Lord of the Treasury, which he continued to fill up to his death. It was his ambition to be considered the minister of a nation rather than the minister of a political party; and his opponents have been constrained to admit that he held office with more general acceptance than any English minister since the time of the great Lord Chatham. As an orator, he was usually homely and unpretending, but always sensible and practical. He was a dexterous tactician, and a ready, witty, and often brilliant debater. He was popular as a minister, because he was thoroughly English in his ends and aims. Even his robust health, manly bearing, and physical vigor were elements of his popularity, because they were regarded as a glorification of the English sports, which he was never ashamed to patronize. He desired nothing so ardently as to promote the wealth and grandeur of Great Britain, and his national character and national spirit were thoroughly appreciated by his countrymen. He married, in 1839, the widow of the fifth Earl of Cowper, daughter of the first Viscount Melbourne. As he died without issue, and his only brother died unmarried, the title became extinct on P.'s decease, Oct. 18, 1865. See *Life of P.* by Sir Henry Lytton Bulwer (Lord Dalling), continued by Evelyn Ashley.

PALMER-WORM, a name given to many large kinds of grub, the larvæ of coleopterous insects, destructive to vegetable substances of various kinds. It is used in the English version of the Old Testament as the translation of the Hebrew *gasam*, rendered *kampe* by the Septuagint, which modern Hebrew writers and others very generally regard as a kind of locust, although more probably it is either the grub of a coleopterous or the caterpillar of a lepidopterous insect.—See Kitto in *Pictorial Bible*, on Joel i. 4.

Palmer-flies are much used by anglers on the English streams, and are at certain seasons excellent lures for trout, &c.

PALMETTO (*Sabal palmetto*, or *Chamærops palmetto*), a species of palm, a native of maritime parts of North America, as far north as lat. 35°, which is further north than any other American species of palm is found. It attains a height of 40–50 feet, and has a crown of large palmated leaves, the blade from one foot to five feet in length and breadth, and the footstalk long. The flowers are small, greenish, and in long racemes; the fruit black, about as long as a pea-pod, and uneatable. The leaves are made into hats. The terminal bud or *cabbage* is eaten. The wood is extremely porous; but is preferred to every other kind of wood in North America for wharfs, as it is very durable, and not liable to be attacked by worms.—The *Chamærops* (q. v.) *humilis* of the south of Europe is also called Palmetto.

PALMETTO-LEAVES, the leaves of the Palmyra (q. v.) palm, *Borassus flabelliformis*, which grows extensively in India and Polynesia. The leaves have great value as a material for the manufacture of hats, mats, &c., and for this purpose are frequently imported into Europe. In their native country they are used as thatch, and for a great variety of other useful applications.

PALM-PEDES, or WEB-FOOTED BIRDS, also called **NATORES, or SWIMMERS**, an order of birds, the *Anseres* of Linnaeus, very natural and universally recognized by ornithologists, having the feet specially formed for swimming, and the toes *webbed*, i. e., connected by a membrane, at least those which are directed forwards. In swimming, the feet are contracted when drawn forward, the toes being brought together, and expanded to their utmost extent in the backward stroke. In accordance with their aquatic habits, the P. are further characterized by a boat-like form, calculated to move through the water with little resistance; and by a dense and polished plumage, oiled by a secretion from certain glands near the tail, very impervious to water; whilst warmth is further secured by a clothing of down, more or less abundant, beneath the feathers. They are remarkable for the length of the breast-bone (*sternum*), and the neck is often longer than the legs, a thing very unusual in birds, so that they can plunge the head far down in search of food. The length of the wings differs very much in different sections of the order, and with it the power of flying; as does also the power of diving, which some possess in a high degree, and others, even of the same family, in a very inferior degree. To this order belong geese, swans, ducks, divers, auks, guillemots, puffins, penguins, petrels, albatrosses, gulls, terns, shearwaters, noddies, pelicans, cormorants, frigate-birds, gannets, darters, tropic-birds, &c.

PALMITIC ACID ($\text{HO}, \text{C}_{15}\text{H}_{31}\text{O}_2$) is one of the most important of the *Fatty Acids*, represented by the general formula $\text{HO}, \text{C}_n\text{H}_{2n+1}\text{O}_2$ (see **OILS AND FATS**). In a pure state when crystallized from alcohol, it occurs in the form of beautifully white acicular crystals arranged in tuft-like groups. These crystals are devoid of odor or taste, communicate a fatty feeling to the finger, fuse at 143°.6, and solidify on cooling in the form of crystalline scales. This acid is lighter than water, in which it is perfectly insoluble; but it dissolves freely in boiling alcohol and in ether, and the solutions have a distinctly acid reaction. In small quantities it may be distilled without decomposing, if the heat be carefully regulated. The neutral palmitates of the alkalis constitute soaps, and are soluble in water; if, however, their solutions are largely diluted with additional water, they are decomposed, an insoluble acid salt being precipitated, while a portion of the base remains in solution. The addition of chloride of sodium (common salt) to a solution of an alkaline palmitate produces a similar effect. The other most important compounds of palmitic acid are those which it forms with glycerine and with cetyl ether. With glycerine this acid forms three compounds, viz., a triglyceride or tripalmitate (constituting the ordinary **PALMITINE** of chemists), a diglyceride, and a monoglyceride. In addition to its existence in the form of palmitine, palmitic acid is found in a free state in old palm oil. In combination with cetyl ether, or of oxide of cetyl, whose composition is represented by the formula $\text{C}_{22}\text{H}_{45}\text{O}$, it is the main constituent of *Spermaceti* (q. v.), which is in fact essentially a palmitate of oxide of cetyl— $\text{C}_{22}\text{H}_{45}\text{O}, \text{C}_{15}\text{H}_{31}\text{O}_2$; and, as a palmitate of oxide of melissyl—a substance which will be noticed in the article **WAX**—it is the chief ingredient of bees-wax.

PALMITINE is a white fat, usually occurring, when crystallized from ether, in the form of a mass of small scaly crystals. According to Duffy, it occurs like the allied fat stearine in three modifications, each of which has a different melting-point—viz., 114°·8, 143°, and 145°. On cooling, it solidifies into a wax-like mass, of lower specific gravity than water, and insoluble in that fluid, but readily soluble in ether and in boiling alcohol. It is a constituent of almost every kind of fat, and is the preponderating ingredient in those of a semi-solid consistence, and in many oils. It receives its name from the abundance in which it occurs in

palm oil, and it may readily be obtained from this source by removing the liquid portion (the oleine) by pressure, and purifying the remaining palmitine by crystallization from ether, or a mixture of ether and alcohol. It has been stated in the article on Glycerine (q. v.) that the composition of that substance may be represented by the formula $\text{C}_3\text{H}_5\text{O}_2, 3\text{HO}$. When palmitic acid unites with it to form a triglyceride (or the substance usually recognized as palmitine), three atoms of the anhydrous acid expel and replace the three atoms of water in the glycerine, and the resulting compound, palmitine, is consequently represented by the formula $\text{C}_3\text{H}_5\text{O}_2 + 3(\text{C}_{15}\text{H}_{31}\text{O}_2)$, or $\text{C}_{48}\text{H}_{97}\text{O}_6$.

PALMS (*Palma* or *Palmaceæ*), a natural order of endogenous plants, not excelled in importance by any order in the vegetable kingdom except Grasses. They are generally tall and slender trees, often of gigantic height, without a branch, and bearing at the summit a magnificent and graceful crown of very large leaves. The stem is sometimes, however, of humble growth, and more rarely it is thick in proportion to its height; sometimes, but rarely, it is branched, as in the *Doom* (q. v.) Palm; and sometimes, as in *Rattans* (q. v.), it is flexible, and seeks support from trees and bushes, over which it climbs in jungles and dense forests, clinging to them by means of hooked spines. Some of the species with flexible stem attain a prodigious length, ascending to the tops of the highest trees, and falling down again. Rumphius asserts that they are sometimes 1200, or even 1800 feet long.

Whatever the form or magnitude of the stem of a palm, it is always woody, and the root is always fibrous. It is only towards its circumference, however, that the stem is hard, and there in many species it is extremely hard; but the center is soft, often containing, when young, a great quantity of starch (sago), and sometimes filled, when old, with a mass of fibres which can be separated without difficulty. Concerning the structure of the stem, see **ENDOGENOUS PLANTS**. The stem is generally marked externally with rings or scars, where former leaves have been attached; sometimes it is rough with the remaining bases of the leaves, and part of it is sometimes covered with their fibrous appendages. No other plants have leaves so large as many of the P.; the largest of all are those of some of the fan-leaved P., but there are P. with pinnate leaves 50 feet long and 8 feet broad, and undivided leaves are to be seen 30 feet long by 4 or 5 feet broad. There are, however, also small P., and P. with flexible stems, which have small leaves. The number of the large leaves which form the crown of even the most magnificent palm is never great. Whatever the size or form of the leaves, they are always stalked, the stalk being often in dimensions equal to a large bough of a great oak or other such tree. The leaves are commonly pinnated, the number of pinnules or leaflet being often very great; but about one-sixth of the whole number of known species of P. have fan-shaped leaves, and a few species have undivided leaves. The leaves are in all cases persistent, only falling off in succession as the palm advances in growth, and new ones are formed at the summit. The flowers are sometimes hermaphrodite, sometimes unisexual; the same tree having sometimes male, female, and hermaphrodite flowers, whilst other species are monœcious and others diœcious.

The perianth has six divisions, three outer and three inner; there are generally six, rarely three stamens; the ovary is composed of three carpels, distinct or united, each with one cell containing one ovule. The flowers are small, but are often produced in dense masses of very striking appearance. Humboldt reckons the number of flowers on a single palm (*Alfonsoia amygdalina*) as about 600,000, and every bunch of the *Seje* Palm of the Orinoco consists of about 8000 fruits. The flowers are produced on scaly spadices, often much branched, and enclosed, before expanding, in leathery or woody spathes, often very large, and sometimes opening by bursting with a loud explosion. The flowers of some P. emit a very powerful odor, which attracts multitudes of insects. The fruit is sometimes a kind of berry, sometimes a drupe, either with a fleshy or a fibrous covering; and sometimes contains a very hard and bony nut. The fruit is sometimes only of the size of a pea or a cherry; sometimes, notwithstanding the smallness of the flowers, it is of very large size, of which the cocoa-nut is a familiar example.

Palms are mostly natives of tropical countries, being found almost everywhere within the tropics, and forming, perhaps, the most striking characteristic of tropical vegetation. The tropical parts of America, however, particularly abound in them, producing a far greater number of species than any other part of the world. A few species are found in temperate regions; one species only, *Chamærops humilis*, being a native of Europe, and extending as far north as lat. 44°, whilst the northern limit of P. in Asia is about lat. 34°, and in North America, lat. 35°. In South America, the southern limit of P. is lat. 36°; in Australia, it is lat. 35°; in Africa, no native species is found further south than lat. 30°; but in New Zealand, one species extends as far south as lat. 38° 22'. Some of the species, however, which are found in

tropical America grow in mountain regions bordering upon the limits of perpetual snow.

Some P. have very narrow geographical limits; the cocoa-nut palm is by far the most extensively distributed species. Some, like the cocoa-nut, grow in maritime, others in inland districts. Some grow on dry and sandy ground, others in the richest alluvial soil, and some in swampy situations; some in open districts, others in dense forests. Some species are generally found singly, some in groups; some even cover tracts of country in which no other tree appears.

The uses of P. are many and various; there is almost no species which is not capable of being applied to some use. Tribes in the lowest grade of civilization depend almost entirely on particular species of palm, as the cocoa-nut palm, for the supply of all their wants. The fruit of some species is eaten; sometimes the fleshy part of the fruit, sometimes the kernel of the nut. The importance of the date and the cocoa-nut needs only to be alluded to; but in this respect they far excel the fruits of all other palms. A grateful beverage is made from the fruit of some P. (see ASSAR), consisting simply of a mixture of the pulp with water; but a kind of wine can be obtained also by fermentation (see DATE). A kind of beverage more generally used is the sap of palm-trees, either fresh or fermented (*palm-wine* or *toddy*), from which also a kind of spirits called Arrack (q. v.) is obtained by distillation; whilst from the fresh sap, boiled down, sugar is obtained—the *jaggery* of the East Indies. The sap of various species of palm is collected and used for these purposes, and that of many others is probably not less suitable. The pulp of the fruit of some species, and the kernel of others, yield bland fixed oil useful for various purposes. See OIL PALM and COCOA-NUT. The soft and starchy center of the stem of some P. affords a very important and abundant article of food. See SAGO. The terminal bud, or *cabbage*, of some species is boiled for the table; and although the taking of the bud is death to the tree, this is little regarded where vegetation goes on with a rapidity and luxuriance unknown in the colder parts of the world.

The young sprouts arising from the seeds of P., when they have begun to vegetate, are another esculent of tropical countries. From the stems of some species of palm, as the Wax Palm (q. v.) of the Andes, and from the leaves of some, as the Carnaluba Palm (q. v.), wax is obtained, which is used for the same purposes as bees-wax. The wood of P. is used in house building, and for many other purposes; some affording very hard and beautiful wood for ornamental work, whilst others are suitable only for coarse purposes. The great leaf-stalks are also used for some of the purposes of timber. The stems of the most slender species are used for walking-sticks, &c., and, split or unsplit, for wicker work. See RATTAN. The leaves of many P. are used for thatching houses. The spathes of some species are used as vessels or bags. The fibres of the leaf, the fibres connected with the leaf-stalk, the fibres of the rind of the fruit, and the fibres of the stem of different kinds of P. are used for making cordage, mats, nets, cloths, &c. The most important of these fibres are Coir (q. v.) or Cocoa-nut Fibre, Gomuto (q. v.) or Ejoor Fibre, as Plassaba (q. v.). The coarsest fibres are employed as bristles for making brushes, &c. Stripes of the delicate epidermis of the young unopened leaves of some South American P. are twisted and so used for making a kind of thread; hammocks made of which are highly valued. See ASTROCARYUM. The leaves of the Palmyra Palm and Talipot Palm are used in some parts of the east for writing upon, an iron style being employed instead of a pen. One of the kinds of the resinous substances called *Dragon's Blood* is obtained from the fruit of a palm. The Betel (q. v.) Nut, abounding in Catechu, is the fruit of a palm.

The fruit of many P. is very acid. The ashes of the fruits of some American species are used by the Indians as a substitute for salt, probably on account of potash, or some salt of potash, which they contain; and much potash may be obtained from the stems and leaves of palms. Vegetable Ivory (q. v.) is the kernel of the fruit of a palm; and somewhat similar to it in quality is the Coquilla Nut (q. v.). But a complete enumeration of the uses to which P. and their products are applied is almost impossible.

Some of the more important species of P. are noticed in separate articles.

About five hundred species are known; but it is probable that many are still undescribed. The most complete work on P. is the monograph by Martius, *Genera et Species Palmarum* (3 vols., large folio, Munich, 1833—1845), a magnificent work, with 219 colored plates; but many new species have been discovered since its publication.

The cultivation of P. in hothouses is attended with great expense. Separate houses are devoted to them in a few gardens, of which the greatest is that at Kew. A very fine palm-house has been erected in the Botanic Garden of Edinburgh. P. are cultivated in hothouses merely as objects of interest, and for the gratification of a refined taste, never for the sake of their fruit or any other product.

PALMY'RA, the name given by the Greeks to a great and splendid city of Upper Syria. Its original Hebrew name was *Tadmor*, which, like the Greek word, means 'city of palms.' It was built, according to the writers of Kings (Book I. chap. ix. verse 18) and Chronicles (Book II. chap. viii. verse 4), by Solomon in the 10th c. B.C.; but it is more probable that he only enlarged it. It occupied a fertile oasis, well watered, and abounding in palm-trees. Barren and naked mountains overlook it from the west, and to the east and south stretches the illimitable sandy desert. P. was, in the Solomonic age, a bulwark of the Hebrew kingdom against the wandering hordes of Beduins; but its early history is obscure and insignificant. After the fall of Selucia, it became a great center of commercial intercourse between the east and the west of Asia. Its commercial importance, wealth, and magnificence greatly increased after the time of Trajan, who subjected the whole country to the Roman empire. In the 3d c., Odenathus, a Syrian, founded here an empire, which, after his murder, rose to great prosperity under his wife, Zenobia (q. v.), and included both Syria and Mesopotamia; but this was not of long duration, for the Roman Emperor Aurelian conquered it in the year 275, and the city was soon after almost entirely destroyed in revenge for the slaughter of a Roman garrison. It never recovered from this blow, although Justinian fortified it anew. The Saracens destroyed it in 744. A village called Tadmor, inhabited by a few Arab families, now occupies the site. The ruins of the ancient city, white and dazzling in the Syrian sun, excite at a little distance the admiration of all beholders; but when examined in detail, they are said to be far from imposing, though in regard to this latter point opinions differ. They were visited by English merchants resident at Aleppo in 1691, and again by Messrs. Wood and Dawkins in 1751, and since then by a vast number of travelers. The ruins of a temple of Baal, the sun god, are, however, confessedly magnificent. The language of ancient Palmyrene appears, from inscriptions which remain, to have been an Aramic dialect. See Murray's or Baedeker's *Handbook for Syria and Palestine*; Vogüé's *Syrie Centrale*.

PALMYRA PALM (*Borassus flabelliformis*), a species of palm with a magnificent crown of fan-shaped leaves, a native of the East Indies. The stem attains a height of 25—40, or even 60 feet, and tapers slightly upwards. The leaves are about four feet long, with stalks of about the same length, the stalks spiny at the edges; each leaf having 70—80 rays. The fruit is somewhat triangular, about the size of a child's head; having a thick, fibrous, and rather succulent yellowish-brown or glossy black rind, and containing three seeds each as large as a goose's egg. The P. P. is the most common palm of India, growing spontaneously in many districts, cultivated in others, and reaching as far north as lat. 30°. It is of slow growth; and the wood near the circumference of the stem in old trees is very hard, black, heavy, durable, susceptible of a high polish, and valuable, easily divided in a longitudinal direction, but very difficult to cut across. The P. P. abounds greatly in the north of Ceylon, forming extensive forests; and the timber is exported to the opposite coast of India, being of superior quality to that which is produced there. It is much used in house building. The stalks of the leaves are used for making fences, &c. The leaves are used for thatching houses, for making baskets, mats, hats, umbrellas, and large fans; and for writing upon. Their fibres are employed for making twine and small rope; they are about two feet long, and very wiry. A fine down found at the base of the leaf-stalks is used for straining liquids, and for stanching wounds. The P. P. yields palm-wine, and of course also arrack and sugar (*jaggery*). It furnishes great part of the palm-wine, sugar, and arrack of India. See ARRACK. The fruit is cooked in a great variety of ways, and used for food. The seeds are jelly-like, and palatable when young. A bland fixed oil is extracted from the fruit.

The young plants, when a few inches high, are esteemed as a culinary vegetable, being boiled and eaten generally with a little of the kernel of the cocoa-nut; and sometimes they are dried and pounded into a kind of meal. Multitudes of the inhabitants of the north of Ceylon depend almost entirely on the P. P. for the supply of all their wants. In the 'Palmyra Regions' of the Southern Dekkan vast numbers of the people subsist chiefly on the fruit of this palm.

The Deleb Palm (q. v.), so important to the inhabitants of Central Africa, is believed to be nearly allied to the Palmyra Palm.

PALMYRA WOOD. Properly this name applies only to the wood of the Palmyra palm (*Borassus flabelliformis*), but it is generally used for all kind of palm-tree wood imported into this country, amongst which very much is the wood of the cocoa-nut palm, *Cocos nucifera*, and the allied species *C. plumosa*. These woods are also called *Speckled Wood* and *Porcupine Wood* by the dealers—the former name being applied to those veneers cut transversely, and showing the ends of numerous black fibres mixed with the lighter-colored portions; and the latter to longitudinal

sections, in which the mixed black and white fibres much resemble porcupines' quills.

PA'LO BLA'NCO (*Flotovia dicanthoides*, a large tree, a native of Chili, the wood of which is white, and very useful and durable. It is remarkable as one of the few large trees belonging to the natural order *Compositae*.

PALO'LO, or BALOLO (*Palolo viridis*), a dorsi-branchiate annelid, allied to the Lug-worm, extremely abundant at certain seasons in the sea above and near the coral reefs which surround many of the South Sea Islands, as the Samoa Islands and the Fiji Islands. The body is cylindrical, slightly tapering at both ends, divided into nearly equal joints, each joint with a small tuft of

Palolo Viridis (copied from Seemann's *Vith*):

1, the entire animal, half natural size; 2, portion of body, slightly magnified; 3, magnified figure of its head, with its three frontal tentacula and eyes; 4, posterior extremity, dorsal aspect.

gills on each side. In thickness, the P. resembles a very fine straw; it is about three inches long, generally of a greenish color, with a row of round black spots; but the color varies to red, brown, and white. These annelids make their appearance in great multitudes, apparently rising out of the coral reefs, and with a periodical regularity which is very remarkable. They are eagerly sought after by the islanders, who are on the watch for their appearance, and go out in canoes early in the morning to take them by means of nets; but they often occur in such numbers that the water seems to be full of them, and they may be grasped by handfuls. They are a delicacy of which the South Sea Islanders are very fond. To prepare them for use, they are wrapped in bread-fruit leaves, and cooked for twelve or eighteen hours in an oven.

PA'LPI (from the Lat. *palpo*, I touch) are organs occurring in Insects, Crustaceans, and Arachnidans. In Insects, one or two pair of jointed appendages bearing this name are attached to the maxillæ, while one pair is attached to the labium; and in the higher Crustaceans, similar appendages are attached to the mandibles and foot-jaws. In both these classes, the palpi probably serve, through the sense of touch, to take cognizance of the qualities of the substances which are employed as food. In the Arachnidans, the palpi are attached to the maxillæ only; and vary exceedingly in form and functions. In the scorpions, for instance, they are extremely developed, and terminate in pincers which resemble the chelæ (or pincers) of crabs and lobsters; while in the spiders, they terminate in a single movable claw in the female, and in the male the last joint is dilated, and acts as an accessory generative organ.

PALPITATION is the term used to signify inordinately forcible pulsations of the heart, so as to make themselves felt, and frequently to give rise to a most troublesome and disagreeable sensation. It may be either functional or a symptom of organic disease of the heart. Here we shall merely consider it as a functional disorder. Although it may be persistent, it far more frequently comes on in paroxysms, which usually terminate within half an hour, recurring afterwards quite irregularly, sometimes daily or several times a day, and sometimes not till after a long interval. The attack often comes on under some mental or physical excitement, but sometimes when the patient is quite composed, or even asleep. If the paroxysm is a severe one, the heart feels as if bounding upwards into the throat; and there is a sensation of oppression over the cardiac region, with hurried or even difficult respiration. Excluding organic diseases, the causes of this affection are either (1) an abnormally excitable condition of the nerves of the heart, or (2) an unhealthy condition of the blood.

1. Amongst the causes of disturbed innervation may be especially noticed the abuse of tea (especially green tea), coffee, spirits, and tobacco. Any irritation of the stomach and intestinal canal may be reflected to the heart; and hence palpitation may frequently be traced to flatulence, undue acidity, and intestinal worms, especially tape-worms. Everything that causes pressure on the heart, such as tight lacing, abdominal dropsy, or an enlarged uterus, is also liable to occasion this affection.

2. If the blood is abnormally rich and stimulating it may give rise to palpitation, as in Plethora (q. v.); but the opposite condition, known as Anæmia (q. v.), is a much more common cause of this affection. In anæmia the blood is watery and deficient in fibrine, and (far more) in red corpuscles; and being thus in an unnatural state, it acts as an unnatural stimulant, and induces frequent, although not usually strong pulsations. In cases of this kind, singular murmurs (not unlike those which are heard when we apply certain shells to the ear) are heard on applying the stethoscope to the neck over the course of the great jugular veins.

The age at which palpitation most usually comes on is from 15 to 25 years; and the affection—especially if it arise from anæmia—is very much more common in the female than in the male sex.

The treatment of palpitation must entirely depend upon its cause. The use of all nervous stimulants (tea, coffee, alcohol, and tobacco) should be suspended or abandoned. If the patient is clearly plethoric, with a full strong pulse, he should take saline cathartics, and live upon comparatively low diet (including little animal food) until this condition is removed. When, on the other hand, the palpitation is due to an anæmia condition, the remedies are preparations of iron, aloetic purgatives, an abundance of animal food, bitter ale, the cold shower-bath, and moderate exercise.

PA'LSY. See PARALYSIS.

PAMIR (also aptly called *Bam-i-dunya*, 'Roof of the World'), a mountainous region in Central Asia, forming the nucleus of the Central Asian highland system: Hither converge the Hindu Kush, the Himalaya, the Kuen-lun, and the Tian-Shan Mountains. The P. is not so much a plateau or region of lofty plateaux, as a vast mountainous district some 30,000 square miles in area, broken up into ridges and valleys. The ridges rise from 6000 to 9000 feet above the valleys, and the culminating points attain in some cases the great height of 25,000 feet above sea-level.

PA'MLICO SOUND, on the coast of North Carolina, U.S., is separated from the ocean by long, narrow islands of sand, an angle of the largest forming Cape Hatteras, and connected with the ocean by narrow passages; it is 80 miles long, and from 10 to 30 miles wide, and receives the Neuse and Pamlico Rivers.

PA'MPAS (in the Quichua tongue, 'a valley' or 'plain') is a term frequently employed in a general sense as a designation of Southern American plains, in contradistinction to the 'prairies' of North America. It is also used in Peru as a general designation of tracts of level land either on the coast or among the mountains. The chief pampas in Peru are those of the Sacramento. But in its more special and proper signification, the word pampas is given to the immense and partly undulating plains bounded by the Rio Negro of Patagonia, the La Plata and Paraguay, and the base of the Cordilleras. These plains during the wet season afford abundant pasturage to the many herds of wild oxen and horses which roam over them, but they become rapidly parched under the burning heat of the sun, except in the low-lying tracts, or along the banks of rivers. The most fertile of the pampas lie westwards towards the Cordilleras. From the rapid alternation of vigorous growth with parching drought, the growth of trees is impossible, and their place is accordingly supplied by sparse groups of stunted shrubs. The soil, which is in general poor, is a diluvium composed of sandy clay, and abounds in the bones of extinct mammals. Strips of waterless desert, known as *travesias*, stretch across the pampas; these *travesias* are destitute of all vegetation with the exception of a few bushes, and are markedly distinct in geological character.

The soil of the pampas is more or less impregnated with salt, and saltpetre abounds in many places. The wild animals of the pampas are horses, oxen (both introduced by the Spaniards), hounds, and guanacos. The skins of the horses and oxen, and the flesh of the latter, form a most important item in the trade of this region. The half-white inhabitants of the pampas are called Guachos (q. v.). The whole area of the pampas has been estimated at about 1,500,000 square miles.

PAMPAS GRASS (*Gyntherium argenteum*), a grass which covers the pampas in the south of Brazil and more southern parts of South America, and has been introduced into Britain as an ornamental plant. It is quite hardy, and its tufts have a splendid appearance. The leaves are six or eight feet long, the ends hanging gracefully over; the flowering stems ten to fourteen feet high; the panicles of flowers silvery white, and from eighteen inches to

two feet long. The herbage is too coarse to be of any agricultural value. The male and female flowers are on separate plants; in panicles; the spikelets 2-flowered, one floret stalked, and the other sessile; the paleæ of the female florets elongated, awn-

Pampas Grass (*Gynerium argenteum*).

shaped, and woolly.—Another species of the same genus, *G. saccharoides*, also a Brazilian grass, yields a considerable quantity of sugar.

PAMPELUNA, or PAMPLONA, a fortified city of Spain, capital of Navarre, of which it is the key, occupies an eminence not commanded by any neighboring height, on the left bank of the Arga, a tributary of the Ebro, 111 m. N.N.W. of Zaragoza by railway, and 200 miles north-north-east of Madrid. The citadel, overlooking the river and commanding the plain, is a regular pentagon, each side being 1000 feet in extent, and is connected with the city by an esplanade or glacis. Magnificent views of the Pyrenees on the north are obtained from the citadel, and there are several very pleasant promenades. The *Ouenca* (plain) of P. is about 80 miles in circumference; and although the climate is somewhat chilly and damp, the gardens are fruitful and the meadows verdant. The city is well built and clean; water is brought from hills about nine miles distant, by means of an aqueduct built after the solid Roman style by Ventura Rodriguez, and a portion of which, 2300 feet in length, is supported on 97 arches, 35 feet in span, and 65 feet in height. The town contains a number of squares with fountains, a theater, and a regular *plaza de toros*—bull arena—capable it is said, of containing 10,000 people. Agriculture, the wine trade, and the manufacture of linen and leather, are the only noteworthy branches of industry. P. was blockaded by the Carlists in 1874. Pop. (1877) 25,630.

P. was called by the ancients *Pompeopolis*, from the circumstance of its having been rebuilt by the sons of Pompey in 68 B.C. It was taken by the Goths in 466, by the Franks under Charlebert in 542, and again under Charlemagne in 778. It was subsequently for a time in possession of the Moors, who corrupted the name *Pompeopolis* into *Bambilonah*, whence the modern Pamplona. In later times it was seized by the French in 1808, and held by them till 1813, when it fell into the hands of the allies under the Duke of Wellington.

PA'MPHLET (variously derived from Spanish *papaleta*, slip of paper on which anything is written, and *pagina filata*, threaded page), a small book consisting of a sheet of paper, or a few sheets stitched together, but not bound. It generally contains a short treatise on some subject, political or otherwise, which is exciting public attention at the time of its appearance. The word is of considerable antiquity, as it is to be met with in Chaucer; but it was not till about the middle of the 16th c. that pamphlets began to be of common use in political and religious controversy in England and France. Under the second French empire, political pamphlets appeared from time to time which were generally believed to be written under imperial dictation, and either to speak the sentiments of the emperor, or to be feelers of public opinion.

PAMPHY'LIA, anciently a country on the south coast of Asia Minor, with Cilicia on the east and Lycia on the west. It was originally bounded on the inland or northern side by Mount Taurus, but afterwards enlarged, so as to reach the confines of Phrygia. P. is mountainous, was formerly well wooded, and had numerous maritime cities. The inhabitants—a mixed race of aborigines, Cilicians, and Greek colonists—spoke a language the basis of which was probably Greek, but which was disfigured and corrupted by the infusion of barbaric elements. Their coins show that they had adopted to some extent the religion, arts, and games of the Hellenic race. Its political history is unimportant. Along with Phrygia and Lycia it fell to the share of Antigonos on the partition of the Macedonian empire. It afterwards passed successively into the hands of the Græco-Syrian princes, the kings of Pergamus, and the Romans.

PAN, among the Greeks, the chief god of pastures, forests, and flocks. The later rationalizing mythologists, misconceiving the meaning of his name, which they confounded with *to pan*, 'the whole,' or 'the universe,' whereas it is more probably connected with *pao* (Lat. *pasco*), 'to feed,' 'to pasture,' represented him as a personification of the universe, but there is absolutely nothing in the myth to warrant such a notion. Pan neither in his genius nor his history figures as one of the great principal deities, and his worship became general only at a comparatively late period. He was, according to the most common belief, a son of Hermes (Mercury) by the daughter of Dryops; or by Penelope, the wife of Ulysses; while other accounts make Penelope the mother, but Ulysses himself the father—though the paternity of the god is also ascribed to the numerous wooers of Penelope in common. The original seat of his worship was the wild hilly and wooded solitudes of Arcadia, whence it gradually spread over the rest of Greece, but was not introduced into Athens until after the battle of Marathon. Homer does not mention him. From his very birth his appearance was peculiar. He came into the world with horns, a goat's beard, a crooked nose, pointed ears, a tail, and goat's feet; and so frightened his mother that she ran off for fear, but his father, Hermes, carried him to Olympus, where all the gods, especially Dionysus (Bacchus), were charmed with the little monster. When he grew up he had a grim shaggy aspect, and a terrible voice, which bursting abruptly on the ear of the traveler in solitary places—for Pan was fond of making a great noise—inspired him with a sudden fear (whence the word *panic*). It is even related that the alarm excited by his blowing upon a shell decided the victory of the gods over the Titans. He was the patron of all persons occupied in the care of cattle and of bees, in hunting and in fishing.

During the heat of the day he used to take a nap in the deep woods or on the lonely hillsides, and was exceedingly wroth if his slumber was disturbed by the halloo of the hunters. He is also represented as fond of music, and of dancing with the forest nymphs, and as the inventor of the syrinx or shepherd's flute, also called Pan's pipe. Cows, goats, lambs, milk, honey, and new wine were offered him. The fir-tree was sacred to him, and he had sanctuaries and temples in various parts of Arcadia, at Troezen, at Sicyon, at Athens, &c. The Romans identified the Greek Pan with their own Italian god Inuus, and sometimes also with Faunus. See FAUN.

When, after the establishment of Christianity, the heathen deities were degraded by the church into fallen angels, the characteristics of Pan—viz., the horns, the goat's beard, the pointed ears, the crooked nose, the tail, and the goat's feet—were transferred to the Devil himself, and thus the 'Auld Hornie' of popular superstition is simply Pan in disguise.

PANAMA', a city and seaport of the republic of Colombia, in S. America, capital of the 'state' of the same name, at the head of the Bay of Panama, on the southern shore of the isthmus of the same name, in lat. 8° 56' N., long. 79° 31' W. It occupies a tongue of land which extends some distance out to sea in shallow waters. The harbor is safe, but vessels of more than 80 tons burden cannot approach within two miles of the shore. Large vessels anchor at a distance of three miles, near the island of Perico. The important edifices of the city include a beautiful cathedral, a college, and several convents, all of which, however, are falling into decay. There is considerable trade with Europe in pearls, mother-of-pearl, shells, and gold-dust, obtained in the vicinity. P. is chiefly important, however, as the Pacific terminus of the Panama Railway. This railway was completed in 1855, is about 48 miles in length, and connects P. on the Pacific with Aspinwall colony on the Atlantic. By means of it the route to California was much shortened, and mails were carried over it till the completion of the Pacific Railway. Pop. (1870) 18,378. The former city of P., the seat of the Spanish colonial government established in 1618, stood six miles N.-E. of P., and is now a heap of ruins.

PANAMA, ISTHMUS OF, is that portion of the narrow ridge of mountainous country connecting Central and South America, which is bounded on the W. by the frontier of Costa Rica, and

on the E. by the surveyed inter-oceanic route from the Bay of Caledonia on the N. to the Gulf of San Miguel on the S. or Pacific side. It extends in long. from 77° to 83° W. The 'State' of P., one of those which form the United States of Colombia, is co-extensive with the isthmus of the same name. Area, 29,756. Pop. (1870) 220,542. P. contains the provinces of Panama, Azuero, Chiriqui, and Veraguas. The Isthmus is traversed throughout by a chain of mountains, forming the barrier between the Atlantic and Pacific oceans, and of which the highest peak is that of Pica-cho (7200 feet) in the west. Numerous streams, the largest of which is the Tuira (162 miles long, and navigable for 102 miles), fall into both oceans. On the Pacific shores are numerous beautiful islands, among which Las Perlas, so called from their pearl fisheries, and the island of Coiba, are the chief. On the north coast, the principal harbors are the Chiriqui Lagoon, San Blas, and the Caledonia; on the south shore, Damas in the island of Coiba, the Bay of San Miguel, and Golfo Dulce. Gold, which in ancient times was obtained here in great quantities, is still found, and mines of salt, copper, iron, coal, &c., are worked. The climate is unhealthy, except in the interior and on the flanks of the mountains. Almost all the plants of the torrid zone may be raised here, but maize, rice, plantains, &c. (grown for the purpose of supplying the transit), are the chief crops. The imports amount annually to about £500,000, and the exports to the same value.—In 1855 a railway across the isthmus, from Aspinwall city on the Atlantic to Panama on the Pacific, was opened. The summit of the railway is 250 feet above the level of the sea; and the average value of the goods that annually pass over it is estimated at £11,000,000. The inter-oceanic canal promoted by M. Lesseps, also between Limon or Aspinwall and Panama, is in the main parallel to the railway. It is a level cutting, without locks, the cost being estimated at £33,000,000. Work was begun in 1881. The name, Isthmus of P., is generally used as interchangeable with Isthmus of Darien (q. v.).

PANATHENÆA, the most famous festival of Attica, celebrated at Athens in honor of Athene, patron goddess of the city, and intended to remind the people of Attica of their union into one community by the mythical Theseus. Before the time of Theseus, or—to speak more critically—before the formation of the Attic confederacy, this festival was only for the citizens of Athens, and was called simply *Athenæa*. According to tradition, the Athenæa owed its origin to King Erichthonius about 1506 or 1521 B.C. The later Panathenæa appears to have been a double festival. All writers who mention it, speak of a Lesser and Greater Panathenæa, the former held annually, the latter every fourth year. Both took place in the month *Hecatombeon* (July), and lasted several days. The Lesser Panathenæa was celebrated with gymnastic games, musical competitions, declamations, and a torch race in the evening, the whole concluding with the sacrifices of an ox. The prize of the victors was a vessel filled with oil from the sacred tree on the Acropolis. The greater Panathenæa only differed from the Lesser in being more solemn and magnificent. Rhapsodists sang the Homeric poems; dramatic representations were given; and a splendid procession took place to the temple of Athene Polias, on the last day of the festival, to present the goddess with a *peplos* or embroidered robe, of crocus color, woven by the maidens (*ergastinai*) of the city. Not alone the Athenians, but the whole population of Attica poured forth on this occasion. The procession is grandly sculptured on the frieze of the Parthenon by Phidias and his disciples.

PA'NAX. See GINSENG.

PA'NCAKE. This article of food is prepared by pouring a rich batter of flour, eggs, and milk into a frying-pan, so as to cover it about half an inch in thickness; the pan having been previously heated, and well supplied with butter, lard, or olive oil. A quick fire is necessary to cook it well, and when the under side is done, a dexterous cook by jerking the frying-pan manages to reverse the cake, so as to bring the upper side downward to be cooked in its turn. It is now a common practice to make pancakes rather smaller than the bottom of the pan, and frequently to add minced apples and other materials to vary and flavor them; these are, however, better known under the name of Fritters.

This dish is particularly associated with Shrove Tuesday, but the origin of the connection is by no means clear. Perhaps it is the relic of a heathen custom. The Saxons called February, *Solmonath*, 'which,' says a writer in *Notes and Queries* (First Series, vol. v. p. 491), 'Dr. Frank Sayers, in his *Disquisitions*, says is explained by Bede, *Menſis Placentarum*, and rendered by Spelman, in an inedited MS., "Pancake month," because, in the course of it, pancakes were offered by the pagan Saxons to the sun.'

PANCHATANTRA (literally, the five books) is the name of the celebrated Sanscrit fable-book of the Hindus whence the *Hithopades'a* (q. v.) was compiled and enlarged. Its authorship is ascribed to a Brahman of the name of Vishn'us'arman, who, as its introduction in a later recension relates, had undertaken to

instruct, within six months, the unruly sons of Amaras'akti, a king of Mahilāropya or Mililāropya, in all branches of knowledge required by a king, and for this purpose composed this work. If the latter part of the story be true, it is more probable, however, as Professor Benfey assumes, that Vishn'us'arman was merely the teacher of the princes, and that the existing work itself was composed by some other personage; for an older recension of the work does not speak of his having brought his tales into the shape of a work. The arrangement of the P. is quite similar to that of the *Hithopades'a*. The fables are narrated in prose, and the morals drawn from or connected with them are interwoven with the narrative in verse; many such verses, if not all, being quotations from older works.—On the history of the P., and its relation to the fable-books and fables of other nations, see the excellent work of Professor Theodor Benfey, *Panchatantra; fünf Bücher indischer Fabeln, Märchen und Erzählungen* (3 vols., Leip. 1859), the first volume containing his historical and critical researches on, and the latter his literal translation into German of, the *Panchatantra*.

PANCREAS (from the Gr. *pan*, all, and *kreas*, flesh) is a conglomerate gland, lying transversely across the posterior wall of the abdomen, varying in length from 6 to 8 inches, having a breadth of about an inch and a half, and a thickness of from half

The under surface of the Stomach and Liver which are raised to show the Duodenum and Pancreas:

st, stomach; p, its pyloric end; l, liver; g, gall-bladder; d, duodenum, extending from the pyloric end of the stomach to the front, where the superior mesenteric artery (sm) crosses the intestines; pa, pancreas; sp, spleen; a, abdominal aorta.

an inch to an inch. Its usual weight is about three ounces. The head of the pancreas lies in the concavity of the duodenum.

The secretion of this gland, or the pancreatic fluid, is conveyed from its various parts by means of the pancreatic duct to the duodenum. This gland is found in all mammals, birds, reptiles, amphibians, and osseous fishes, and in some cartilaginous fishes.

The physical and chemical characters of the pancreatic fluid, and its uses in the animal economy, are sufficiently noticed in the article DIGESTION.

The diseases of the pancreas are few, and do not signify their existence by any very marked symptoms. The presence of undigested fat in the stools has been frequently observed in cases in which after death the pancreas has been found to be diseased; and if Bernard's view regarding the saponifying power of the pancreatic juice on fatty matters (described in the article already referred to) be correct, the reason why the fat should appear in the evacuations in these cases is sufficiently obvious. The most common form of disease is cancerous deposit in the head of the gland, which frequently induces jaundice by obstructing the common biliary duct near its opening. An accurate diagnosis of disease of this organ is extremely difficult, but fortunately is of comparatively little importance, as it cannot lead to efficient treatment; all that can be done in these cases being to palliate the most distressing symptoms.

The pancreas of ruminating animals is a favorite article of food under the name of sweetbread. That of the calf is most highly esteemed, but that of the lamb is often substituted for it. Dr. Edward Smith questions whether the very high price often paid for calf's sweetbread is warranted by its nutritive qualities, or even by its flavor; although he allows that the flavor is perhaps the most delicate of any meat we are acquainted with. It is either boiled or fried. The thyroid and sublingual glands are also used as sweetbread.

PANCSOVA, an active trading town in the south of Hungary, inhabited by Servians and Germans, 70 miles S.S.W. of Temesvar, and close to the mouth of the Temes in the Danube, which is here a mile wide. It is a military station, contains several churches, a high school, and a quarantine establishment. Silk spinning, brandy distilling, and an active trade in cattle, pigs, and corn, are carried on. Pop. (1880) 17,127.

PANDA (*Ailuurs fulgens*), a quadruped of the family *Ursida* (see BEAR), a native of the Himalaya, the only known species of its genus, which has a very short muzzle, small rounded ears, a moderately long tail, covered with long hair, semi-retractile

claws. The P. is about the size of a large cat. It dwells chiefly in trees, preying much on birds, but it also eats small quadrupeds and large insects. It has a thick, fine, woolly covering, adapting it to a cold climate, concealed by long, soft, glistening, and richly colored hair, mostly chestnut brown, which passes into black on the sides and legs, and into white on the head. The P. is said to excel all other animals in the brilliancy of its fur,

Panda (*Ailuropus fulgens*).

which, however, has not yet acquired any commercial value. The soles of the feet are thickly covered with woolly hair. The P. is also called *Wah* and *Chit-wa*, from a peculiar cry which it utters.

PANDANACEÆ, a natural order of endogenous plants, constituting a remarkable feature in the scenery of many tropical countries, but unknown in the colder regions of the globe. They are trees or bushes, often sending down adventitious roots, sometimes weak and decumbent, or climbing. There are two sections of the order, one (*Pandaneæ*) including the genera *Pandanus*, *Freycinetia*, &c., having long, simple, imbricated leaves, usually spiny on the back and margin, their base embracing the stem, their spiral arrangement often notably visible; the other (*Cyclantheæ*) containing the genera *Cyclanthus*, *Nipa*, (q. v.), *Carludivicia*, *Phytelephas*, &c., having pinnate or fan-shaped leaves, and in general appearance much resembling palms, with which they have been often ranked. The two sections, however, are very similar in their flowers and fruit, in which they not a little resemble the humbler *Araceæ* and *Typhaceæ*. The flowers are mostly unisexual, naked, or with only a few scales, arranged on a spadix, and wholly covering it. The stamens are numerous; the ovaries usually clustered, one-celled, each crowned with a stigma; the fruit consists of fibrous, one-seeded drupes, collected or almost combined, or of berries with many seeds.—There are not quite 100 known species. Some are valuable for the fibre of their leaves, some for their edible fruit, &c. See SCREW PINE, KIEKIE, and NIPA. The unexpanded leaves of *Carludivicia palmata* furnish the material of which *Panama hats* are made. The tree which yields VEGETABLE IVORY (q. v.) is another of the palm-like section of this order.

PAN'D'AVAS, or the descendants of Pân'd'u (q. v.), is the name of the five princes whose contest for regal supremacy with their cousins, the Kurus, the sons of Dhr'itarâsh't'ra, forms the foundation of the narrative of the great epic poem, the *Mahâbhârata* (q. v.). Their names are *Yudhisht'ira*, *Bhîma*, *Arjuna*, *Nakula*, and *Sahadeva*—the former three being the sons of Pân'd'u, by one of his wives, Pr'ithâ; and the latter two, by his other wife Mâdri. But though Pân'd'u is thus the recognized father of these princes, the legend of the *Mahâbhârata* looks upon him, in truth, merely as their father by courtesy; for it relates that Yudhisht'ira was the son of Dharma, the god of justice; Bhîma, of Vâyu, the god of wind; Arjuna, of Indra, the god of the firmament; and Nakula and Sahadeva, of the As'wins, the twin-sons of the sun.

PANDECTS (Gr. *Pandecton*, all receiving; from *pan*, all, and *dechomai*, I receive), one of the celebrated legislative works of the Emperor Justinian (q. v.), called also by the name *Digestum*, or *Digest*. It was an attempt to form a complete system of law from the authoritative commentaries of the jurists upon the laws of Rome. The compilation of the Pandect was undertaken after that great collection of the laws themselves which is known as the *Codex Justinianus*. It was intrusted to the celebrated Tribonianus, who had already distinguished himself in the preparation of the *Codex*. Tribonianus formed a commission consisting of 17 members, who were occupied from the year 529 till 533 in examining, selecting, and compressing, and systematizing the authorities, consisting of upwards of 2000 treatises, whose interpretation of the ancient laws of Rome, was from that time forward to be adopted with the authority of law. A period of ten years had been allowed them for the completion of their work; but so diligently did they prosecute it, that it was completed in less than one-third of the allotted time; and some idea of its extent may be

formed from the fact that it contains upwards of 9000 separate extracts, selected according to subjects from the 2000 treatises referred to above.

The Pandects are divided into 50 Books, and also into 7 Parts, which correspond respectively with Books 1—4, 5—11, 12—19, 20—27, 28—35, 36—44, and 45—50. Of these divisions, however, the latter (into Parts) is seldom attended to in citations. Each Book is subdivided into Titles, under which are arranged the extracts from the various jurists, who are 39 in number, and are by some called the classical jurists, although other writers on Roman law confine that appellation to five of the number, Papinian, Paulus, Ulpian, Gaius (q. v.), and Modestinus. The extracts from these indeed constitute the bulk of the collection; those from Ulpian alone making one-third of the whole work; those from Paulus one-sixth, and those from Papinian one-twelfth. Other writers besides these 39 are cited, but only indirectly, i. e., when cited by the jurists whose works form the basis of the collection. The principle upon which the internal arrangement of the extracts from individual writers was made had long been a subject of controversy. The question seems now to be satisfactorily solved; but the details of the discussion would carry us beyond the prescribed limits. Of the execution of the work, it may be said that although not free from repetition (the same extracts occurring under different heads), and from occasional inaptness of citation, and other inconsistencies, yet it deserves the very highest commendation. In its relations to the history and literature of ancient Rome it is invaluable; and taken along with its necessary complement the *Codex*, it may justly be regarded (having been the basis of all the medieval legislation) as of the utmost value to the study of the principles not alone of Roman, but of all European laws.

PANDORA (i. e., the 'All-endowed'), according to Grecian myth, was the first woman on the earth. When Prometheus had stolen fire from Jupiter, Zeus instigated Hephæstus to make woman out of earth to bring vexation upon man by her graces. The gods endowed her with every gift necessary for this purpose, beauty, boldness, cunning, &c.; and Zeus sent her to Epimetheus, the brother of Prometheus, who forgot his brother's warning against receiving any gift from Zeus. A later form of the myth represents P. as possessing a vessel or box filled with winged blessings, which mankind would have continued to enjoy if curiosity had not prompted her to open it, when all the blessings flew out, except Hope.

PANDOURS, a people of Serbian origin who lived scattered among the mountains of Hungary, near the village of Pandour in the county of Sohl. The name used to be applied to that portion of the light-armed infantry in the Austrian service which is raised in the Slavonian districts on the Turkish frontier. The P. originally fought under the orders of their own proper chief, who was called Harin-Basha, and rendered essential service to the Austrians during the Spanish War of Succession, and afterwards in the Seven Years' War. They originally fought after the fashion of the 'free lances,' and were a terror to the enemy whom they annoyed incessantly. Their appearance was exceedingly picturesque, being somewhat oriental in character, and their arms consisted of a musket, pistols, a Hungarian sabre, and two Turkish poniards. Their habits of brigandage and cruelty rendered them, however, as much a terror to the people they defended as to the enemy. Since 1750 they have been gradually put under a stricter discipline, and are now incorporated with the Austrian frontier regiments. The name is now obsolete.

PAN'D'U, literally, 'white,' is the name of the father of the Pân'd'avas (q. v.), and the brother of Dhr'itarâsh't'ra. Although the elder of the two princes, he was rendered by his 'pallor'—implying, perhaps, a kind of disease—incapable of succession, and therefore obliged to relinquish his claim to his brother. He retired to the Himalaya Mountains, where his sons were born, and where he died. His renunciation of the throne became thus the cause of contest between the Pân'd'avas, his sons, and the Kurus, or the sons of Dhr'itarâsh't'ra.

PANEL (through Fr. from Lat. *pannus*, a piece of cloth, a

Panels.

patch), a space or compartment of a wall, ceiling, woodwork, &c.

enclosed by beams, mouldings, framing, and so forth. It is generally sunk under the plane of the surrounding styles. In wood-work, panels are thinner parts used to fill in strong framing, as in doors, shutters, &c. These are sometimes highly ornamented with tracery, shields, &c. (as in figs. 2 and 3). In late Gothic architecture, the panel is very often carved into the 'linen pattern' (fig. 1). Panelling is a style of ornament greatly used in Elizabethan architecture. The ceilings and walls are covered with it, and every piece of furniture is cut up into panels of every variety of form. Panels are said to 'fielded' when the center of the panel is raised with mouldings, &c.

PANEL (properly the slip or 'pane' of parchment on which the names of the jurors are written) is, in the practice of the English law, used to denote the body or set of jurors, consisting of 12 men, who try a cause, civil or criminal. In Scotch criminal law, the prisoner is usually called the panel.

PANGÉ LINGUA (Lat. 'Proclaim, O Tongue'), one of the most remarkable of the hymns of the Roman Breviary, and like its kindred hymn, *Lauda Sion*, a most characteristic example as well of the medieval Latin versification as of that union of theology with asceticism, which a large class of these hymns present. The Pangé Lingua is a hymn in honor of the Eucharist, and belongs to the service of the Festival of Corpus Christi. It is from the pen of the great angelic doctor, Thomas Aquinas (q. v.) and consists of six strophes of verses in alternate rhyme. Besides its place in the office of the Breviary, this hymn forms part of the service called Benediction with the Blessed Sacrament, and is sung on all occasions of the exposition, procession, and other public acts of Eucharistic worship.

PA'NGOLIN, or PENGOLIN, a name sometimes extended to all the species of *Manis* (q. v.), but originally belonging to *M. pentadactyla*, also called SHORT-TAILED MANIS, and in some parts of India BAJJERKEIT; this species being a native of most parts of the East Indies, and P., its Malay name, derived from a word which signifies to roll up; the animal having the habit of

Pangolin (*Manis pentadactyla*).

rolling itself up, on apprehension of danger, into a compact ball, the head in the center, and its muscular mail-covered tail enfolded all. The food of the P. consists chiefly of ants, and like the rest of the genus, it is entirely destitute of teeth, and has a round, extensible tongue. Its claws are long and strong; it doubles them up like the American ant-eaters when it walks. It resides in burrows, which it excavates to the depth of seven or eight feet in the ground. It is capable of climbing trees, and the tail is prehensile. The whole length of the animal including the tail, is almost five feet, the tail being not quite half the length of the body. It is a gentle animal, easily tamed, and of an affectionate disposition.

PANIC is where fear, whether arising from an adequate or inadequate cause, obtains the mastery over every other consideration and motive, and urges to dastard extravagance, or hurries into danger, or death. An inexplicable sound causes a rush from a church, a vague report in the market-place causes a run on a bank, and precipitate the very events that are dreaded. This emotion either differs from natural apprehension, or presents so intense and uncontrollable a form of the feeling, that it is propagable from one person to another, and involves alike the educated and ignorant—those who act from judgment as well as those who act from impulse. There are, besides this feature, several grounds for believing that such manifestations of involuntary terror are of morbid origin, and should be regarded as moral epidemics. They have generally arisen during, or have followed, seasons of scarcity and physical want and disease, the ravages of war, or periods of great religious fervour and superstition. The dancing mania, the retreat of the French army from Moscow, and recent and familiar commercial panics afford illustrations of certain of these relations. The most notable instance of universal panic, and that which demonstrates most aptly the connection here indicated, is the dread of the approaching end of the world which pervaded all minds, and almost broke up human society in the 10th century. The empire of Charlemagne had fallen to pieces; public misfortune and civil discord merged into misery and famine so extreme that cannibalism prevailed even in Paris; superstitious and vague predictions became formalized into a prophecy of the end of all

things and universal doom in the year 1000. This expectation, suspended even vengeance and war. The 'truce of God' was proclaimed. Enormous riches were placed upon the altars. Worship and praise never ceased. The fields were left uncultivated; serfs were set free; four kings and thousands of nobles retired to the cloister; and all men, according to their tendencies, prepared to die.

It is worthy of note that during all pestilences there have arisen epidemic terrors, not so much of the devastations of disease, as of plots and poisonings directed by the rich against the poor. Even where these epidemic terrors are legitimately traceable to local and physical causes, as in the case of the singular affection timor, which occurs in the marshy and unhealthy districts in Sardinia, the tremor and trepidation, and other phenomena, are ascribed to the magical influence of enemies. For the origin of the name, see PAN.

PA'NICLE, in Botany, a mode of Inflorescence (q. v.) in which the floral axis is not only divided, but also subdivided more or less frequently. The panicle may thus be regarded as a Raceme (q. v.), of which the branches (or flower-stalks) are branched. The panicle is a very common kind of inflorescence. Most of the grasses exhibit it, and many other plants, both endogenous and exogenous. The common lilac affords a good example of it. The panicle, variously modified as to its form, and the arrangement and relative lengths of its branches and branchlets, becomes a Cyme (q. v.), Thyrsus (q. v.), &c.

PA'NICUM. See MILLET.

PAN'INI, the greatest known grammarian of ancient India, whose work on the Sanscrit language has up to the present day remained the standard of Sanscrit grammar. Its merits are so great that P. was ranked among the R'ishis (q. v.), or inspired seers, and at a later period of Sanscrit literature, was supposed to have received the fundamental rules of his work from the god S'iva himself. Of the personal history of P., nothing positive is known, except that he was a native of the village S'alatura, situated north-west of Attock, on the Indus—whence he is also sur-named S'alaturiya—and that his mother was called Dakshi, wherefore, on his mother's side, he must have been a descendant of the celebrated family of Daksha. A tale-book, the *Kathasaritsagara* (i. e., the ocean for the rivers of tales), gives, indeed, some circumstantial account of the life and death of P.; but its narrative is so absurd, and the work itself of so moderate a date—it was written in Cashmere, at the beginning of the 12th c.—that no credit whatever can be attached to the facts related by it, or to the inferences which modern scholars have drawn from them.

According to the views expressed by Goldstücker (*Pānini, his Place in Sanscrit Literature*: London, 1861), it is probable that P. lived before S'akyamuni, the founder of the Buddhist religion, whose death took place about 543 B. c., but that a more definite date of the great grammarian has but little chance of ascertainment in the actual condition of Sanscrit philology.—The grammar of P. consists of eight Adhyāyas, or books, each book comprising four Pādas, or chapters, and each chapter a number of Sūtras (q. v.) or aphoristical rules. The latter amount in the whole to 3996; but three, perhaps four, of them did not originally belong to the work of Pānini. The arrangement of these rules differs completely from what a European would expect in a grammatical work, for it is based on the principal of tracing linguistic phenomena, and not concerned in the classification of the linguistic material, according to the so-called parts of speech. A chapter, for instance, treating of a prolongation of vowels, will deal with such a fact wherever it occurs, be it in the formation of bases, or in conjugation, declension, composition, &c. The rules of conjugation, declension, &c., are, for the same reason, not to be met with in the same chapter or in the same order which European grammars would teach them; nor would any single book or chapter, however apparently more systematically arranged—from a European point of view—such as the chapters on affixes or composition, suffice by itself to convey the full linguistic material concerned in it, apart from the rest of the work. In a general manner, P.'s work may therefore be called a natural history of the Sanscrit language, in the sense that it has the strict tendency of giving an accurate description of facts, instead of making such a description subservient to the theories according to which the linguistic material is usually distributed by European grammarians.

Whatever objections may be raised against such an arrangement, the very fact of its differing from that in our grammars makes it peculiarly instructive to the European student, as it accustoms his mind to survey language from another point of view than that usually presented to him, and as it must induce him, too, to question the soundness of many linguistic theories now looked upon as axiomatic truths. As the method of P. requires in a student the power of combining many rules scattered all over the work, and of combining, also, many inferences to be drawn from these rules, it exercises, moreover, on the mind of the stu-

dent an effect analogous to that which is supposed to be the peculiar advantage of the study of mathematics. The rules of P. were criticised and completed by Kātyāyana (q. v.), who, according to all probability was the teacher, and therefore the contemporary, of Patanjali; and he in turn, was criticised by Patanjali (q. v.), who sides frequently with Pāṇini. These three authors are the canonical triad of the grammarians of India; and their works are in truth, so remarkable in their own department, that they exceed in literary merit nearly all, if not all, grammatical productions of other nations, so far as the two classes are comparable. The rules of P. were commented on by many authors. The best existing commentary on them is that called the *Kās'ikāvar'itta*, by Vāmana Jayāditya, which follows these rules in their original order. At a later period, attempts were made to arrange the rules of P. in a manner which approaches more to the European method; the chief work of this category is the *Siddhānta-Kaumudī*, by Bhaṭṭa'oji-dīkshita. P. mentions, in his Sūtras, several grammarians who preceded him, amongst others, Ś'akātāyana.

Manuscripts of a grammar ascribed to a grammarian of this name exist in the Library of the India Office in London, and in the Library of the Board of Examiners at Madras. On the ground of a few pages only of the latter an attempt has been very recently made to prove that this grammar is the one referred to by P., and therefore older than the work of the latter. But the facts adduced in proof of this hypothesis are so ludicrously weak, and the reasoning upon them so feeble and inconclusive, whereas, the evidence in favor of the comparatively recent date of this work is so strong, that no value whatever can be attached to this hasty hypothesis. For the present, therefore, P.'s work still remains the oldest existing grammatical work of India, and probably of the human race. The Sūtras of P., with a modern commentary by two native pandits, and with extracts from the *Vārttikas* of Kātyāyana and the *Mahābhāṣya* of Patanjali, were edited at Calcutta in 1809. This edition, together with the modern commentary, but with garbled extracts from the extracts mentioned, was reprinted at Bonn in 1839—1840 by Dr. O. Boehtlingk, who added to it remarks of his own and some indices.—For the literature connected with P., see Colebrooke's preface to his *Grammar of the Sanscrit Language* (Calc. 1805), and Goldstücker's *Pāṇini*, &c., as mentioned above.

PANIPUT, the chief town of the district Kurnal, in the division of Delhi, Punjab, is situated 54 miles (by road 78 miles) north by west from Delhi, in a fertile tract, the resources of which are largely developed by artificial irrigation. Pop. (1869) 25,276. Being a station on the great military road between Afghanistan and the Punjab, and to some extent an outpost of Delhi, it has been at various times the scene of strife between the inhabitants of India and invaders. The first great battle of P. was fought in 1526, and gained by Mirza Baber, the ex-ruler of Ferghana, at the head of 12,000 Mongols, over Ibrahim the emperor of Delhi, whose unwelcome array numbered 100,000 men, with 1000 elephants. This victory seated Baber on the throne of Hindustan as the first of the 'Great Mogul' dynasty. The second great battle was fought, in 1556, by the Mongols under Akbar, grandson of Baber, and third of the Mogul emperors, against Hemu, an Indian prince who had usurped the throne of Delhi. Hemu's army was defeated with great slaughter, and himself slain. The third battle was fought on the 14th of January 1761, between Ahmed Abdali, ruler of Afghanistan, and the then invincible Marhattas. The Jats, who had been forced to join the Marhattas, deserted to the Afghans at a time when victory seemed to be declaring for the former; and this act of treachery, together with the loss of their leaders, threw the Marhattas into confusion, and in spite of their most resolute valor they suffered a total defeat. They left 50,000 slain on the field of battle, including all their leaders except Holkar, and 30,000 men were killed in the pursuit, which was continued for four days. The Marhattas never recovered this crushing blow. It was at Kurnaul, a town a little to the north of P., that Nadir Shah of Persia, in 1739, won the celebrated battle over the Mogul emperor, which placed North-Western India at his feet.

PANIZZI, SIR ANTONIO, principal librarian of the British Museum from 1856 to 1866, was born on the 16th Sept. 1797, at Brescello, in the *ci-devant* duchy of Modena. For his education he was sent first to the public school of Reggio, and afterwards to the university of Padua, where, in 1818, he took the degree of Doctor of Laws, with a view to practising at the bar. Early in life his sympathies were enlisted on behalf of the friends of Italy, as opposed to domestic tyranny and foreign intrusion, and when, in 1821, the popular revolution broke out in Piedmont, the young advocate became one of its leaders. The attempt, however, failed; and P., who had been denounced by a pretended friend, was arrested at Cremona. Having by some means contrived to escape, he took refuge in Lugano, and from thence in a short time found his way to Geneva. Meanwhile, during his absence, he was tried at home *per contumaciam*, as it is called, and sentenced to death,

with confiscation of property. Nor was he allowed to remain at Geneva. The governments of Austria and Sardinia demanded from the Swiss Confederation the expulsion of all concerned in the recent outbreak, and among these P. was obliged to depart. Forbidden to pass through France, he reached England by way of Germany and the Netherlands. He now resided for about a month in London, when he proceeded to Liverpool, with an introduction from Ugo Foscolo to Roscoe the historian, who received him with the utmost hospitality. At Liverpool, where he was introduced into the best circles by Mr. Roscoe, he taught Italian, and continued to reside in that town until 1828, when he came to London again, and was chosen professor of Italian in the university of London, just then opened for students. In 1831, through the instrumentality of Lord Brougham, he was appointed one of the assistant-librarians in the British Museum; and upon the retirement of the Rev. Mr. Baber, in 1837, from the office of Keeper of the Printed Books, P. was appointed his successor. In the previous year there had been a parliamentary committee on the state of the British Museum, before which P. gave valuable evidence, and likewise urged the adoption of measures for the improvement and augmentation of the library, which, upon becoming keeper, he was in a still better position to advocate.

In 1838 he superintended the removal of the printed books from the old suite of rooms in Montague House to the new library; and in the same year, in conjunction with some of his assistants, he drew up the well-known 91 rules for the formation of a new catalogue of the library. These rules were approved by the trustees, and the first volume of a catalogue framed after them was printed and published in 1841. No other volume has been since published, and P., before a royal commission of inquiry into the Museum in 1847, justified the suspension of the printing until the whole catalogue should be finished. In 1845, P. drew up an elaborate report of the deficiencies existing in the library, in consequence of which the trustees applied to the Lords of the Treasury for 'an annual grant of £10,000 for some years to come, for the purchase of books of all descriptions.' This grant having been obtained, the library rapidly increased in numbers, to such a degree that in 1849 the books amounted to 435,000, as compared with 235,000, the ascertained number in 1838. The number of volumes is now estimated at considerably over 1,000,000. Upon the resignation of Sir H. Ellis, in 1856, P. was appointed to the post of principal librarian of the British Museum, an office he held ten years. In a literary capacity, P. is known by an edition of the *Orlando Innamorato di Boiardo*, and *Orlando Furioso di Ariosto: with an Essay on the Romantic Narrative Poetry of the Italians, Memoirs and Notes by A. Panizzi* (9 vols. Lond. 1830—1834). He also edited the *Sonetti e Canzone* of Boiardo (Lond. 1835), and a collection of reprints of the first four editions of the *Divina Commedia* (Lond. 1858). He was also the author of a privately-printed pamphlet, *Chi era Francesco da Bologna*, proving the identity of the type-founder employed by Aldus, and the inventor of the well-known Aldine or Italic type, with the painter Francesco Francia. P. wrote occasional articles for the reviews. P., who retired on a pension in 1866, and in 1869 received the order of K.C.B., died 8th April 1879. His *Epistolarium* was announced in 1880, also a *Life* by Fagan.

PA'NJIM. See GOA.

PA'NNAH, or PU'NNAH, a decayed town of India, in the district of Bundelcund, stands on the north-eastern slope of a plateau, 115 miles south-west of Allahabad. It was formerly a large, thriving, and well-built town; but whole streets are now desolate, or are tenanted only by monkeys, which, posted on the roof or at the windows, view the town's-people without alarm. The palace of the rajah is a beautiful building, surmounted by elegant kiosks, but is in many places ruinous. The source of the former prosperity of P. was its rich diamond mines. Owing to the diminished value of the gem, however, and the increased tax upon the produce of the mines, this branch of industry has much fallen off. The diamonds are generally tinted with color; very few of them being of first-water, or completely colorless. This town is the chief place of a territory of the same name, which is bounded on the north by the British district of Banda, and on the south by the British district of Nerbudda. See BUNDELCUND.

PANNELS, in Artillery, are the carriages upon which mortars and their beds are conveyed on a march.

PANNO'NIA, a province of the ancient Roman empire, bounded on the N. and E. by the Danube, on the W. by the mountains of Noricum, and on the S. reaching a little way across the Save; and thus including part of modern Hungary, Slavonia, parts of Bosnia, of Croatia, and of Carniola, Styria, and Lower Austria. It received its name from the Pannonians, a race of doubtful origin, but who at first dwelt in the country between the Dalmatian Mountains and the Save, in modern Bosnia, and afterwards more to the south-east in Moesia. The Roman arms were first turned against them and their neighbors, the Iapydes, by Augustus in 35 B.C., and after the conquest of Segestica or

Siscia (Siszek) he subdued them. An insurrection took place in 12 B.C., which Tiberius crushed after a long struggle; and a more formidable one of the Dalmatians and Pannonians together in 6 A.D., which was suppressed by Tiberius and Germanicus, but not till 8 A.D.

Fifteen legions had to be assembled against the Pannonians, who mustered 200,000 warriors. Hereupon the Pannonians settled in the more northern countries, which received their name, and of which the former inhabitants, the Celtic Boii, had been in great part destroyed in Caesar's time. The country was now formed into a Roman province, which was secured against the inroads of the Marcomanni and Quadi by the Danube, and on its other frontiers had a line of fortresses. Military roads were constructed by the conquerors, who also planted in the country many colonies and municipia, and thus gave it a rough coating of civilization. Great numbers of the Pannonian youth were drafted into the Roman legions, and proved, when disciplined, among the bravest and most effective soldiers in the imperial army. P. was subsequently divided into Upper (or Western) and Lower (or Eastern) P., and under Galerius and Constantine underwent other changes. Upper Pannonia was the scene of the Marcomannic war in the 2d century. In the 5th c. it was transferred from the Western to the Eastern Empire, and afterwards given up to the Huns. After Attila's death, in 453, the Ostrogoths obtained possession of it. The Longobards under Alboin made themselves masters of it in 527, and relinquished it to the Avari upon commencing their expedition to Italy. Slavonian tribes also settled in the south. Charlemagne brought it under his sceptre. In the reigns of his successors, the Slavonians spread northward, and the country became a part of the great Moravian kingdom, till the Magyars or Hungarians took it in the end of the 9th century. In the time of the Romans, Siscia (Siszek), Vindobona (Vienna), Carnuntum (near Hainburg), and Arrabo (Raab) were among its principal towns.

PANORAMA (Gr. *pan*, all, *orama*, a view), a pictorial representation of the whole surrounding landscape as seen from one point. The invention of the panorama is claimed by the Germans for Professor Breisig of Danzig, but it does not appear that he ever constructed one. The real inventor was Mr. Barker, an ingenious artist of Edinburgh, to whom the idea occurred while taking a sketch of the city from the top of Arthur Seat. After surmounting numerous difficulties—one of which was the invention of a new kind of perspective for the horizontal lines—he succeeded in producing an effective panoramic view of Edinburgh, which was exhibited in that city in 1788, and in London in the following year. The next panorama executed by Barker was a view of London from the top of the Albion Mills. A large building was now erected in Leicester Square for the exhibition of such views. On Mr. Barker's death in 1806, he was succeeded by his son, in partnership with a pupil, Mr. Burford, the painter of the chief modern panoramas. The first step in the construction of a panorama is to obtain sketches of the entire region to be represented; each sketch is a representation of a portion of the landscape in the form of a sector of a circle, with the sketcher's position as a center, and the horizon for circumference. The canvas to which the sketches are to be transferred is hung round the sides of a circular room, and forms the surface of a cylinder, on the inside of which the panorama is painted. The canvas, brushes, &c., are of the finest description manufactured, and the painting and coloring are elaborated in the most careful manner, in order to render the optical illusion—which every one who has seen a good panorama must have experienced—as complete as possible.

The stage from which the picture is viewed is placed in the center of the room, about 30 feet on every side from the picture; the picture itself is fastened above to a strong circular hoop, and, hanging down, has its lower edge fastened to a similar hoop, which is heavily weighted to keep the picture steady. The light is admitted by an aperture in the roof, which is concealed by an awning from the spectators on the stage. Notwithstanding important defects in the panorama, one of which is that the light more strongly illumines the upper than the lower parts of the picture—thus throwing the foreground comparatively into shade—many cases are on record of spectators being for the time completely under the influence of mental illusion. One of the best instances of this occurred during the exhibition of the third panorama in London. Part of the view consisted of a representation of the wreck of a ship's boat, with sailors struggling in the waves; and at sight of this, a dog belonging to one of the spectators at once leaped over the handrail to the rescue of the supposed drowning men. Panoramas, though frequently exhibited in France, Germany, and other European countries, have met with little success out of Great Britain. The most popular panorama ever executed was that of the Battle of Waterloo, the exhibition of which brought in ten thousand pounds. There are many modifications of the panorama, but that above described is the most important.

PANSLAVISM. This term is applied to the movement lately set on foot, and generally ascribed to Russian influence, for the

amalgamation of all races of Slavonic descent into one body, having one language, one literature, and one social polity. The writings of Adam Gurowski and Kollar, and the anonymous pamphlet which appeared at Leipzig in 1837, under the title of *Die Europäische Pentarchie*, have exercised a very widespread influence in this direction among all the Slavonic people of the German states; and although the other nations of Europe have hitherto had no reason to anticipate any practical results from a movement towards Pan Slavism, the Slavonians of the Austrian empire have always taken occasion to show that they regarded themselves as standing apart from German interests in times of public disturbance. Thus, in 1848, instead of taking part with their fellow-citizens in the election of representatives to the German parliament at Frankfurt, the leading promoters of Pan Slavism summoned a Slavonic congress at Prague, which was attended by Slavonians from Bohemia, Moravia, and Silesia, and by Slavonic Poles, Croats, Servians, and Dalmatians, who appeared in their national costumes. The impracticability of the grand schemes promulgated in the manifestoes of the conclave, had been sufficiently shown ere the congress was interrupted by a democratic rebellion, which was suppressed with much bloodshed. Since 1860, when questions of nationality began to come more into the foreground, P. has exercised some direct influence on Austrian affairs: both northern and southern Slavs tending towards united action in opposition to the centralistic and dualistic aims of Germans and Magyars respectively. In 1867 a great Slavonic congress was held at Moscow without result. Pan Slavistic tendencies contributed to the great changes that took place in 1877-78 in the Balkan peninsula.

PANSY. See VIOLET.

PA'NTAGRAPH (Gr. *panta*, all, *graphein*, to delineate), an instrument by the aid of which any engraving may be copied on paper, though its use is in practice restricted to the copying of maps and plans. The copy can be drawn to any scale. The instrument consists of four rods, AB, AC, DE, and EF, jointed together, as in the figure; the points D and E are so taken that AD is equal to EF, and AE to DF, and consequently ADEF is always a parallelogram. If C be a determinate point near the end of the rod AE, and any line, CHB, be drawn cutting the other three rods, the triangles BAC and BDH are similar; so that when the point B is fixed, the points C and H, which can from

the structure of the instrument, move in any direction, will describe similar figures different in size; that described by C being to that described by H in the proportion of CB to HC. The practical working of the instrument is as follows: The points H and B are determined by the ratio BH to BC, which is the proportion the scale of the copy bears to that of the original; a socket, which slides along the arm, is fastened exactly at B on the under side; below this is placed a heavy weight, with a stalk fitting into the socket, thus rendering B the center of motion of the instrument, if the weight be heavy enough. A pencil is fitted into another socket at H, and a rod of metal with a sharp point, called the *tracer*, is fastened at C, and the instrument is fitted with castors at various points underneath, to allow of its being moved freely. The operator then passes the tracer over the outline to be copied, and simultaneously the pencil at H makes the copy on the required scale. If a copy on a scale nearly as large as the original be required, the fulcrum must be placed in DF, and the pencil in DB; while if a magnified copy be required, the pencil and tracer must exchange the positions assigned them in the first case. The defects of this instrument are its weight and the difficulty of rendering it perfectly mobile, both of which prevent that steady motion of the tracer which is necessary for making an accurate copy.

To remedy these defects, the pantagraph has been constructed

in a variety of forms, all of which, however, like the one described, depend upon the principle that the two triangles which have for their angular points, the fulcrum the pencil-point and a joint, and the fulcrum the tracer-point and a joint, must always preserve their similarity.

PANTELLA'RIA, a volcanic island in the Mediterranean, 36 miles in circumference, and lying 60 miles S. W. of the Sicilian coast. The chief products are wine, oil, cotton and fruit.

PANTHAYS, a Mohammedan community occupying the province of Yun-nan in the south-west of China, who asserted their independence in 1855. In 1859 they captured Talifoo, the second city of the province, and in 1858, the capital. Their leader Wensoi (King Suleiman) established his authority over about 4,000,000 of people, of whom not above a tenth were Mohammedans. In 1866 the Chinese government recognized the independence of the P., and in 1872 their king sent his son Hassan on a mission to Europe. Meanwhile the Chinese again attacked the P., defeated them utterly, and finally suppressed their empire. P. is an anglicised form of *Pan-si*, the name by which the Mohammedans called themselves.

PA'NTHEISM (Gr. *pan*, all, and *theos*, God), the name given to that system of speculation which, in its spiritual form, identifies the universe with God (*akosmism*), and in its more material form, God with the universe. It is only the latter kind of pantheism that is logically open to the accusation of Atheism (q. v.); the former has often been the expression of a profound religiosity. The antiquity of pantheism is undoubtedly great, for it is prevalent in the oldest known civilization in the world—the Hindu. Yet it is a later development of thought than Polytheism (q. v.), the natural instinctive creed of primitive races, and most probably originated in the attempt to divest the popular system of its grosser features, and to give it a form that would satisfy the requirements of philosophical speculation. Hindu pantheism as *akosmism* is taught especially by the Upanishads (q. v.), the Vedānta (q. v.), and Yoga (q. v.) philosophies, and by those poetical works which embody the doctrines of these systems; for instance, the Bhagavadgītā, which follows the Yoga doctrine. It is poetical and religious, rather than scientific, at least in its phraseology; but it is substantially similar to the more logical forms developed in Europe. The Hindu thinker regards man as born into a world of illusions and entanglements, from which his great aim should be to deliver himself. Neither sense, nor reason, however, is capable of helping him; only through long continued, rigorous, and holy contemplation of the supreme unity (Brahma) can he become emancipated from the deceptive influence of phenomena, and fit to apprehend that he and they are alike but evanescent modes of existence assumed by that infinite, eternal, and unchangeable Spirit who is all in all. Hindu pantheism is thus purely spiritual in its character; matter and (finite) mind are both alike absorbed in the fathomless abyss of illimitable and absolute being.

Greek pantheism, though it doubtless originated in the same way as that of India, is at once more varied in its form, and more ratiocinative in its method of exposition. The philosophy of Anaximander (q. v.) the Milesian may almost, with equal accuracy, be described as a system of atheistic physics or of materialistic pantheism. Its leading idea is, that from the infinite or indeterminate (*to apeiron*), which is 'one yet all,' proceed the entire phenomena of the universe, and to it they return. Xenophanes (q. v.), however, the founder of the Eleatic school, and author of the famous metaphysical *mot*, *Ex nihilo, nihil fit*, is the first classical thinker who promulgated the higher or idealistic form of pantheism. Denying the possibility of creation, he argued that there exists only an eternal, infinite One or All, of which individual objects and existences are merely illusory modes of representation; but as Aristotle finely expresses it—and it is this last conception which gives to the pantheism of Xenophanes its distinctive character 'casting his eyes wistfully upon the whole heaven, he pronounced that unity to be *God*.' Heraclitus (q. v.), who flourished a century later, reverted to the material pantheism of the Ionic school, and appears to have held that the 'All' first arrives at consciousness in man, whereas Xenophanes attributed to the same universal entity, intelligence, and self-existence, denying it only personality. But it is often extremely difficult, if not impossible, to draw or to see the distinction between the pantheism of the earlier Greek philosophers and sheer atheism. In general, however, we may affirm that the pantheism of the Eleatic school was penetrated by a religious sentiment, and tended to absorb the world in God, while that of the Ionic school was thoroughly materialistic, tended to absorb God in the world, and differed from atheism rather in name than in fact. But the most decided and the most spiritual representatives of this philosophy among the Greeks were the so-called 'Alexandrian' *Neo-platonists*

(q. v.), in whom we see clearly, for the first time, the influence of the East upon Greek thought.

The doctrines of Emanation, of Ecstasy, expounded by Plotinus (q. v.) and Proclus (q. v.), no less than the fantastic Dæmonism of Iamblichus (q. v.), point to Persia and India as their birthplace, and in fact differ from the mystic teaching of the Vedānta only by being presented in a more logical and intelligible form, and divested of the peculiar mythological allusions in which the philosophy of the latter is sometimes dressed up.

During the middle ages, speculation was, for the most part, held in with tight reins by the church, and in consequence we hear little of pantheism. Almost the only philosopher who advocated, or who even seems to have thought about it, is John Scotus Erigena (see ERIGENA), who was probably led to it by his study of the Alexandrians, but his speculations do not appear to have been thought by him incompatible with a Christian faith; and in point of fact there are several profoundly mystical expressions employed in the new Testament, especially in the Epistles of John, in which the soaring spiritualism of Christianity culminates in language that has at least a pantheistic form; e. g., 'God is love; and he that dwelleth in love dwelleth in God, and God in him.' Erigena is regarded as the link that unites ancient and modern pantheism. We find in him now a reflection of the East and of Greece, and now a foreshadowing of the doctrines of Schelling and Hegel. His opinions were, with some scholastic modifications, introduced, in the 12th and 13th centuries, into theology by Amalric or Amaury de Chartres (a disciple also of Abelard), and his pupil David de Dinant, who were condemned as heretics by a council held at Paris.

Modern pantheism first shows itself in Giordano Bruno (q. v.), burned at Rome for his opinions in 1600. In Bruno reappear the speculations of the Eleatics and the Neo-Platonists, but with a still more definite recognition than we meet with in them of an absolutely perfect supreme spirit. The universe, in the eyes of the unfortunate Italian, is not, properly speaking, a creation, but only an emanation of the Infinite mind—the eternal expression of its infinite activity; and hence the Infinite mind penetrates and fills, with different degrees of consciousness, all the heights and depths of the universe. To see God everywhere, to realize that He alone is, and that all else is but a perishable phenomenon or passing illusion—that there is but *one* intelligence in God, man, beast, and what we call matter—this should be the aim of all true philosophy. Spinoza (q. v.) comes next among pantheists in the order of time, but he is perhaps the greatest, certainly the most rigorous and precise of the whole class that either the ancient or the modern world has seen. His system is based, like the geometry of Euclid, on certain definitions and axioms, and he claims to have given it as conclusive and mathematical a demonstration as the latter. None will deny the keenness and cogency of his ratiocination. But human beings will not be forced into pantheistic convictions by any mere logical goad, however sharp; and the system, impenetrable as it seems, has never had a formal adherent. The principal result at which, after a long, firm-linked chain of reasoning, Spinoza arrives, is, that there is but one substance, infinite, self-existent, eternal, necessary, simple, and indivisible, of which all else are but the modes. This substance is the self-existent God.

To call Spinoza an atheist is ridiculous. The extravagant phrase of Schleiermacher, 'a God-intoxicated man' (*'ein gott-trunkener mann'*), would be greatly nearer the truth, for no human system of philosophy whatever exhibits such an all-controlling and even overwhelming sense of the omnipresent God. Many critics have said that he was far more of an old Hebrew in his system than he dreamed. Although he had no direct followers, he exercised great influence on the development of metaphysical speculation in Germany, where, with the exception of Kant (q. v.), the three greatest philosophers of recent times—Fichte (q. v.), Schelling (q. v.), and Hegel (q. v.)—have all promulgated systems of a thoroughly pantheistic and ideal character. Neither England, France, nor America has produced a single great pantheistic philosopher (unless Mr. Emerson be regarded as such); but there is an immense amount of pantheistic sentiment floating about in the poetry, criticism, theology, and even in the speculative thinking, in these and all European countries in the present age. This is attributable to the ravages made by biblical criticism, and the progress of the physical sciences in the region of religious beliefs. Multitudes of men are puzzled what to think and what to believe. They do not like to face the fact that they have actually lost faith in revelation, and are no longer relying for help and guidance on the Spirit of God, but on the laws of nature; so they take refuge from the abhorred aspect of the naked truth that they are 'atheists' in a cloud of rose-colored poetical phrases, which, if they mean anything, mean pantheism.

PANTHE'ON, a Greek or Roman temple dedicated to all the gods. The 'Pantheon' of Rome, now the church of Santa Maria Rotonda, is the only ancient edifice in Rome that has been per-

fectly preserved. The P. is lighted through one aperture in the center of its magnificent dome. It was erected by Agrippa, son-in-law of Augustus, 27 B.C.

Half Section of Pantheon (from Fergusson).

PANTHER (*Felis pardus*), one of the largest *Felidae*, now supposed to be identical with the Leopard (q. v.), or a mere variety of it, differing only in its larger size and deeper color. Cuvier

American Panther or Puma (*Felis concolor*).

distinguishes the P. from the leopard, but without stating any characters other than those of color. The name P. (vulg. 'Painter') is given to the Puma (q. v.) in America.

PANTHER, in Heraldry, is borne gardant, and incensed, i. e., with fire issuing from his mouth and ears.

PA'NTOMIME, among the ancient Romans, denoted not a spectacle but a person. The pantomimes were a class of actors who (as the name implies) acted not by speaking, but wholly by mimicry—gesture, movements, and posturings—corresponding therefore pretty closely to the modern ballet-dancers. When they first made their appearance in Rome cannot be ascertained; probably the *histriones* (Etrusc. *hister*, a dancer) brought from Etruria to Rome 364 B. C. were pantomimes; but the name does not once occur during the republic, though it is common enough from the very dawn of the empire. Augustus showed great favor to this class of performers, and is consequently supposed by some writers to have been himself the inventor of the art of dumb acting. The most celebrated pantomimes of the Augustan age were Bathyllus (a freedman of Mæcenas), Pylades, and Hylas. The class soon spread over all Italy and the provinces, and became so popular with the Roman nobles and knights (who used to invite male and female performers to their houses to entertain their guests), that Tiberius reckoned it necessary to administer a check to their vanity, by issuing a decree forbidding the aristocracy to frequent their houses, or to be seen walking with them in the streets. Under Caligula they were again received into the imperial favor; and Nero, who carried every unworthy weakness and vice to the extremity of caricature, himself acted as a pantomime. From this period they enjoyed uninterrupted popularity as long as paganism held sway in the empire.

As the pantomimes wore masks, no facial mimicry was possible; everything depended on the movements of the body. It was the

hands and fingers chiefly that spoke; hence the expressions, *manus, loquacissima, digiti clamosi*, &c. To such perfection was this art carried, that it is said the pantomimes could give a finer and more precise expression to passion and action than the poets themselves. The subjects thus represented in dumb show were always mythological, and consequently pretty well known to the spectators. The dress of the actors was made to reveal, and not to conceal the beauties of their person; and as, after the 2d c., women began to appear in public as pantomimes, the effect, as may easily be supposed, of the æsthetical costume was injurious to morality. Sometimes these pantomimic actresses even appeared quite naked before an audience—a thing which could never have happened had the Roman communities not become thoroughly base, sensual, and impure. It was quite natural, therefore, that pantomimic exhibitions should have been denounced by the early Christian writers, as they even were by pagan moralists like Juvenal.

Under **HARLEQUIN** is described the character of the modern pantomimes, which word denotes not the performers, but the pieces performed. A few additional facts are here given to complete that notice. The Christmas Pantomime, or Harlequinade, is, in its present shape, essentially a British entertainment, and was first introduced into this country by a dancing-master of Shrewsbury named Weaver, in 1702. One of his pantomimes entitled *The Loves of Mars and Venus*, met with great success. The arrival, in the year 1717, in London of a troupe of French pantomimists with performing dogs gave an impetus to this kind of drama, which was further developed in 1758 by the arrival of the Grimaldi family, the head of which was a posture-master and dentist.

Under the auspices of this family, the art of producing pantomimes was greatly cultivated, and the entertainment much relished. Joseph Grimaldi, the son of the dentist, was clever at inventing tricks and devising machinery, and *Mother Goose*, and others of his harlequinades, had an extended run. At that time the wit of the clown was the great feature; but by and by, as good clowns became scarce, other adjuncts were supplied, such as panoramas or dioramic views; and now the chief reliance of the manager is on scenic effects, large sums of money being lavished on the *mise en scene*. This is particularly the case as regards the transformation scene—i. e., the scene where the characters are changed into clown, harlequin, &c.—as much as £1000 being frequently spent on this one effort. In London alone, a sum of about £40,000 is annually expended at Christmas time on pantomimes. The *King of the Peacocks*, a pantomime produced at the London Lyceum Theatre during the management of Madame Vestris, cost upwards of £3000. Even provincial theaters, such as those of Manchester or Edinburgh, consider it right to go to considerable expense in the production of their Christmas pantomime.

PA'OLI, PASCAL, a famous Corsican patriot, was born in 1726, at Morosaglia, in Corsica. His father, having taken a leading part in the unsuccessful insurrection of the islanders against the Genoese and their French allies, was obliged to retire to Naples in 1739, taking his son with him. Here P. received an excellent education. In July 1755, he was summoned by the supreme magistracy to Corsica, and was elected captain-general of the island, and the chief of a democratic government, possessing all the power of a king, but without the title. He energetically and successfully applied himself to the reformation of the barbarous laws and customs of the island, and at the same time to the expulsion of the Genoese, who, notwithstanding the aid they received from an influential section of the islanders, were deprived of nearly all their strongholds, their fleet was defeated, and they were finally obliged to seek help from France.

After the withdrawal of the French troops, they were again speedily deprived of the places they had recaptured, and in 1768 they ceded the island to France. P. refused all the advantageous offers by which the French government sought to bribe him, as he had before refused those of the Genoese, and continued to struggle for the independence of his country, but he was signally defeated by the Comte de Vaux, at the head of the French troops, and the French became masters of the island. After one year's struggle, P. was compelled to take refuge on board of a British frigate, in which he sailed for England, where he was treated with general sympathy. Twenty years afterwards, the French revolution of 1789 recalled him to Corsica, and as a zealous republican he entered into the schemes of the revolutionary party; but during the anarchy of France in 1792—1793, he conceived a scheme for making Corsica an independent republic. Until this time he had been on the best terms with the Bonaparte family, but they now joined the Jacobin party whilst he allied himself with Britain, favored the landing of 2000 British troops in the island in 1794, and joined them in driving out the French. He then surrendered the island to George III., but becoming dissatisfied with the government, he quarrelled with the British viceroy, whilst many

of his countrymen were displeased with the course he had adopted in allying himself with the British. He therefore retired from the island in 1796, and spent the remainder of his life in the neighborhood of London. P. died near London, February 5, 1807.

PA'PA, a large market town in the west of Hungary, stands in a beautiful district on the Tapolcza, an affluent of the Marczal, 60 miles south-south-east of Presburg. It contains a stately castle, with a beautiful garden, handsome Catholic and Lutheran churches, a Catholic gymnasium, Reformed college, and an hospital. Stoneware, cloth, and pipes are manufactured, and a trade in wine is carried on. Pop. (1869) 14,223.

PAPA, the Latin form of the title now, in the Western Church, given exclusively to the Bishop of Rome. Originally, however, meaning simply 'father,' it was given indiscriminately to all bishops. Tertullian (*De Pudicitia*, cxi.) so employs it. Dionysius, a priest of Alexandria, calls his bishop Papa Heraclius. St. Cyprian, in the letters of his clergy, is addressed *Beatissimo Papa Cypriano*. The same form is employed towards him by the clergy of Rome itself. Even Arius so addresses his own bishop Alexander. In the next century, St. Jerome addresses the same title to Athanasius, to Epiphanius, and most of all to Augustine. Indeed it would appear certain that down to the time of Gregory of Tours it was used not uncommonly of bishops in the Western Church. And there are evidences of its being occasionally applied to the inferior clergy, for whom, however, some adjunct was employed, in order to distinguish them from bishops. Thus, we sometimes read of *papa piscini*, minor popes; and the tonsure was called by the name *papa letra*. In the Greek Church, as is well known, whether in Greece Proper or in Russia, papa is the common appellation of the clergy. The circumstance of its having been originally of general application, is acknowledged by all learned Roman Catholic controversialists and historians.

PA'PACY. See POPES.

PAPAL STATES (Italian, *STATI DELLA CHIESA*, or *STATI PONTIFICI*), a territory or rather group of states in Central Italy, formerly united into one sovereignty, with the pope for its head. It was of an irregular form, resembling the letter Z, the upper portion lying to the east of the Apennines, the lower to the west of that range, these two being connected by a third strip, which crossed the peninsula from east to west. The P. S. were bounded on the N. by the Po, on the S. by Naples, on the E. by the Gulf of Venice and Naples, and on the W. by Modena, Tuscany, and the Tyrrhenian Sea. Detached portions, as Benevento and Pontecorvo, lay within the Neapolitan territory. The country is traversed by the Apennines, which attain their highest elevation in the Monte della Sibilla, which is about 7402 feet above sea-level. Owing to this range, which traverses the peninsula in the direction of its length, lying so much nearer the east than the west coast, the streams to the east of it have a short course and little volume, being, in fact, mere mountain torrents; while on the west side a few of the rivers are of considerable size. Of the latter, the Tiber (q. v.) is the largest. The eastern coast is bold and rugged, and destitute of proper harbors, that of Ancona alone excepted; towards the north, at the mouth of the Po, it gradually subsides into a low, level, marshy tract, with numerous lagunes. The country west of the Apennines is traversed by ranges of hills parallel to them, and gradually decreasing in elevation as they approach the sea. The coast itself is almost wholly flat, sandy, or marshy, with no deep bays and few good harbors besides Civita Vecchia. There are numerous small lakes, principally in the northern portion of the country, the chief of which are Lake Bolsena, Lake Perugia, and Lake Bracciano, the last an old crater, situated almost 1000 feet above sea-level.

The country was divided for administrative purposes into 20 districts, as follows: 1 Comarca, including Rome and the Agro Romano; 6 Legations, Bologna, Ferrara, Forli, Ravenna, Urbino, Velletri; and 13 Delegations, Ancona, Ascoli, Benevento, Camerino, Civita Vecchia, Fermo, Frosinone, Macerata, Orvieto, Perugia, Spoleto, Rieti, Viterbo; with a total area of 15,774 English square miles, and a population of above 3,000,000. The Legations of Bologna, Ferrara, Forli, and Ravenna constituted the *Romagna*; Spoleto and Perugia were known as *Umbria*; and Ancona, Fermo, Macerata, and Ascoli constituted the *March of Ancona*. The inhabitants, with the exception of 16,000 Jews, were of Italian race, and of the Roman Catholic religion. The only provinces which latterly remained under the papal rule were, Rome with the Comarca, the legation of Velletri, and the delegations of Civita Vecchia, Frosinone (excepting Pontecorvo), and Viterbo, with a total area of 4493 English square miles, and a population of about 700,000. The chief cities and towns in the territory were Rome (the capital), Viterbo, Velletri, Alatri, and Civita Vecchia.

Climate and products.—The climate of the P. S. is one of the finest in the world, and the heat of summer is tempered by the mild and cooling sea-breezes; but in the flats south of the Po and in the Campagna of Rome, the noxious atmosphere produced by the exhalations from the marshes is most destructive of human

life. Fever and ague are very prevalent among the inhabitants of the neighboring districts, and notwithstanding the attempts to remedy the deadly influence of the marshes by drainage and cultivation, it has hitherto been undiminished (see *MAREMMA*). Violent siroccos are occasionally experienced on the west coast. The northern portion, from its elevation, is exposed to severe cold during winter. The soil of the P. S. is in general extremely fertile; but the higher mountain districts are either quite barren, or only adapted for pasture; and not more than one-third of the whole surface is under cultivation.

The practice of agriculture is in its most primitive state, notwithstanding the fact that agriculture, as a science, originated here, and was practised for many centuries before it was introduced into the other countries of Europe; but the many political changes and revolutions which have convulsed the country, have acted as a bar to all enterprise. It must, however, be mentioned, that the present pope has, by salutary enactments, and by the establishment of agricultural societies, done much for the improvement of this branch of industry. The products are similar to those of the rest of Italy. The manufactures are comparatively unimportant—silks, woollens, and leather are the chief; but plate-glass, rope, sailcloth, cotton goods, paper, artificial flowers, wax-candles, soap, stoneware, &c., are also manufactured in various places. The fisheries are important. The chief minerals are alum, vitriol, saltpetre, sulphur, coal, rock-salt, marble, and alabaster.

Many of the manufactured goods, and wine, olive oil, wool, hemp, tobacco, bread-stuffs, catgut, &c., were exported, the total exports amounting to about £2,600,000, while the imports reached nearly £14,000,000. The statistics were latterly very unreliable, but the fact that the P. S. are now no more, renders details of trade under pontifical rule a matter of little importance. Indeed, no information on such topics were issued under the latest years of the political power of the pope.

Government.—The pope possessed absolute and unlimited power, but the members of the college of cardinals, who elected him, generally kept the chief offices of state in their own hands, and assisted the pope in the government of his states, as well as in the affairs of the church. The secretary of state was at the head of political affairs, and was nominated by the pope. He presided over both the ministerial council and the council of state. The former council, which consisted of five or more ministers, heads of departments, selected by the pope, had a voice in legislation, and also the right of authoritative interpretation of the laws; the latter, which consisted of thirteen members, also nominated by the pope, had, in matters of legislation and finance only the right of giving advice; but it settled any question of competency that might arise between the various branches of the administration. After 1850, there was also a separate *finanzi-consulta* for the regulation of financial affairs. The Comarca, which was more directly under the central government, was ruled by a cardinal president; the Legation was ruled by a cardinal-legate, aided by a provincial chamber of deputies. There were civil and criminal courts in all the provinces, minor courts in the communes, with courts of appeal in all the chief cities, and a central tribunal at Rome. All the proceedings of these courts were public, except trials for political offences.

The papal army, which formerly amounted to 20,000 men, in June 1863, numbered only 8513 men, infantry, cavalry, artillery, &c. included, and a considerable portion of the papal territory was garrisoned by French troops, without whose aid the pope's power could not have been maintained.

The income and expenditure for 1859, the last year of the entirety of the P. S., were respectively 14,453,325 scudi (£3,126,028), and 15,019,346 scudi (£3,248,088); but the three succeeding years showed a widely different result; the expenses being largely increased by the cost of the war, while from the rebellious provinces scarcely any taxes were collected. The income and expenditure for these three years were nearly as follows:

	Expenditure.	Income.
1860.....	£4,720,809	£1,716,658
1861.....	4,291,644	1,716,658
1862.....	2,145,822	1,072,911

The finances continued in the same deplorable condition, and the national debt amounted to about £17,000,000. The tax known as 'Peter's pence,' which was collected from all the Roman Catholic countries, had produced at the beginning of 1863 about £1,080,000.

History.—During the rule of the Goths and Lombards in Italy, the inhabitants of Rome and all who desired to live free from the barbarian yoke, feeling that the Greek empire was incapable of protecting them, and at the same time observing the pertinacity and energy with which the pope asserted the importance and dignity of Rome, naturally looked up to him as in some sort a protector; and it is to the gradual growth and spread of this feeling that the important position subsequently taken by the popes as authorities in temporal matters is chiefly due. About 720 A.D.,

Gregory III., having quarrelled with the Emperor Leo the Isaurian, declared the independence of Rome. In 726, Pepin le Bref compelled the Lombard king to hand over Ravenna, Rimini, Pesaro, Fano, Cesena, Urbino, Forlì, Comacchio, and fifteen other towns, to the pope, who now assumed the state of a temporal sovereign. Pepin's example was followed by his son Charlemagne; but, notwithstanding, the pope's sovereignty was more nominal than real, as the towns were not in his possession, and he only obtained a small share of their revenues. In the 11th c., the Normans greatly aided to increase the papal temporal authority, and in 1053 the duchy of Benevento was annexed.

In 1102, the Countess Matilda of Tuscany left to the pope her fiefs of Parma, Mantua, Modena, and Tuscany; but these were immediately seized by the German emperor, and of this magnificent bequest only a few estates came into the pope's hands. Between this period and the end of the 13th c., the popes succeeded, often by unscrupulous means, in obtaining from many of the free towns of Italy an acknowledgment of the superiority of the Roman see over them; and in 1278 the Emperor Rodolf I. confirmed the popes in the acquisitions thus obtained, defined authoritatively the boundaries of the P. S., and acknowledged the pope's exclusive authority over them, by absolving their inhabitants from their oath of allegiance to the empire. The P. S. at this time included Perugia, Bologna, Bertinoro, the Duchy of Spoleto, the Exarchy of Ravenna, and the March of Ancona; but many of the towns were either republics or hereditary principalities, and in none did the pope possess real authority. Sixtus IV., in the end of the 15th c., managed to annex the Romagna to his dominions; in effecting which he is accused of having employed intrigue, perjury, and murder. His successors, Alexander VI. and Julius II., increased the P. S. by the addition of Pesaro, Rimini, Faenza, Parma, Piacenza, and Reggio. By the victory of the French at Marignan (1515), the very existence of the papal power was threatened; but the able policy of Leo X. averted the threatened danger. In 1545, Paul III. alienated Parma and Piacenza, and erected them into a duchy for his son, Pietro Luigi Farnese; but this loss was partly made up by the acquisitions of Gregory XIII. In 1598, the possessions of the House of Este, viz., Ferrara, Comacchio, and a part of the Romagna, were seized by Pope Clement VIII.; and the P. S. received their final additions in Urbino (1623), Ronciglione, and the duchy of Castro (1650). The Romagna was seized by Napoleon in 1797, and incorporated in the Cisalpine Republic; and in the following year, Rome was taken by the French, and the P. S. erected into the *Roman Republic*.

Pius VII., in 1800, obtained possession of his states, but they were almost immediately retaken by the French, and finally (1809) incorporated with France, Rome being reckoned the second city of the empire. In 1814, the pope returned to his dominions, and was formally reinstated by the treaty of Vienna, mainly through the exertions of the *non-Roman Catholic* powers, Russia, Prussia, and Britain; but the clerical misgovernment contrasted so strongly with the liberal administration of France, that in 1830 the people of Ancona and Bologna rose in rebellion. They were put down by the aid of an Austrian army, but the abuses in the administration were so flagrant, that even Austria urged the necessity for reform. Her remonstrances, however, were not attended to, and the Bolognese again rebelled. This second revolt supplied Austria with a pretext for occupying the northern Legations, and the French at the same time garrisoned Ancona. Occasional risings took place from time to time up to 1846, when Pope Pius IX. assumed the tiara, and burst upon the astonished world in the new character of a reforming pope. His projects were of a most liberal character, and were put in force with great energy, despite the opposition of Austria; but, alarmed at the spread of revolution in Europe during 1848, he halted in his career, just at the critical moment when to halt was to be lost. The people rose, and Pius IX. fled to Gaeta, whilst Rome was proclaimed a republic. He was restored, and his subjects reduced to submission by the arms of France, Austria, Naples, and Spain.

The Austrians held the Legations in subjection to the pope's authority till 1859; and the French occupied Rome in his behalf for ten years more. In July 1859, the four northern legations (the Romagna), taking advantage of the withdrawal of the Austrian troops, quietly threw off the papal authority, and proclaimed their annexation to Sardinia, which was formally acknowledged by Victor Emmanuel in March 1860. The pope now raised a large body of troops, appointing Lamoricière, an eminent French general, to command them, for the purpose of resisting any further encroachments on his dominions; but the news of Garibaldi's success in Sicily and Naples produced revolt in the Legation of Urbino and in the Marches, the people proclaiming Victor Emmanuel. The Sardinians accordingly marched into the P. S., defeated Lamoricière in two encounters and finally compelled him to retire into Ancona, where, after a siege of seven days, he was compelled to surrender with his whole army. The revolted provinces of Umbria, Urbino, and the Marches were immediately annexed

to Sardinia; and the isolated provinces of Benevento and Pontecorvo (a part of Frosinone), which were situated within the kingdom of Naples, shared the same fate. In October 1870, the French having withdrawn, the remnant of the P. S. voted for annexation to the kingdom of Italy.

PAPAVERACEÆ, a natural order of exogenous plants, herbaceous or half shrubby, usually with a milky or colored juice. The leaves are alternate, without stipules; the flowers on long one-flowered stalks. The fruit is pod-shaped or capsular; the seeds numerous. The order is distinguished for narcotic properties. Opium (q. v.) is its most important product. The juice of *Celandine* (q. v.) is very acrid. A number of species are used in their native countries for medicinal purposes. The seeds yield fixed oil, which, with the exception of that obtained from *Argemone Mexicana*, is quite bland. See **POPPY**. The flowers of many species are large and showy, most frequently white or yellow, sometimes red. Several kinds of Poppy and *Eschscholtzia* are frequent in our gardens. There are in all about 130 known species, natives of all quarters of the world, and of tropical and temperate climates, but they abound most of all in Europe.

PAPAW' (*Carica Papaya*), a South American tree of the natural order *Papayaceæ*—of which order about 30 species are known—which has now been introduced into many tropical and subtropical countries. It grows to the height of 15–30 feet, with leaves only at the top, where also the fruit grows close to the stem. The leaves are 20–30 inches long. The fruit is of a green color, very similar in appearance to a small melon, and with a somewhat similar flavor. It is eaten either raw or boiled. The seeds are round

Papaw Tree (*Carica Papaya*).

and black, and when chewed, have in a high degree the pungency of cresses. The powdered seeds and the juice of the unripe fruit are most powerful anthelmintics. A constituent of this juice is *Fibrine*, otherwise unknown in the vegetable kingdom, except in the Fungi. The milky juice of the tree is very acrid. The leaves are used by negroes instead of soap to wash linen. The juice of the fruit and the sap of the tree have the singular property of rendering the toughest meat tender in a short time. Even the exhalations from the tree have this property; and joints of meat, fowls, &c., are hung among its branches to prepare them for the table. It is a tree of extremely rapid growth, bears fruit all the year, and is exceedingly prolific. The fruit is often cooked in various ways.—The *Chamburu* (*C. digitata*), another species of the same genus, a native of Brazil, is remarkable for the extremely acrid and poisonous character of its juice, and the disgusting stercoraceous odor of its flowers.—In the middle and southern states of America the name P. is given to the *Uvaria* (or *Asimina triloba*), a small tree of the natural order *Anonaceæ*, the fruit of which, a large oval berry, three inches long, is eaten by negroes, but not generally relished by others. All parts of the plant have a rank smell.

PA'ENBURG, a small town of Hanover, in the bailiwick of Osnabrück, on a canal navigable for sea-going vessels, 27 miles south-south-east of Emden, on Dollart Bay, by the Emden and Hanover Railway. It originated in a small colony which sprung up here, and was supported principally by peat-cutting, an employment for which the fens and moors of the vicinity afford abundant facilities. The town is cleanly built, after the Dutch model; its houses stretch along the canal banks. It possessed, in 1881, about 190 ships, and carries on manufactures of sail-cloth and ropes. Its commerce is considerable. Pop. (1880) 6736.

PAPER. This well-known fabric is usually composed of vegetable fibres minutely divided and recombined in thin sheets, either by simple drying in contact, or with the addition of size or some other adhesive material. Probably the earliest use of paper was for the purpose of writing upon, and its earliest form was the Papyrus (q. v.) of the Egyptians. The stems of the papyrus plant, which are often eight or ten feet long, are soft and green, externally like the common rush; and the interior consists of a compact cellular tissue or pith. At the bottom of each stem the portion immersed in the mud and water is whiter and more compact; and under the outer skin a number of thin pellicles lie one above the other. These were removed, and laid side by side with their edges overlapping each other, and crosswise upon these was placed one or more similar layers, until the sheet was sufficiently thick; pressure was then applied for a time, and afterwards the sheet was dried in the sun. The width of such sheets, of course, depended upon the length of the portion of papyrus stems taken; but they could be made any length by joining a number of the squares end to end by glue or any other adhesive material. The *scapus*, or roll, usually consisted of about 20 of them.

Owing to the fact that the various layers of the papyrus decrease in thickness as they are nearer to the center of the stem, the makers were enabled to produce papers of different qualities; and in the time of the Romans many varieties were known, which differed as to the quality of the material, and the size of the pieces of which the sheets were composed. The finest quality was made from the innermost layer of membrane, and was called *Hieratica*, or paper of the priests. This was made for the Egyptian priests, who interdicted its sale until covered with sacred writing. In this state it was, however, an article of trade, and the Romans found a means of removing the writing, and sold the palimpsest sheets in Rome under the name of *Augustus paper*, used as a Latin equivalent for its former Greek name of *hieratica*. It was, however, supposed by many that it was named after the Emperor Augustus, and in consequence a second quality was called after his wife, *Livinia*; and the original name of the first quality came in time to be applied to the third quality. The next quality was called *Amphitheatratica*, it is supposed, from its having been made in the vicinity of the Alexandrian amphitheater. This last, when imported to Rome, was partly remanufactured by Q. Remmius Fannius Palæmon, the schoolmaster and paper-maker, who, by a peculiar process of his own, reduced its thickness, and rendered it equal to the first quality, when it was sold under the name of *Fanniana*. There were other inferior qualities, of which one called *Emporetica* was used as shop-paper.

Pliny, from whom we get these very interesting particulars, tells us that all these kinds were manufactured in Egypt, and required the Nile water for their formation. He says, that 'when it is in a muddy state it has the peculiar qualities of glue, and the various kinds of paper are made on a table where they are moistened with this water. The leaves or sheets of membrane are laid upon it lengthwise, as long indeed as the papyrus will admit of, the jagged edges being cut off at either end; after which a cross layer is placed over; the same way, in fact, that hurdles are made. When this is done, the leaves are pressed together, and dried in the sun.' The idea of the adhesive quality of the Nile water is erroneous, but it is very probable the Egyptian manufacturers encouraged the error. It is obvious the whole merit consisted in using the membranes fresh, whilst their own natural gum was in proper condition to make them adhere together.

In India and China, the art of writing with a style or sharp point upon dried palm and other leaves, and also some kinds of bark, is common even at the present day, especially in Ceylon, where we find it common to employ the leaves of the talipot and other palms as paper. Perhaps it was from the employment of these materials, or it is even possible from watching the operations of the paper-making wasps and other insects, that the manufacture of larger pieces, by pulping the materials and spreading them out to a greater extent, was suggested. Whatever was the true origin of the art, it is now lost in the vista of time.

It is known that the Chinese were acquainted with the art of making paper from pulp artificially prepared as early as the commencement of the Christian era; and it is thought they used the bark of various trees, the soft parts of bamboo stems, and cotton. In the 7th c., the Arabians learned the art of making it of cotton from the Chinese, and the first manufactory was established, about 706 A.D., at Samarcand. From thence it was transported to Spain, where, under the Moors, paper was made not only of cotton, but it is thought also of hemp and flax. The exact time of the introduction of paper made of linen rags is very uncertain; but the best evidence is offered by the Arabian physician Abdollatiph, who writes, in an account of his visit to Egypt in the year 1200, 'that the cloth found in the catacombs, and used to envelop mummies, was made into garments, or sold to the scribes to make paper for shopkeepers'; and as there is no doubt that these mummy-cloths were linen, it proves that the use of this material is of no mean antiquity. Of the use of linen

rags in Europe, the earliest proof is in the celebrated document found by Ichwandner in the monastery of Goss, in Upper Styria, which purports to be a mandate of Frederick II., emperor of the Romans, and is dated 1242. It is written on paper which has been proved to be made of linen. The practice of making a distinctive water-mark on the paper, by means of an impression on the fine sieve of threads or wires upon which the floating pulp is received (fig. 4), was also of very early date, as MSS. as old as the 13th c. bear it. But there is really no satisfactory information respecting the exact time or place of the introduction of paper-making into Europe; by some it is supposed that Spain was the first to receive the art, and that thence it spread to France and Holland, and afterwards to England. It is quite certain that England was a long time behind these countries. As a proof of this, we find that the first patent for paper-making was taken out in 1665, by one Charles Hildeyer, but it was for 'The way and art of making blew paper used by sugar-bakers and others.'

The second was in 1675, by Eustace Barneby, for 'The art and skill of making all sorts of white paper for the use of writing and printing, being a new manufacture, and never practised in any way in any of our kingdoms or dominions.' This, then, was the first commencement of the making of writing and printing paper; but that it did not equal the manufactures of other countries is shown by the specification of another patent, taken out by John Briscoe in the year 1685, which is thus expressed: 'The true art and way for making English paper for writing, printing, and other uses, both as good and as serviceable in all respects, and especially as white as any French or Dutch paper.' As a general rule, it was the custom of paper-makers to employ linen rags for fine papers, but a great variety of other materials have been in use from its first introduction; for as early as 1680, Nathaniel Bladen took out a patent for 'An engine method and mill, whereby hemp, flax, linnen, cotton, cordage, silke, woollen, and all sorts of materials' might be made into paper and pasteboard; and from that time innumerable efforts have been made to prepare other materials than cotton and linen rags for the manufacture of paper. The following is a summary of the patents which have been taken out in Britain for making paper from various materials, with the dates, which will show to those engaged in this investigation in what directions the inquiry has been previously conducted. The arrangement is alphabetical, and consequently not in the order of dates.

Materials.	Names of Inventors, and Dates of Patents.
Aloe Fibre.....	Berry, 1838; D'Harcourt, 1838; Small, 1838; May, 1852; Burke, 1855.
Asbestos.....	Maniere, 1853.
Bagging or Sacking....	Stiff, 1853; Wheeler & Co., 1854; Ros-siter & Co., 1854; Smith & Co., 1855.
Banana Fibre.....	Berry, 1838; Lilly, 1854; Jullion, 1855; Burke, 1855; Hook, 1857.
Barks of various kinds.	Koops, 1800; Balmano, 1838; Nerot, 1846; Couplier, 1852; Johnson, 1855; Kelk, 1855; Lotteri, 1855; Niven, 1856; Broad, 1857; Hope & Co., 1857.
Bass or Bast.....	Ruck and Touche, 1856; Touche, 1857.
Bean-stalks, &c.....	D'Harcourt, 1838; Brooman, 1855.
Cane (Sugar).....	Berry, 1838; Couplier, 1852; Johnson, 1855; Jullion, 1855; Ruck & Touche, 1856; Hook, 1857.
Cocoa-nut Fibre.....	Newton, 1852; Holt and Forster, 1854.
Cocoa nut Kernel.....	Diaper, 1854.
Clover.....	Coupland, 1854; Holt and Fraser, 1854; Plunkett, 1857.
Cotton.....	Bladen, 1682; Williams, 1833; Couplier, 1852; Crossley, 1854; Sibley, 1857.
Dung.....	Jones, 1805; Zander, 1839; Lloyd, 1852; Hill, 1854.
Esparto or Alfa.....	Routledge, 1856.
Flax.....	Bladen, 1682; Koops, 1800; Jones, 1805; Ball, 1817; Berry, 1838; Gibbs, 1833; De la Garde, 1825; Couplier, 1852; Collins, 1853; Pownall, 1852; Coupland, 1854; Broad, 1857.
Flax, New Zealand....	Berry, 1838; Gibbs, 1833 and 1857; Gill-man, 1854.

Wrack Grass or Zostera	Spoooner, 1857.

But whatever the material employed, the process for nearly all is the same. The rags, bark, fibres, or other substance, have to be reduced with water into a fine smooth pulp. This, in the early stages of the manufacture, was accomplished by macerating and boiling the material, until, in the case of bark, fibres, or other raw material, the fibres could be drawn out from the cellulose matter, after which it was beaten with mallets, or with pestles in mortars, or stampers moved by some power. Water is generally used, but in Holland wind-mills do this work. The beating is continued until the material is reduced to a very smooth pulp. The pulping, in our machine paper-mills, is much more rapidly accomplished by boiling the linen or cotton rags, or other material in a strong lye of caustic alkali. This effectually cleans the rags, and other vegetable fibres are softened and separated in a remarkable manner by it; they are then put into a machine called the washing-machine (fig. 1), which washes out dirt and everything but the pure vegetable fibre. This machine (figs. 1, 2, and 3) is a large cast-iron vessel, usually about 10 feet in length, 4½ feet in width, and 2½ in depth. In the middle, occupying about two-

thirds of its length, is a partition, always cast with it, called the mid-feather, *a* (figs. 1 and 2), to support the axle or driving-shaft,

Fig. 1.

b (figs. 1 and 2). This turns the cylinder *c* (fig. 1), which has a large number of teeth or ridges running across it, which grip and tear the rags, or other materials, as they are drawn under it by the current formed by its revolutions. In order to facilitate this,

Fig. 2.

a peculiar form is given to the bottom of the part in which the cylinder works, as seen in fig. 3. The rise, *a* (fig. 3), is called the back-fall, and the materials are drawn up to, and through the

Fig. 3.

narrow space at *b*, by the current; then, as they pass over the rigid surface, *c*, they come in contact with the rigid surface of the cylinder, and are thus violently ground and drawn through, the stream carrying them round and round until they are thoroughly washed, and partly pulped, or as it is technically called, *broken in*.

The washing-machine is supplied with a continued flow of clean water, and the soiled water as regularly escapes through a fine gauze screen, in the ends of the cylinders, in which is an ingenious arrangement for raising it and carrying it away through the axis, which is hollow. The contents of the washing-machine are then allowed to flow out through a large valve, opening downwards into the draining-chest. Here the water is drained away, and the *stuff* is then placed in the bleaching vats, which are made of stone, and each calculated to contain a hundredweight of stuff, which is here submitted to the action of a strong solution of chloride of lime for about twenty-four hours, and frequently agitated; after which it is transferred to a hydraulic press, and pressed so as to remove the greater portion of the liquid and chloride of lime. It is then placed in another washing-engine, and for an hour is submitted to the same process as in the first; by which all vestiges of the bleaching materials are removed, and the stuff so much more broken down as to be called *half-stuff*. From this engine it is let out by a valve, and finds its way into the *beating-engine*, which is placed at a lower level so as to receive it. Here the arrangement is nearly the same as in the washing and intermediate engines; but the ridges on the bars below the cylinder, and on the cylinder itself, are much sharper, and the disintegration of the fibres is carried on with great rapidity until

they are quite separated; and the flow of the water in a rapid current, as it passes the cylinder, draws them out and arranges them in the water in much the same way as wool or cotton is laid on the carding-cylinders of a carding-machine. This operation takes about five hours, at the end of which time the materials have been worked up with the water into an almost impalpable pulp. This is then let out into the pulp vat, where it is kept continually agitated by a wooden wheel revolving in it, called a *hog*, and from this the hand-workman or machine is supplied.

We will now suppose the pulp formed and ready for use in the vat, and will first describe the process of hand-making, as formerly practised in all countries, and still in use, more or less, in all paper-making countries. The workman or vatman takes an implement called a *mould*, which consists of a sheet of very fine network, attached to a frame, as in fig. 4. In Europe this net-

Fig. 4.

Fig. 5.

work was always made of very fine wire; but in India, China, and Japan it is usually made of fine fibres of bamboo, which the workmen of these countries split and weave with remarkable skill. There are usually two kinds of moulds employed. In one, as in fig. 4, the wires are woven across each other, forming a very fine gauze, and paper made with them is known as *wove*. In the other, there are several cross-bars in the frame, and straight wires are laid from side to side, and about four or five to each half sheet are laid across them lengthwise, to keep them in position; the transverse wires are about twenty to the inch; the longitudinal ones are a little more than an inch apart. Paper made on such moulds is called *laid*, and is easily known by the impression of the wires upon it. Whichever kind of mould is used, another implement called the *deckle* (fig. 5) is required. It is a thin frame, which exactly corresponds to the frame of the mould, and the workman first places the deckle on the mould, and then dips them into the pulp; the deckle forms a ridge which retains just enough of the liquid pulp for the sheet of paper. The water of the pulp speedily drains through the wire gauze, and after it has stood in an inclined position for a few minutes, another workman, called the *coucher*, applies the face of the sheet of pulp to a piece of felt or flannel cloth stretched on a board, called the *couch*, and the sheet thus pressed, leaves the mould, and is left on the *couch*. Every successive sheet is similarly treated, and they are piled one on another, with a sheet of felt between each, until from four to eight quires, or a *post*, as it is called, is formed. Each post is put in a press, and under pressure parts with nearly all the moisture in the sheets of paper. The felts are then removed, and after several pressings, and other minor operations, the paper is hung on hair ropes, called *tribbles*, in the drying-loft; and when dried, resembles blotting-paper, and cannot be written upon. This is remedied by dipping it in a weak solution of hot size, sometimes tinged with color, after which it is pressed, dried, folded, and made up into quires. Hot pressing and glazing are done by passing the sheets through hot and polished iron rollers.

In Britain very little paper is now made by hand, the paper-machine having changed the character of the manufacture. It is usually stated that Louis Robert, a Frenchman, invented the paper-machine, and that it was brought to this country by Didot of Paris in an imperfect state, but received improvements from Fourdrinier. But it must not be overlooked that Bramah took out a patent in 1805, rather more than a year before Fourdrinier, for very similar improvements to those described in Fourdrinier's specification. The object of all was to cause an equal supply of the pulp to flow upon an endless wire-gauze apron, which would revolve and carry on the paper until it is received on an endless sheet of felt, passing around and between large couching cylinders. These machines have now been brought to such perfection, that paper can be made in one continuous web of any length; and before leaving the machine, is sized, dried, calendered, hot-pressed, and cut into sheets. Different engineers have contrived variations of construction in the paper-machine, but the general principles of all are the same. We therefore select for illustration the machine which was exhibited by Mr. George Bertram of Edinburgh, and which was universally acknowledged to be by far the most complete and perfect which was presented in the International Exhibition of 1862. Since then no very important improvements have been made in the main part of the machine, but the drying portion has been greatly extended.

Fig. 6 is a side view of the machine, and fig. 7 a vertical one. The principle of the machine is very simple; it contains a pulp vat, A (figs. 6 and 7), with a hog or wheel inside to agitate the

Fig. 6.

pulp, and an arrangement for pouring the pulp over the wire-gauze mould, B, B, B, B, which instead of being in single squares, as in the hand-process, is an endless sheet moving round two roll-

ers, *a, b*, which keep it stretched out and revolving when in operation. Under the part which receives the pulp there is a series of small brass rollers, *d* (fig. 6), these, being nearly close together, keep it perfectly level, which is a most necessary condition; besides which, there is a shallow trough *ee* (fig. 6), called the *save all*, which catches and retains the water, which always escapes with some pulp in suspension; and an arrangement of suction boxes and tubes, *f, f, f* (fig. 6), worked by air-pumps, which draw much of the water out as the pulp passes over them. The pulp is kept from running over the sides by straps called the *deckles*, which are also endless bands, usually of vulcanized India-rubber, carried round moving rollers, so that they travel with the wire-gauze, and therefore offer no resistance to it. In addition to all this, the frame-work on which the surface of the wire-gauze rests has a shogging motion, or side-shake, which has an important effect in working the fibres together before the pulp finally settles down. When it reaches the *couching-rolls*, which press out most of the remaining moisture, and carry it forward to the first and second series of press-rolls by means of an endless web of felt which passes round them, the speed of these rollers and the travelling sheet of felt, *CC* (figs. 6 and 7), is nicely calculated, so as to prevent a strain upon the still very tender web of paper. Sometimes the upper rollers of these two series are filled with steam, in order to commence drying the web. The paper is now trusted to itself, and passes on, as indicated by the arrows, from the second press-rolls to the first set of *drying cylinders*, *DD* (figs. 6 and 7), where it again meets with a felt sheet, which keeps it in close contact with the drying cylinders, which are of large size, and filled with steam. Around these it passes, drying as it goes; is then received between the two *smoothing-rolls*, or damp calenders, which press both surfaces, and remove the marks of the wire and felt, which are until then visible on the paper. This is necessarily done before the drying is quite completed; and from the smoothing-rolls it passes to the second series of drying cylinders, *E* (figs. 6 and 7), where the drying is finished, and thence to the calenders, which are polished rollers of hard cast-iron, so adjusted as to give a considerable pressure to the paper, and at the same time a glossiness of surface. For writing-papers, the paper passes through a shallow trough of size after leaving the drying cylinders, and then passes over another series of skeleton cylinders, with fans moving inside, by which it is again dried without heat, and afterwards passes through the calenders.

Printing and other papers are usually sized by mixing the size in the pulp, in which stage the coloring materials—such as ultramarine for the blue tint of foolscap—are also introduced. Still following the paper web in the drawing (fig. 6), it is seen to pass from the calenders to another machine, *F*; this slits the web into widths, which are again cross cut into sheets, the size of which is regulated at will. The water-mark is impressed on machine-made paper by means of a fine light-wire cylinder with a wire-woven pattern; this is placed over the wire-gauze sheet upon which the pulp is spread, but near the other end of it, so that the light impression of the marker may act upon the paper just when it ceases to be pulp, and this remains all through its course. There are many other interesting points about the paper-machine, but their introduction here would rather tend to confuse the reader. Its productive power is very great; it moves at a rate of from 30 to 70 feet per minute, spreading pulp, couching, drying, and calendering as it goes, so that the stream of pulp flowing in at one end is in two minutes passing out finished paper at the other. It has been computed that an ordinary machine, making webs of paper 54 inches wide, will turn out four miles a day, and that the total production of all the mills in Britain is not less than 6,000,000 of yards or 3400 miles daily.

For very obvious reasons, the manufacture of paper has been localized on the banks of streams that afford an abundant supply of pure water for washing and pulping. Kent is celebrated for its paper-mills and for the fine quality of its paper, and is the chief county in this respect. Next follow Hertfordshire (where it was first commenced in England in 1490 by John Tate of Stevenage, of whom it is said in a book printed by Caxton,

Which late hathe in England doo make thya paper thynne,
That now in our Englyssh thys booke is printed inne;

and the same John Tate is mentioned in Henry VII.'s Household Book, under dates May 25, 1498 and 1499, 'for a rewarde geven at the paper-mylne,' and 'geven in rewarde to Tate of the mylne, 6s. 8d.'). Buckinghamshire, Oxfordshire, and Lancashire. It was introduced into Scotland in the year 1695, when a company was formed for carrying it on under 'Articles' signed at a general meeting held in Edinburgh, which articles are now in the Library of the British Museum. It has become a very important branch of manufacture; and not only is paper of a very fine quality made from rags and the new material Esparto, Alfa, or Spanish Grass (the *Lygeum Sparteum* of botanists), but also the manufacture of paper-machines is carried on most successfully both for foreign

and home use. Both of these manufactures are carried on in the immediate neighborhood of Edinburgh.

Since the introduction of the penny postage, penny papers, and other economical measures, especially the abolition of the excise-

Fig. 7.

duty, an enormous impetus has been given to this branch of our home-manufacture, and considerable difficulty has been found in supplying the makers with raw material: this difficulty has been much increased by the export duties laid by other countries upon

the export of rags. The greatest relief has been experienced by improved methods for preparing paper pulp from straw, and from the introduction of the Esparto, which yields half its weight of paper. Of this material our imports have risen to 190,000 tons per annum, which represents 95,000 tons of paper. The imports of rags, notwithstanding the foreign impediments, are also very large. During the five years ending in 1875, they were as follows: 1871, 26,868 tons; 1872, 22,254 tons; 1873, 16,151 tons; 1874, 17,232 tons; 1875, 15,879 tons. In 1880, the 29,642 tons imported were valued at £451,782. Judging from good data, this manufacture has more than trebled since the abolition of the paper-duty, at which time it was very nearly 100,000 tons, a quantity so vast, that it will remove all surprise at the difficulty of supplying the raw materials.

The following are the principal varieties of ordinary paper, and the sizes of the sheets given in inches:

1. *Writing and Printing Papers.*—*Pot* (so named from its original water-work, a tankard), 12½ by 15; *Double Pot*, 15 by 25. *Foolscap*, 16½ by 13½; *Sheet-and-third Do.*, 22½ by 13½; *Sheet-and-half Do.*, 22½ by 13½; *Double Do.*, 27 by 17. *Post* (so called from its use in letter-writing; one of its original water-marks was a postman's horn), 18½ by 15½; *Large Do.*, 20½ by 16½; *Medium Do.*, 18 by 22½; *Double Do.*, 30½ by 19. *Copy*, 20 by 16½; *Double Crown*, 20 by 30. *Demy*, 20 by 15; *Printing Do.*, 22½ by 17½; *Medium Do.*, 22 by 17½; *Medium Printing Do.*, 23 by 18½. *Royal*, 24 by 19; *Printing Do.*, 25 by 20; *Super-royal*, 27 by 19; *Super-royal Printing*, 21 by 27. *Imperial*, 30 by 22. *Atlas*, 34 by 26. *Columbier*, 34½ by 23½. *Elephant*, 28 by 23; *Double Do.*, 20½ by 40. *Antiquarian*, 53 by 31; this is generally, if not always, hand-made.

These sizes are somewhat lessened by ploughing and finishing off the edges previous to sale.

2. *Coarse Papers for wrapping and other purposes.*—*Kent-cap*, 21 by 15; *Bag-cap*, 19½ by 24; *Havon-cap*, 21 by 16; *Imperial-cap*, 22½ by 29. *Double 2-lb.*, 17 by 24; *Double 4-lb.*, 21 by 31; *Double 6-lb.*, 19 by 28. *Cartridge, Casing, and Middle-hand*, &c., 21 by 16. *Lumber-hand*, 19½ by 22½; *Royal-hand*, 20 by 25; *Double Small-hand*, 19 by 29.

Purple papers of a soft texture, unsized, are used in very large quantities by sugar-refiners, of the following sizes: *Copy-loaf*, 16½ by 21½; *Powder-loaf*, 18 by 26; *Double-loaf*, 16½ by 23; *Single-loaf*, 21½ by 27; *Lump*, 23 by 33; *Hambro'*, 16½ by 23; *Titler*, 29 by 35; *Prussian*, or *Double Lump*, 32 by 42.

Blotting and Filtering Paper.—This is unsized paper, made of good quality, and usually colored pink or red, and of the same size as demy.

Besides these, which are well-known trade definitions, there are very many others, amounting, if we include *paste and mill boards*, to at least twelve or fifteen hundred, so that even paper-manufacturers require the aid of a treatise upon the subject of the sizes, qualities, &c., and such a treatise is in common use.

Even as regards materials, varieties are endless. In an old German book by Jacob Christian Schäffers, published at Regensburg in 1772, there are no less than eighty-one samples of different kinds of paper bound up and forming part of the book, and innumerable others have been made since.

Rice paper is a beautiful material imported from China, about which numberless errors have been written. It is now known to be formed of thin slices of the pith of the plant called *Aralia papyrifera*. This pith can be obtained from the stems in beautiful cylinders, from one to two inches in diameter, and several inches in length. The Chinese workmen apply the blade of a sharp, straight knife to these cylinders of pith, and, turning them round dexterously, pare them from the circumference to the center, making a rolled layer of equal thickness throughout. This is unrolled, and weights are placed upon it until it is rendered perfectly smooth and flat. Sometimes a number are joined together to increase the size of the sheets. It will be seen that this more nearly resembles the ancient papyrus than modern paper; but it is more beautiful than the former, being a very pure pearly white, and admirably adapted to the peculiar style of painting of the Chinese.

The ordinary papers of the Chinese, Japanese, and East Indians have much resemblance to each other, which arises from the manufacture and material being similar; the bark of the paper mulberry (*Broussonetia papyrifera*) being chiefly used. The Chinese and Japanese are the most skillful paper-makers in the world, and some of the East Indian papers surpass the European manufactures completely.

Some useful kinds of paper are the result of manipulations subsequent to the paper-maker's work. Thus:

Lithographic Paper is prepared from good printing-paper by laying on one side of the sheets a preparation consisting of six parts of starch, one of alum, and two of gum-arabic dissolved in warm water, and applied whilst hot with a proper brush. Generally a little gamboge is added, to give it a slight yellow color.

Copying Paper, for manifold-writers, is made by applying a composition of lard and black-lead to one side or both of sheets of

writing-paper; and after leaving it on for a day or so, it is carefully and smoothly scraped off and wiped with a soft cloth.

Tracing Paper is good printing-paper rendered transparent by brushing it over with a mixture of Canada balsam and oil of turpentine, or nut oil and turpentine. In either case it must be carefully dried before using.

There are two distinct classes of colored papers. In one, the color is introduced into the pulp, and is consequently in the body of the paper; in the other, the colors are mixed with size, and applied to the surface. There have been many ingenious and tasteful inventions for decorating the surface of paper, such as by giving it a marbled and even a beautiful iridescent appearance, but they are too numerous for the limits of this article.

Paper is subject to much adulteration. China-clay and gypsum are generally used for the white sorts, and the heavy ferruginous ochres for the coarse and brown kinds.

PAPER-BOOK, in English Law, is the name given to the pleadings on both sides in an action at law, when the issue is one, not of fact, but of law.

PAPER-HANGINGS. This name is applied to the webs of paper, *papiers peints* of the French, usually decorated, with which interior walls are often covered. Previous to the invention of the paper-machine, sheets of paper of the size called *Elephant*, 22 by 32 inches, were pasted together, to make 12 yards length, before the pattern was imprinted; but this is now rendered unnecessary by the facility of making webs of any length. Upon the paper it is usual first to spread a ground-color, with proper brushes, taking care to produce a perfectly smooth surface. The colors employed are opaque, and are mixed with size, and sometimes also with starch, and most of the ordinary pigments are used. In the early stages of the art, it was usual to have the patterns stencilled (see STENCILLING) on the ground-color. The stencilling plates were usually pieces of pasteboard, one being required for every differently-colored portion of the pattern. Afterwards, wooden blocks were adopted, similar to those used in calico-printing, made of pear or poplar wood, generally the width of the paper, forming, indeed, huge woodcuts, on which the pattern is in high relief. As many blocks are required as there are colors in the pattern, each bearing only so much of the pattern as is represented by the color to which it is assigned. Of course, the whole beauty of the work depends upon the nice adjustment of one portion of the pattern to another; and this is determined by guide-pins in the blocks, which are so managed as not to disfigure the surface with their points.

The pattern-block, being coated with its particular color from the color-tub, is laid on the paper, which is stretched out for the purpose on a table, and a lever is brought to bear upon it with sufficient pressure to make the whole of the block bear equally upon the paper. When one block has been printed the whole length of the paper by a succession of impressions, the piece is taken to the drying-room, and dried, previous to receiving the next color; and it often happens that the same operations have to be repeated a dozen different times before the pattern is completed. This process is now being rapidly superseded by the cylinder printing-machines, which are of the same kind as are used in printing textile fabrics. In these machines, the pattern is engraved on a series of copper cylinders, and each part or color has a separate cylinder, and an arrangement for keeping it constantly supplied with color when working. The cylinders are so arranged as, by the sum of their revolutions, to make the pattern complete; so that as the web of paper passes the first, it receives the color for one portion of the pattern, and reaches the second in exact time to have the next color applied in the right places. In this way the entire piece only occupies a few seconds in receiving the complete decoration.

The polished or glazed papers have the ground prepared with gypsum or plaster of Paris, and the surface dusted with finely-powdered steatite, or French chalk. When perfectly dry, this is rubbed hard with a burnishing-brush, until the whole is evenly polished. This is generally done before the pattern is printed, but in some cases pattern and ground are both polished. In making the *flock-papers*, the printing is done in the same way as in the block-printing, only, instead of colored material, a composition called *encaustic* is printed on. It consists of linseed-oil, boiled with litharge, and ground up with white-lead; sufficient litharge is used to make it dry quickly, as it is very adhesive. The flock is prepared from the shearings of woollen cloths from the cloth-mills, by washing and dyeing the shearings to the various colors, then stove-drying and grinding them in a peculiar mill, which, in their brittle state, after leaving the stove, breaks them short. After this they are sifted, to obtain various degrees of fineness. By nice management, the prepared flock is so sprinkled over the whole of the printed surface as to coat the encaustic, and adhere evenly and firmly to it. The same adhesive material is used for printing in gold and other metals. The pattern being printed with the encaustic, gold or other metallic leaf

is applied, and when it is properly fixed, the loose metal is brushed away with a hare's-foot or other soft brush. Some of the finest French papers have much of the pattern actually painted in by hand, a process which, of course, renders them very costly.

PAPER MULBERRY. See MULBERRY.

PAPER NAUTILUS. See ARGONAUT.

PAPHLAGONIA, anciently a province of Asia Minor, extending along the southern shores of the Black Sea, from the Halys on the east, to the Parthenius on the west (which separates it from Bithynia), and inland on the south of Galatia. Its limits, however, were somewhat different at different times. The Paphlagonian mountains were covered with forests, and the inhabitants were famous as hunters. Croesus made P. a part of the kingdom of Lydia, and Cyrus united it to Persia; it subsequently became part of the empire of Alexander the Great, and afterwards of the kingdom of Pontus, was included in the Roman province of Galatia, and in the 4th c. of the Christian era was made a separate province by Constantine. Its capital was Sinope. The Paphlagonians are supposed to have been of Syrian, or at least of Semitic origin, like the Cappadocians. They were proverbially rude, coarse, and deficient in understanding, but this probably refers only to the country-people in the interior.

PA'PHOS, anciently the name of two cities in the isle of Cyprus. The older city, sometimes called *Palaipaphos* (now *Kuklos* or *Komublia*), was situated in the western part of the island, about 1½ miles from the coast. It was probably founded by the Phœnicians, and was famous, even before Homer's time, for a temple of Venus, who was said to have here risen from the sea close by, whence her epithet *Aphrodite*, 'foam-sprung,' and who was designated the Paphian goddess. This was her chief residence, and hither crowds of pilgrims used to come in ancient times.—The other Paphos, called *Neopaphos* (now *Baffa*), was on the sea-coast, about seven or eight miles north-west of the older city, and was the place in which the apostle Paul proclaimed the gospel before the proconsul Sergius.

PA'PIAS, Bishop of Hierapolis in Phrygia, was a Christian writer, who flourished in the 2d century. According to Irenæus, he was a disciple of the apostle John; but Eusebius, who quotes (*Historia Ecclesiastica*, chap. 39) the words of Irenæus, immediately subjoins a passage from P. himself, in which the latter distinctly states that he did not receive his doctrines from any of the apostles, but from the 'living voice' of such followers of theirs as 'are still surviving.' He was, however, an 'associate' of Polycarp, a bishop in the same province of proconsular Asia; and as the latter was a disciple of the apostle John, it is probable that Irenæus—a somewhat hasty writer—inferred that his companion must have been the same. The *Paschal or Alexandrian Chronicle* states that he suffered martyrdom at Pergamus, 163 A.D. Eusebius describes P. as 'well skilled in all manner of learning, and well acquainted with the Scriptures,' but a little further on, he speaks of him as a man 'of limited understanding' (*smikrōs on tōn noîn*), and a very credulous chronicler of 'unwritten tradition,' who had collected 'certain strange parables of our Lord and of his doctrine, and some other matters rather too fabulous.' The work in which these were contained was entitled *Logion Kuriakon Eregéseos Biblia E'*. (Five Books of Commentaries on the Sayings of our Lord). It is now lost, but certain fragments of it have been preserved by Irenæus, Eusebius, Maximus Confessor, and other writers. These fragments are extremely interesting, because of the light which they throw on the origin of the New Testament Scriptures, and their importance may be estimated from the fact, that they contain the earliest information which we possess on the subject. It is P. who is our authority for the statement, that the evangelist Matthew drew up a collection of our Lord's sayings and doings (*ta logia*) in the Hebrew (probably Syro-Chaldaic or Aramaic) dialect, and that every one translated it as he was able.

There can be no doubt that this is a perplexing statement, suggesting as it does the delicate question: 'If Papias is correct, who wrote our present Matthew, which is in Greek, and not in Hebrew?' (For a consideration of this point, see MATTHEW.) P. also tells us, either on the authority of John the Presbyter, or more probably on that of one of his followers, that the evangelist Mark was the interpreter (Hermeneutes) of Peter, and wrote 'whatsoever he [Peter] recorded, with great accuracy.' But the passage is far from implying that Mark was a mere amanuensis of Peter, as some have asserted, but only, as Valesius has shown, that Mark listened attentively to Peter's preaching, culled from it such things as most strictly concerned Christ, and so drew up his gospel. P., it remains to be said, was an extreme millenarian. See MILLENNIUM.

PAPIER-MACHÉ (Fr. mashed or pulped paper). This manufacture has certainly been in use for more than a century in Europe; but it is not improbable that it was first suggested by some of the beautiful productions of Sinde and other parts of

India, where it is employed in making boxes, trays, &c., as well as in China and Japan. Its first application, as far as we know, was to the manufacture of snuff-boxes by a German named Martin, in 1740, who learned it of a Frenchman named Lefevre; but the French say that he learned the art in England. Properly speaking, papier-maché is paper-pulp moulded into shape, and it has been used, not only to make small articles, such as boxes, trays, &c., but in the interior decoration of houses for cornices, ceilings, &c. The ceilings in Clueterfield House, and some other fine Elizabethan structures, are made of this material, which at one time, owing to a combination of the stucco-workers to raise the price of their labor, took the place almost entirely of stucco in house ornamentation.

At present, a combination of both stucco and paper is similarly employed under the name of *Carton-pierre*. From the extension of the applications of papier-maché to the manufacture of a number of light and useful articles, modifications have taken place in its composition, and it is now of three kinds—1st, the true kind, made of paper-pulp; 2d, sheets of paper pasted together after the manner of pasteboard, but submitted to far greater pressure; and 3d, sheets of thick millboard cast from the pulp are also heavily pressed. The term papier-maché is in trade held to apply rather to the articles made of the pulp than to the pulp itself; and a vast manufacture has sprung up during the present century, particularly in Birmingham, in which a great variety of articles of use and ornament are made of this material. They are coated with successive layers of asphalt varnish, which is acted upon by heat in ovens until its volatile parts are dissipated, and it becomes hard, and capable of receiving a high polish. Mother-of-pearl is much used in their decoration, for which purpose, when several layers of the varnish still remain to be applied, thin flakes of the shell of the form of the pattern are placed on the varnish, and are covered by the succeeding layers, giving rise to elevations where they are hidden by the coats of varnish. The surface is then ground down smooth and polished, and the grinding down brings to light the pieces of mother-of-pearl shell, which thus present the appearance of inlaid patterns. The fine surface which can be given to the asphalt varnish, also permits of burnished gilding and other decorative applications with excellent effect.

PAPILIO. See BUTTERFLY.

PAPILIONA'CEÆ, a suborder of the natural order of plants generally called *Leguminosæ* (q. v.).—The plants of this suborder are the only plants known which have flowers of the peculiar structure called *papilionaceous*, and of which the Pea and Bean afford familiar examples. The name is derived from Lat. *papilio*, a butterfly. Papilionaceous flowers have five petals, imbricated in estivation (bud), one of which, called the *ocellum*, or *standard*, is superior, turned next to the axis, and in estivation folded over the rest; two, called the *ala*, or *wings*, are lateral; and two are inferior, which are often united by their lower margins, forming the *carina*, or *keel*. The number of the P. is very great—about 4800 species being known. They are found in all parts of the world, abounding in the tropics. Many have superb and beautiful flowers; many are plants of beautiful form and foliage, trees, shrubs, or herbaceous plants; many possess valuable medicinal properties; and many are of great importance as furnishing food for man and for domestic animals, others as furnishing dyes, fibre, timber, &c. See BROOM, LABURNUM, CLOVER, BEAN, PEA, LUCERNE, LIQUORICE, INDIGO, SANDAL-WOOD, &c.

PAPIL'LLÆ. This term is applied by anatomists to minute, elongated, conical processes, projecting from the surface of the true skin into the epidermis, highly vascular and nervous in their character, and taking an active part in the sense of touch. Their form and structure are described in the article SKIN. The mucous membrane of the tongue also contains three varieties of papillæ, which are described in the article TASTE, ORGAN AND SENSE OF.

PAPIN, DENIS, a celebrated French physicist, was born at Blois, 22d August 1647, and studied medicine in Paris, where, after receiving his degree, he practised for some time as a physician. He now became acquainted with Huyghens—an incident which strengthened in him an original predilection for physical science; and from this time, he devoted himself almost exclusively to his favorite study. Before P.'s time, the intense force which can be generated in water, air, &c., under the action of heat, was well known, but he was one of the first to indicate the principal features of a machine by which this property could be made of practical utility. He soon acquired a wide reputation; and on visiting England was received with open arms by the philosophers of that country, and became a member of the Royal Society in 1681. While in England P. & Boyle (q. v.) together repeated their experiments on the properties of air, &c.; but in 1687, P. was called to the chair of Mathematics in the university of Marburg, in Hesse-Cassel. In 1696 he went to live in the town of Cassel; and in 1707 he came to London. He died in poverty and neglect in 1712. The French Academy of Sciences, withholding from P. the honor of 'associate,' enrolled him among

its 'correspondents'—a proceeding on the part of the Academy which has, with reason, excited the astonishment of F. Arago. To P. undoubtedly belongs the high honor of having first applied steam to produce motion by raising a piston; he combined with this the simplest means of producing a vacuum beneath the raised piston—viz., by condensation of aqueous vapor; he is also the inventor of the 'safety-valve,' an essential part of his 'Digester' (q. v.) By this latter machine, P. showed that liquids in a vacuum can be put in a state of ebullition at a much lower temperature than when freely exposed to the air.

P.'s sagacity led him to many other discoveries; he discovered the principle of action of the siphon, improved the pneumatic machine of Otto de Guericke (q. v.), and took part against Leibnitz in the discussion concerning 'living' and 'dead' forces. Unfortunately for science, P.'s numerous writings have not yet been collected, but many of them will be found in the *Philosophical Transactions*, *Acta Bruditorum*, and the *Recueil de Diverses Pièces*. He published two works—one being an explanation of the construction and uses of his 'digester' (Lond. 1681), afterwards (1682) translated into French, and his experiments entitled *Nouvelles Expériences du Vide* (Paris, 1674). It was not till nearly a century after that the great value of P.'s discoveries was perceived. See his *Life* by Gerland (Berlin, 1881).

PAPINIA'NUS, **ÆMILIUS PAULLUS**, the most celebrated of Roman jurists, was born towards the middle of the 2d c.; and during the reign of the Emperor Severus (q. v.), whom he succeeded as *Advocatus Fisci*, and whose second wife is said to have been P.'s relative, he held the office of *Libellorum Magister*, and afterwards that of *Prefectus Prætorio*. After the death of Severus, his son and successor, Caracalla, dismissed P. from his office, and soon afterwards caused him to be put to death on various pretexts, the real reason, however, appearing to be that the emperor was afraid the influence of a man so able and upright would be dangerous to his power. P.'s works consist chiefly of 37 books of *Questiones*, 19 of *Responsa*, 2 of *Definitiones*, two works, *De Adulteriis*, and a Greek fragment; and from these works there are in all 595 excerpts in the Digest (q. v.).

The pupils of P. include the most famous names in Roman jurisprudence, such as Ulpian, Paullus, Pomponius, Africanus, Florentinus, and Modestinus, but the master stands superior to them all. The high reputation he enjoyed among his contemporaries and successors may be gathered from the epithets *Prudentissimus*, *Consultissimus*, *Disertissimus*, bestowed upon him by various emperors, and from the first book of the *Codex Theodosii*, *De Responsis Prudentum*, in which, after declaring the works of P., Paullus, Caius, Ulpian, Modestinus, and four others, to be authority for a judge's decision, it is declared that should these jurists be equally divided in opinion, that opinion which was maintained by P. was to be considered right; while his commentator, the celebrated Cujacius (q. v.), goes so far as to declare 'that Papinianus was the first of all lawyers who have been, or are to be,' and that 'no one ever will equal him.' His high reputation as a jurist was much enhanced by the strong moral feeling and stern unbending honesty which were equally characteristic of him, and which have stamped his works with an ineffaceable impress. P.'s works were studied both before and after Justinian's time by Roman legal students of the third year, who were for this reason denominated *Papinianistæ*. The fragments of P.'s works which now remain are somewhat obscure, and the excerpts from them in the Digest are in general so brief, that the aid of a commentator is required.

PAPIST (Lat. *papista*, an adherent of the pope) is a name applied, generally with some admixture of contempt, to members of the Roman Church. Of itself, it implies nothing more than that they are adherents of the pope; but in its popular use it includes all the distinctive doctrines of Roman Catholics, and especially those which are supposed to be peculiarly cherished by the supporters of the papal authority. It is therefore in many cases held to be synonymous with the profession of the extreme opinions permitted in the Church of Rome, and even those which are popularly regarded as superstitious. Understood literally, no consistent Roman Catholic would disclaim it; but in the imputed signification explained above, it is held to be offensive.

PAPPENHEIM, **GOTTFRIED HEINRICH**, COUNT VON, an imperial general of great note in the Thirty Years' War, was born at Pappenheim, in Middle Franconia, Bavaria, 29th May 1594, of a very ancient Swabian family, in which the dignity of Marshal of the Empire became hereditary about the 15th or 14th c., and many of whose members had greatly distinguished themselves in the wars of the middle ages. When about 20 years of age, P. went over to the Roman Catholic Church, and thenceforth signalized himself by his fiery zeal in its cause. After serving under the king of Poland in his wars with the Russians and Turks, P. joined the army of the Catholic League, and in the battle of Prague (1620) stayed the flight of the Austrian cavalry, and by a well-timed and furious charge turned the tide of battle against the

Bohemians. In 1623, he received from the emperor the command of a cavalry regiment of the famous 'Pappenheimer Dragoons'; and in 1625, became general of the Spanish horse in Lombardy; but in 1626 re-entered the Austrian service, and after suppressing a dangerous revolt of the peasants of Upper Austria, in which 40,000 of the peasants perished, he joined the army which was opposed to the Protestant league, and, in association with Tilly, carried on many campaigns against the Danes, Swedes, and Saxons. It was P. who urged and induced Tilly to take Magdeburg by assault, and himself led and directed the attack. Moreover, it is he, rather than Tilly, who was to blame for the ferocious massacres which followed. His reckless bravery involved Tilly, against his will, in the disastrous battle of Breitenfeld; but to some extent he retrieved his character by his strenuous efforts to remedy the loss, and protect the retreat of the army. After Tilly's death, he was associated with Wollenstein, who detached him with eight regiments to protect Cologne, but on hearing of the advance of Gustavus, sent an urgent order for his return.

P. arrived at Lutzen at the moment when Wallenstein's army was on the point of being completely routed, and at the head of his cuirassiers charged the left wing of the Swedes, throwing it into confusion, and almost changing the fortune of the battle by his extraordinary bravery. He was mortally wounded in the last charge, and died a few hours afterwards at Leipzig, November 7, 1632, with a smile on his countenance, after learning that Gustavus Adolphus had died before him. 'God be praised!' he said; 'I can go in peace, now that that mortal enemy of the Catholic faith has had to die before me.'

PA'PPUS, in Botany, an appendage of the fruit of plants belonging to certain natural orders, of which the great natural order *Compositæ* is the chief. It consists either of simple (figs. 1 and 4) or feathery (figs. 2 and 5) hairs, sessile or stalked, arising from the summit of the fruit, and is produced by a development of the tube and limb of the persistent calyx. Its object appears to be to waft the ripened seed to the new situation in which it is to grow. Thistle-down is the pappus of the thistle.—The pappus is sometimes represented by mere teeth or scales.

Pappus: 1 and 2, sessile; 3, scale-like; 4 and 5, stalked.

PAPPUS of Alexandria, one of the later Greek geometers, of whose history nothing is known; he is said by Suidas to have lived during the reign of Theodosius the Great, emperor of the East (379–395). Some writers are of opinion that he lived two centuries earlier, but the former is much the more probable opinion. The chief work of P. is his *Mathematical Collections*, of which the last six, out of eight books, are extant. The *Collections*, as their name implies, are an assemblage into one book of scattered problems and theorems, the work of Apollonius, Archimedes, Euclid, Theodosius, &c., to which he has joined his own discoveries.

The first two books are supposed (on insufficient grounds) to have treated of arithmetic and arithmetical problems, but only a small fragment of the second book is extant: the third book is a collection of problems, mostly of solid geometry: the fourth treats of curves other than the circle, according to the method of pure geometry: the fifth contains problems of maxima and minima: the sixth treats of the geometry of the sphere: the seventh, which is by far the most important to modern geometers, as it is almost the sole authority we possess on the subject of the history and methods of the Greek geometrical analysis, treats principally of analysis; it also contains the proposition now known as 'Guldinus' Theorem,' which was plagiarized from P. by Father Guldin: the eighth and last book treats of machines. P. was the author of several other works which are lost, excepting only a fragment of his *Commentary on Four Books of Ptolemy's Syntaxis*. P., as an independent investigator, enjoys a high reputation, and is considered by Des Cartes as one of the most excellent geometers of antiquity. Some of his problems have been looked upon with high interest by all succeeding geometers. The *Mathematical Collections* have been published in whole or part, at various periods, but the only complete editions are the two Latin versions, the first by Commandine (Pisa, 1588), and the second by Manolesius (Bologna, 1660), and the Greek edition of H. J. Eisenmann (Paris, 1824). The portion of the Greek text of the 2d book, which was wanting in Commandine's MS., was published (1888) in London by Dr. Wallis.

PAPU'Ā, or **NEW GUINEA**, is, with the exception of Australia, the largest island on the globe. It lies in lat. 0° 30'–10° 40' S., and long. 131°–150° 30' E., and is about 1300 miles in length. In outline the island is very irregular, the western part being nearly insulated by Geelvink Bay, on the north, and M'Clure's Inlet

from the west. The head of Geelvink Bay is separated from the south coast by an isthmus only 35 miles in breadth. Eastward from this, the island increases in breadth from 200 to 360 miles, and terminates in the south-east, in a narrow peninsula of lofty mountains. The area is given by Wallace at 300,000 square miles.

There is probably no region on the globe so little known as P.; the coast has not even been visited in some parts, and the maps published to this date show unsurveyed portions. It is not known with certainty who discovered Papua. It is attributed to a Spaniard, Alvaro de Saavdra. To him the first detailed notice of the island is due, and it was he who first noticed the resemblance of the inhabitants to African negroes, and for that reason gave the country the name of New Guinea. In 1606, the Spanish frigate *La Amiranta*, Captain Luiz Vaes de Torres, made the island, and sailed along the southern shore to the strait that bears his name. In 1676, the Dutch captains, Schouten and Le Maire, landed on the island to obtain fresh water. They were unexpectedly attacked by the natives, who killed 18 of their men. M. de Bougainville, in 1768, also made the south coast of the island, and worked to windward along it. The English navigators, Cook in 1770, and Forrest in 1774, Edwards in 1791, and the following year Captain Bligh, of *Bounty* notoriety, saw portions of the south coast. Flinders, in 1799, visited the island, and added a few facts to our scanty information. In the course of the voyage of the French ship *Astrolabe*, under the command of J. Dumont d'Urville, the distinguished naturalists, Quoi and Gaymard, studied the natural history of the island, and more especially its zoology. A Dutch expedition in 1828 added to the information of the western coast.

In 1845, Captains Blackwood and Owen Stanley, of Her Majesty's ships *Fly* and *Bramble*, surveyed part of the southern coast; and between 1846 and 1850, the last-named officer surveyed the southern shores of the eastern peninsula. In 1858, the Dutch government sent a surveying expedition in the steamer *Etna* to the north and north-west coasts. In 1869, attention was called to our lack of information on P., and to the fact that so little had been done to explore this great and fertile island, which lay almost within sight of Australia, and might be looked on as belonging to that continent. Sir Charles Nicholson especially directed the attention of our Australian colonists to the importance of their becoming acquainted with the island, lying, as it does, on the highway to India and China, and believed to be rich in minerals and commercial products. In 1871, a Russian steam corvette left on the north-east shores the naturalist, Miklukho Maclay, who lived for 15 months there, and has repeatedly visited P. since. Meyer, and the Italian travelers Beccari and D'Alberis, have added much to our knowledge of the interior. The agents of the London Missionary Society have also extended our knowledge of the country. Early in 1873, H. M. S. *Basilisk*, Captain Moresby, was sent to suppress the system of kidnapping natives in the neighborhood of Torres Strait; and this being accomplished, Captain Moresby employed his time in continuing the survey of the eastern coasts commenced by Captain Owen Stanley. He found the eastern part of the island different in form from the representations as given on our maps, inasmuch as a considerable portion of the eastern promontory consisted of islands with deep channels between, instead of being a continuous line of coast. But little is known of the geography of the island beyond the coast. The northern side is hilly and densely covered with wood, whilst such portions of the southern coasts as have been visited are low, and apparently swampy, but still densely wooded.

A range of mountains, the Charles Louis Mountains, commences on the south coast near Geelvink Bay, and extends due east, rising gradually to a height of nearly 17,000 feet, where it is lost sight of at a distance of 100 miles from the coast; but it is not improbable that this range continues through, and subdivides the island until it joins the high land of the eastern peninsula, where a succession of mountains, from 14,000 to 5000 feet high, continue to the eastern extreme. A large island, Frederick Henry Island, 100 miles long by about 50 broad, on the south-west coast, was supposed to be part of the mainland until Lieutenant Kool, of the Dutch navy, passed through the strait that separated it. The London Missionary Society's agents, in their steamer the *Ellan-gowan*, have also lately found that what was considered the south cape of P. is detached from the mainland, and have called it Stacy Island. The Fly River has been ascended 160 miles by the same parties. The whole of the south-eastern coast to the eastern extreme of the island, and continuing to the Louisiade Archipelago beyond, is fringed with dangerous coral reefs, and as during the monsoons the currents acquire a great velocity, the danger of navigating is considerable. Captain Moresby has discovered a new passage at the south-east point of the main island, China Strait, which is navigable for large ships, and apparently free from dangers; it is considered that this discovery will lead to more rapid communication between China and Australia. The tides, however, at springs, run at the rate of 5 or six knots, but

more careful and elaborate surveys will doubtless render navigation more safe and expeditious in these waters.

There cannot be a doubt that in an island of such vast extent as P., not only does the character of the human family greatly diverge, but there may possibly exist several distinct races. With our little knowledge, two distinct races are admitted, viz., the Papuans, so called from the Malayan 'frizzled hair,' and the Haraforas. The Papuans are said to resemble the Australian aborigines, but, as a rule, are stouter. The Haraforas are distinguishable from the Papuans by lighter color and straighter hair; they also exhibit greater activity of body.

Except in the swampy districts, the climate is not unhealthy, though the temperature varies greatly, the thermometer sometimes indicating 95° F. by day, and falling to 75° by night. On the south-west coast, the east monsoon or rainy season begins about the middle of April, and ends in September; the dry season is from September to April, and on the north coast they are just reversed.

The island is everywhere clothed with the most luxuriant vegetation, cocoa-nut, betel, sago, banana, bread-fruit, orange, lemon, and other fruit-trees lining the shores; while in the interior are abundance of fine timber trees, as the iron-wood, ebony, canary-wood, the wild nutmeg, and the massoi, the fragrant bark of which is a leading article of export from the south-west coast. In the districts of the Arfak and Amberbakin Mountains the sugar-cane, tobacco, and rice are cultivated.

The natural history of the western part of P. has been recently examined by Mr. Wallace. This naturalist established the fact that a deep channel in the bed of the ocean, running west of Celebes, and east of the great islands of Java and Borneo, now known as Wallace's Line, separates two regions, in which the islands rise from shallow waters, and which are totally unlike each other in their botany and zoology. The islands on either side of this line he supposes to be the relics of submerged continents. Those on the west, or the Great Malay Islands, belong to the continent of Asia, and have its plants and animals. Those to the east of the line, on the other hand, including P., have a flora and fauna resembling those of Australia. The latter island has a dry climate and stunted vegetation. P., on the contrary, has a warm and moist climate, pre-eminently fitted to produce a varied, luxuriant vegetation; and it is clothed from end to end with magnificent forests. Insect life is, as night be expected, abundant and varied; the Papuan species being remarkable for fine forms and beautiful colors. Still more interesting to the naturalist is the variety of birds, of which 120 species are singers, 30 parrots, and 28 pigeons. Those of land species which have been examined belong to 108 genera, 29 of which are found exclusively in Papua. The beautiful birds of paradise are peculiar to the island, and distinguish it from all other regions. In contrast to this variety of birds is the small number of mammals. The great pachyderms and quadrupeds of the Malay Islands are wanting, and the mammals are 2 bats, 1 pig, 10 marsupials, 1 cetacea, and 1 carnivora. There is one true kangaroo similar to those of Australia. The climbing kangaroos take the place of the monkeys of the Asiatic area. It is believed that Wallace's Line, or one nearly coincident with it, separates two varieties of the human race, the Malays and the Papuans, or rather areas in which one of these races predominates.

Mr. Alfred Wallace, in his *Malay Archipelago*, says of the Papuans: 'There has been much difference of opinion about the races of the Oceanic region, but it is generally admitted that they belong to four different types—those of (1) the Malays; (2) the Negritos or Papuans; (3) the Polynesians; (4) the Australians. The most distinguished of recent ethnologists class the Malays with the Mongols; the Negritos or Papuans, and the Polynesians, with the negroes of Africa; and distinguish widely the Australians from both. They do not recognize any fundamental distinction between the dark Papuans and the light-complexioned Polynesians. The western parts of the island are inhabited by the former, the eastern parts by the latter. The Papuans are well made, have regular features, intelligent black eyes, small white teeth, curly hair, thick lips, and large mouth; the nose is sharp, but flat beneath, the nostrils large, and the skin dark brown. They are,' Mr. Wallace says, 'superior in stature to average Europeans, but have long and thin legs, and the splay foot of the negro.' He thinks the Papuans superior to the Malays in intelligence. In the western parts, they are divided into small distinct tribes, frequently at war with each other. The men build the houses, hollow the trunks of trees into canoes, hunt and fish; while the women do all the heaviest work, cultivating the fields, making mats, pots, and cutting wood. Their food consists of maize, sago, rice, fish, birds, the flesh of wild pigs, and fruits, &c. 'They are copper colored, of a light active build, often with very good features, which they paint; but the men's teeth and mouths are much disfigured by constant use of betel-nut. The hair is usually worn frizzled out into a huge mop.

The women's hair is always cut short. Their weapons appear

to be spears, swords, clubs, and stone hatchets, but no bows and arrows were seen amongst them. Occasionally human jaw and spinal bones are worn as bracelets and ornaments. They appeared to take pleasure in making us understand that they had eaten the original owners of the bones; but these bones, as well as the few skulls exhibited in their villages, appeared to be of an ancient date. The houses are built after the Malay fashion, on poles raised 5 or 6 feet above the ground, and consist of one large apartment. The natives of Humboldt's Bay have a temple in every village, though nothing is known of their religion.

In the eastern part of the island, the negro type of the inhabitants passes into that of the Polynesians. Captain Moresby says of them, that they have the light complexion and in all respects the appearance of the Polynesians, typically represented by the New Zealanders, that they are a friendly and intelligent people, and gladly receive the English seamen at their villages, where they mixed freely with them. They practise several useful arts, such as pottery, and possess extensive, well-fenced plantations. In the north-eastern part of the island, their villages are terraced and cultivated to a great height, in a manner which a Chinaman might envy. Captain Moresby believes them to be a fine, promising race, and thinks that, with the aid of civilizing influences, a prosperous future is in store for them.

The Dutch scientific expedition of 1858 appended to their report a vocabulary of the Myfore language, of about 1200 words, collected by Ottow and Geisler, missionaries at Doreh, on the west of Geelvink Bay. It is, however, known to differ greatly from languages spoken in other parts; and natives of the South Sea Islands have a facility in communicating with the Papuans on the Torres Strait. The London Missionary Society has therefore begun to Christianize them through Sannan teachers directed by British missionaries. The first chapel, on Murray Island, was opened in 1875. The population of P. and the immediately adjacent islands has been estimated at 800,000, but no correct estimate of the numbers can be formed. The exports are massoi bark, trepang or béche-de-mer, tortoise-shell, pearls, nutmegs, birds of paradise, crown-pigeons, ebony, resin, slaves, &c.

The inhabitants seem to be divided into a great number of petty tribes, quite independent of each other. No native government is known to extend over a great part of the island. The Dutch acquired the rights of their tributary, the sultan of Tidore, and it was partly to assert them that an expedition was undertaken in 1828. At this time, the Dutch built a fort called Du Bus, in Triton Bay, 8° 46' S. lat., and 184° E. long., and declared the whole island west of a line running from Cape Bonpland in the north, along 141° E. long., to Torres Strait, to belong to the Netherlands, but the settlement was abandoned. In 1858, the Dutch made another attempt to establish a colony. The *Etna* was fitted out for that purpose. The expedition visited a great part of the north-western coast. Recent attempts of parties of miners to tap the metallic treasures of P. have not as yet met with success.

That a great future is open to this vast territory is undoubted. Rich in natural products and mineral wealth to an extent of which we can have no conception, situated in such close contiguity to one of our largest possessions, and between it and China, Japan, and India, it is of immediate consequence to England; the western part may be regarded as under the Dutch power. In 1883, the government of Queensland annexed the eastern portion of P. in the name of the Queen of Great Britain and Ireland; but its action was not sanctioned by the Imperial government, greatly to the dissatisfaction of Queensland and the other Australian colonies. (The name P., commonly called *Pa'pua* in England, should be pronounced *Papoo'a*.)

PA'PULÆ AND PAPULAR DISEASES. Papulæ, or pimples, constitute one of the eight orders of Bateman and Willan's classification of cutaneous diseases. They occur as little elevations of the cuticle, of a red color, containing neither pus nor any other fluid, and ending usually in a scurf. They are generally supposed to denote inflammation of the papillæ of the skin; but Erasmus Wilson believes that they represent an inflammatory condition of the secretory orifices, whether sudoriferous or sebaceous. The diseases regarded as papular are Strophilus, Lichen, and Prurigo; but there are other diseases in which the first external symptom is a papular eruption, as, for example, small-pox, in which the papula speedily develops itself into a pustule.

PAPY'RI. Rolls made of the paper of the papyrus plant are commonly known as *papyri*, corresponding to the Greek *biblia*.

These rolls are of a very remote antiquity, some of the still remaining Egyptian papyri being certainly as old as the 6th dynasty, and others as old as the 12th, or from about 2000 B.C. This is owing to their mode of preservation, and to the peculiarly dry character of Egypt. These rolls have been found deposited in different ways, those of a religious nature being placed upon the bodies of mummies, at the feet, arms, or even in the hands, sometimes, indeed, packed or laid between the bandages, or even spread over the whole bandages, like a shroud. At the time of the 19th and 20th dynasties (1820—1200 B.C.), they were often deposited in hollow wooden figures of the god Ptah Socharis Osiris, or of the god Osiris, which were placed near the mummies.

Papyri of a civil nature were deposited in jars or boxes, which were placed near the mummies, or have been found in the remains of ancient libraries. The following are the principal kinds of Egyptian papyri: 1. Hieroglyphical papyri, always accompanied by pictures or vignettes, and consisting of three classes: 1. Solar litanies or texts, and pictures relating to and describing the sun's passage through the hours of the night, when that luminary was supposed to enter the Egyptian Hades or Hell. 2. Books of the empyreal gate, or heaven, with vignettes of deities, and other representations referring to the genesis of the cosmos or universe. 3. The so-called Ritual, consisting of a series of sacred or hermetic books, some of a very remote antiquity, accompanied with rubrical titles and directions as to their efficacy and employment, and comprising various formulas ordered to be placed on the coffins, amulets, and other furniture of the dead, for the better preservation of the souls of the dead and of the mummies in the future state. In this book, chapters giving an account of the future judgment of the *makheru*, or boat of the dead, of the Elysian Field, and of the Halls through which the dead had to pass, are also found. The work was considered by the Egyptians themselves mystic, and parts were supposed to be written by the god Thoth himself. A copy more or less complete, according to the wealth of the deceased, was deposited with all the principal mummies; and from the blank spaces left for the name, which was afterwards filled up, it is evident they were kept ready made.—II. Hieratic papyri, written in the hieratic or cursive Egyptian hand, comprising a more extensive literature than the hieroglyphic papyri.

This hand-writing being used for civil as well as religious purposes, the papyri found in it differ considerably from one another, and comprise rituals of the class already mentioned, principally in use about the 26th dynasty, or the 6th c. B.C., but found also on some few papyri of a remote period; a book called the *Lamentations of Isis*; magical papyri, containing directions for the preparation of charms and amulets, and the adjuration of deities for their protection; civil documents, consisting of the examination of persons charged with criminal offences, the most remarkable of which are that of an offender charged with the practice of magic in the 19th dynasty, another of a criminal charged with various crimes, in the reign of Sethos I., the examination of a conspiracy in the palace of Rameses II., and the *procos-verbal* of an offender charged with violating the sepulchres of the kings in the reign of Rameses IX. Besides these, there are several letters of various scribes upon subjects connected with the administration of the country and private affairs; laudatory poems of Egyptian monarchs, one describing the campaign of Rameses II. against the Khita or Hittites; historical documents, the journeys in foreign parts; the endowment of temples by Rameses III.; works of fiction, one of the adventures of two brothers, the death of the younger, owing to the false accusation of the wife of the elder, his revival, and transformation into a bull and a Persea tree; another the story of a doomed prince, and the adventures of different persons. Works on plants and medical subjects, books of proverbs, lists of kings, historical accounts, are amongst these documents.—III. The last class of Egyptian papyri, those written in the demotic or enchorial character, consist of rituals, contracts for the sale of mummies and lands, accounts and letters, and miscellaneous documents. These papyri are often bilingual, sometimes accompanied with hieratic or Greek versions. Many of these papyri have been translated by De Rouge, Chabas, Heatli, Goodwin, Birch, and others. Many Greek papyri have been found belonging to the archives of the Serapeion, referring to the administration of that temple, the orations of Hypereides, and some of the books of Homer. At all times in the history of Egypt, libraries of papyri seem to have existed, and, under the Ptolemies, are said to have contained as many as 700,000 rolls.

Another class of ancient papyri, those of Pompeii and Herculaneum, are of considerable interest, as showing the condition and arrangement of a Roman library. The papyri of Herculaneum are from 8½ to 12½ inches wide, and are rolled up in a cylindrical roll, *volumen*, upon a stick or inner roll, *bacillus*, *umbilicus*, having a stud at the end, *cornu*. They had their titles written on a strip, *lorum*, in red letters, and the writing was either on blind lines, or else on lines ruled with lead. About 1800 papyri were discovered at Herculaneum, in 1753, in the library of a small house, charred to a cinder, and some of these, by the greatest skill and

care, have been unrolled by a very laborious process at Naples. Unfortunately, they have not answered the literary expectations formed of them, consisting of the works of philosophers of the Epicurean school, which the proprietor of the library seems to have collected. Some of the papyri were in Latin, and more difficult to unroll. Many of them have been published. They are only written on one side. When a small number were required, they were placed in a cylindrical bronze chest (*cista*), packed tightly in a perpendicular position, and were taken out single, and read by unrolling from one end. These papyri were of various prices; old ones, like old books, being of immense value, but those containing the works of contemporary authors were not dearer, perhaps, than modern books. Many extensive private and public libraries existed in Greece and Rome, but all have perished except those exhumed from Herculaneum.

PAPYRUS, a genus of plants of the natural order *Cyperaceae* of which there are several species, the most important being the EGYPTIAN P. or *Papyrus* of the ancients (*P. antiquorum*, *Cyperus papyrus* of Linnaeus); a kind of sedge, 8 to 10 feet high; with a very strong, woody, aromatic, creeping root; long, sharp-keeled leaves; and naked, leafless, triangular, soft and cellular stems, as thick as a man's arm at the lower part, and at their upper extremity bearing a compound umbel of extremely numerous drooping spikelets, with a general involucre of 8 long filiform leaves, each spikelet containing 6—13 florets. By the ancient Egyptians it was called *papy*, from which the Greek *papyrus* is derived, although it was also called by them *byblos* or *deltos*. The Hebrews called it *gomé*, a word resembling the Coptic *gom*, or volume; its modern Arabic name is *Berdî*. So rare is the plant in the present day in Egypt, that it is supposed to have been introduced either from Syria or Abyssinia; but it has been seen till lately in the

Papyrus (*P. antiquorum*).

vicinity of the Lake Menzaleh, and specimens sent to England; and as it formerly was considered the emblem of Northern Egypt, or the Delta, and only grown there if introduced, it must have come from some country lying to the north of Egypt. It has been found in modern times in the neighborhood of Jaffa, on the banks of the Anapus, in the pools of the Liane, near Syracuse, and in the vicinity of the Lake Thrasymenus. It is represented on the oldest Egyptian monuments, and as reaching the height of about ten feet. It was grown in pools of still water, growing ten feet above the water, and two beneath it, and restricted to the districts of Sais and Sebennytus.

The P. was used for many purposes, both ornamental and useful, such as crowns for the head, sandals, boxes, boats, and cordage, but principally for a kind of paper called by its name. Its pith was boiled and eaten, and its root dried for fuel. The papyrus or paper of the Egyptian was of the greatest reputation in antiquity, and it appears on the earliest monuments in the shape of long rectangular sheets, which were rolled up at one end, and on which the scribe wrote with a reed called *kash*, with red or black ink made of an animal carbon. The process of making paper from the papyrus is described in the article PAPER. When newly prepared, it was white or brownish white and lissom; but

in the process of time, those papyri which have reached the present day have become of a light or dark brown color, and exceedingly brittle, breaking to the touch. While papyrus was commonly used in Egypt for the purposes of writing, and was, in fact, the paper of the period, although mentioned by early Greek authors, it does not appear to have come into general use among the Greeks till after the time of Alexander the Great, when it was extensively exported from the Egyptian ports under the Ptolemies. Fragments, indeed, have been found to have been used by the Greeks centuries before. It was, however, always an expensive article to the Greeks, and a sheet cost more than the value of a dollar. Among the Romans it does not appear to have been in use at an early period, although the Sibylline books are said to have been written on it, and it was cultivated in Calabria, Apulia, and the marshes of the Tiber. But the staple was no doubt imported from Alexandria, and improved or adapted by the Roman manufacturers. So extensive was the Alexandrian manufactory, that Hadrian, in his visit to that city, was struck by its extent; and later in the empire, an Egyptian usurper (Firmus, 272 A.D.) is said to have boasted that he could support an army off his materials. It continued to be employed in the Eastern and Western Empire till the 12th c., and was used among the Arabs in the 8th; but after that period, it was quite superseded by parchment. At the later periods, it was no longer employed in the shape of rolls, but cut up into square pages, and bound like modern books.

As a matter of scientific interest, experiments on the manufacture of paper from the P. have been made in recent times by Landolina, Seyfarth, and others.—Another species of P. (*P. corymbosus* or *P. Pangorei*) is much used in India for making mats. See INDIAN GRASS MATTING.

PAR or PARR, a small fish, also called BRANDLING and FINGERLING in different parts of Britain, inhabiting rivers and streams, and at one time believed to be a distinct species of the genus *Salmo*, but now almost universally regarded as the young of the salmon. The question will be noticed in the article SALMON. It may here, however, be mentioned, that it is difficult to discriminate the young of different species of this genus. The par rises with extraordinary readiness to the artificial fly; and until it began to receive protection as the fry of the salmon, vast numbers were killed both by youthful and adult anglers.

PARA', or BELE'M, a thriving city and seaport of Brazil, capital of the province of the same name, stands on the east bank of the river Para, 80 miles from its mouth. Lat. 1° 28' S., long. 48° 28' W. The harbor is formed by an abrupt curve or inlet of the channel of the river, which is here 20 miles broad. Vessels of large size are admitted; but the anchorage, though safe, has of late years become increasingly difficult of access, owing to the approaches getting silted up. The streets are paved and macadamized, but are for the most part in bad repair; the houses, like those of most Brazilian towns, have whitened walls and red-tiled roofs. Among the principal buildings are the palace, the cathedral and the churches. There are also numerous public squares, a college, and a beautiful botanic garden. The city is supplied with water by water-carts that perambulate the streets. The 'Amazon Navigation Company,' a Brazilian association, has erected large workshops, coal depôts, and wharfs; and steam navigation is rapidly extending. The imports have an annual value of about 5,000,000 dollars; the annual exports reach nearly 8,000,000 dollars, of which about 6,000,000 are for india-rubber. The imports are principally cotton manufactures, wheat and flour, cutlery and hardware, wool, gold and silver wares, coins, and wine. The exports are india-rubber, coffee, sugar, raw cotton, hides, tobacco, diamonds, and cocoa. Pop. 35,000.

P. is the mart through which passes the whole commerce of the Amazon and its affluents. The city was the seat of revolution during the whole of the year 1835, when a great number of lives were lost and houses destroyed, and grass grew in streets that previously had been the center of business. It is only since the year 1848 that the city can be said to have fairly entered upon the path of orderly commercial progress; and since that period, its advance has been continuous and rapid.

PARA', an important province of the empire of Brazil, in the extreme north of the country, is bounded on the N. by Guiana and the Atlantic, on the E. by Maranhão and Goyaz, on the S. by Matto Grosso, and on the W. by Amazonas. Area, 460,000 square miles; pop. (1872) 280,000. It is one of the largest provinces of Brazil—having an area nearly twice the extent of Austria—is watered by the Amazon and its great affluents the Tapajós, Xingú, and Tocantins; and forms a portion of a district—the Amazon Valley—which has been described by the most thorough explorer of this region as unequalled for richness of vegetable production and fertility of soil. The surface of the country is level, and consists of great plains, intersected by rivers, and covered with primeval forests, and in some cases with rich pasture. The climate, though warm, is not unhealthy. The precious metals, with diamonds, iron, and coal, are found, but are not worked. The

timber is valuable, and the chief crops raised upon the very limited area as yet brought under cultivation are coffee, rice, millet, and cotton.

'PARA', the name of the south arm of the Amazon, forming an outlet for that river into the Atlantic, on the southern side of the island of Marajo (q. v.). It is 200 miles in length, is 20 miles broad opposite the city of Para, and is 40 miles broad at its mouth. Its most important affluent, and the source whence it draws, perhaps, the great mass of its volume of waters, is the Tocantins. Formerly, the name Para, which is said to signify 'father of waters,' was applied in a general way to the river Amazon. At the time of the spring-tides, the *bore* rushes up the river with enormous force, forming a wave 15 feet high.

'PARA', a coin of copper, silver, or mixed metal, though most generally of copper, in use in Turkey and Egypt; it is the 40th part of a piastre, is divided into 3 aspers, and varies much in value, owing to the debased and complicated condition of the Turkish coinage. Pieces of 5 paras are also in use. The para is equal to about $\frac{1}{40}$ th of a penny sterling in Turkey, and $\frac{1}{16}$ th of a penny sterling in Egypt. See PIASTRE.

PARA GRASS. See PIASSABA.

PA' RABLE (Gr. *parabolē*, a comparison) was originally the name given by the Greek rhetoricians to an illustration avowedly introduced as such. In Hellenistic and New Testament Greek, it came to signify an independent fictitious narrative, employed for the illustration of a moral rule or principle. This kind of illustration is of Eastern origin, and admirable examples are to be found in the Old and New Testaments, particularly in the discourses of our Lord. It is no less interesting than curious to learn that many of Christ's parables, or at least much of his parabolic imagery, are to be found in the writings of Hillel, Shammai, and other great rabbis, as, for example, the parables of the Pearl of Great Price, the Laborers, the Lost Piece of Money, the Wise and Foolish Virgins, &c.

Among modern writers, the German divine Krummacker (q. v.) has greatly distinguished himself in this species of composition. The parable differs with the Fable (q. v.) in the probability or veri-similitude of the story itself, and agrees with it in the essential requisites of simplicity and brevity. In the course of time, the word parable came to lose its significance of figurative speech, and to mean speech generally. From the *parabola* of the Latin Vulgate, came the medieval Latin *parabolare*, whence the modern French *parler* and *parole*. An excellent work on the parables of the New Testament—probably the best in the English language—is that by Archbishop Trenc.

PARA'BOLA, one of the conic sections, is produced by a plane not passing through the vertex, which cuts the cone in a direction parallel to that of a plane touching the convex surface of the cone. A little consideration will show that a section so produced cannot be a closed curve, but its two branches, though continually widening out from each other, do not diverge so rapidly as in the Hyperbola (q. v.). The nearer the cutting plane is to that which touches the cone, the less do the two branches diverge; and when the two planes coincide, the branches also coincide, forming a straight line, which is therefore the limit of the para-

The diagram shows a parabola opening to the right. A horizontal line labeled AE represents the axis of symmetry, with point A at the vertex. A vertical line labeled CD represents the directrix. Point S is the focus on the axis. A point P is on the parabola. A line segment PS connects the point on the parabola to the focus. A line segment PD connects the point on the parabola to the directrix, perpendicular to it. A line segment SE is drawn from the focus perpendicular to the directrix. A line segment AO is drawn from the vertex perpendicular to the directrix. The diagram is labeled with a on the left, β at the top, and c at the bottom.

$ES = 2AS) \ 4AS + 4AS \cdot SN = 4AS (AS + SN) = 4AS \cdot AN$;
 and calling PN, the semiordinate, y ; AN, the abscissa, x ; and
 AS , a ; the equation to the parabola becomes $y^2 = 4ax$, where a
 (the distance of the vertex from the focus) remains the same for
 all points in the same curve. It is evident from the equation, as
 well as from the geometrical derivation of the parabola, that it
 must have two, and only two branches, and that the further it is
 extended the nearer its branches approach to the condition of
 straight lines parallel to the axis, though they never actually be-
 come so. The parabola has no asymptotes, like the hyperbola,
 but it possesses many properties which are common to it with
 that curve and the ellipse. In fact, the parabola is nothing more
 than an ellipse, whose major axis is infinitely long.

If parallel rays of light or heat fall upon the concave surface of a paraboloidal (see PARABOLOID) mirror, they are reflected to the focus, and conversely, if a light be placed in the focus of a paraboloidal reflector, its rays will be reflected in parallel directions, and would appear equally bright at all distances did light move without deviation, and unabsorbed. Also, if a body be projected in a direction not vertical, but inclined to the direction of gravity, it would, if undisturbed by the resisting force of the atmosphere, describe accurately a parabola whose axis is vertical, and whose vertex is the highest point reached by the body (see PROJECTILES).

The term *parabola* is used in analysis in a general sense, to denote that class of curves in which some power of the ordinate is proportional to a lower power of the abscissa. Thus, the curve we have just described, and which is distinguished as the *common* or *Apollonian parabola*, has the square of its ordinate proportional to its abscissa; the *cubical parabola* has the cube of its ordinate proportional to its abscissa; and the *semi-cubical parabola* has the cube of its ordinate proportional to the square of its abscissa.

PARABOLA NI (Gr. *parabolos*, a desperate person), a class of functionaries in the early church, by some writers reckoned as members of the clergy, and included in the ranks of the minor orders, but more probably religious associations, whose duty it was to assist the clergy, especially in the more laborious and the menial offices of religion or of charity. The etymology of the name is somewhat curious, being derived or applied from that of those desperate adventurers of the arena who hired themselves for the wild-beast fights of the amphitheater. The chief duty of the parabolanī was the tending of the sick, whether in ordinary diseases or in times of pestilence. By some, the association is believed to have originated at Alexandria, and perhaps to have been peculiar to that church; but although the parabolanī were certainly very numerous at Alexandria, amounting to some 500 or 600, it is beyond all question that they were also enrolled in other churches. We find them at Ephesus, at the time of the council in 449. They held the same place in regard of ministrations to the living, that the *Fossores* of Rome or the *Kopiatari* of the Greeks did in relation to the burial of the dead. The parabolanī are made the subject of formal legislation by Theodosius the younger. At first they were subject to the *Præfectus Augustalis*, but a later decree placed them directly under the authority of the bishop.

The name *parabolani* must not be confounded with the epithet *parabolarius*, which the pagans applied to the Christian martyrs, from the recklessness with which they gave their lives for their faith.

PARA'BOLOID, a solid figure traced out by a Parabola (q.v.) revolving round its principal axis. Sections of this solid parallel to the principal axis are parabolas, and those perpendicular to it, circles. The term 'paraboloidal,' for which 'parabolic' is frequently but improperly substituted, is applied either to bodies having the form of a paraboloid, or to concave surfaces which seem to have taken their peculiar hollow shape from the impress of a paraboloidal body.

PARACE'LSUS. About the end of the 15th c. there lived in the small town of Marien-Einsiedeln, near Zurich in Switzerland, William Bombast von Hohenheim, a physician and chemist; he was married to the lady-superintendent of the hospital attached to the convent of Einsiedeln; they had an only son, Philip Aureolus Theophrastus, born, it is thought, about 1493. The name Paracelsus, by which he is now known, is a rude rendering into Greek and Latin of his patronymic. It seems doubtful if he ever attended any regular school, but he received from his father the rudiments of Latin, and whatever else he could teach. He soon took to roaming, and even pursued his travels into Asia and Africa. How he maintained himself during his pilgrimage is unknown; probably by necromancy and quack cures—that is, proclaiming he had certain specifics, and bargaining for the amount he was to receive if he performed a cure. He was a diligent chemist, investigating the processes of the preparation of metals, and making experiments as to their medicinal virtues; also to discover the philosopher's stone. As a chemist he lived with Sigismund Fugger, one of a family celebrated for its patronage of art.

and science. His cures, real or pretended, became noised abroad, and he was called to prescribe for all the great men of his day.

When he was thirty-three, he boasted of having cured thirteen princes, whose cases had been declared hopeless. He was then at his zenith, and at the recommendation of Ecolampadius was appointed professor of physic and surgery at Basel. He commenced his academic career by publicly burning Galen's works, exclaiming Galen did not know as much as his shoe-latchets. 'Reading never made a physician,' he said; 'countries are the leaves of nature's code of laws—patients his only books.' His class-room at first was full to overflowing, but was soon deserted, and he fell into habits of excessive intemperance; indeed his secretary asserts he was drunk every day; never undressed, and went to bed with his famous sword by his side, which he would draw, and flourish about the room. The reason of his departure from Basel was, that a certain dignitary, suffering from gout, in his agony sent for Paracelsus, and promised to give him 100 florins if he cured him. Paracelsus gave him three *laudanum* pills; the canon felt comfortable, and the doctor claimed his fee, but the churchman refused to pay. Paracelsus took him into court, but the judge decided against the professor, who lost his temper, and abused the legal functionary in such a manner that the matter was taken up by the town council, and ended in the expulsion of Paracelsus. He recommended his wanderings. Wherever he went he excited the regular faculty to a state of violent hatred, not wholly undeserved. At Salzburg he had given offence in the usual way, and the result was, 'he was pitched out of the window at an inn by the doctor's servants, and had his neck broken by the fall.' This took place in 1541.

That a man whose life was such an incoherent medley should exert an influence for centuries after his death, may well be a matter of surprise, but he and the age were fitted for each other. He struck the weak point of the prevailing system of medicine; he appealed to the public as to whether it were not a false system that could only lead to failure, and he proposed a system of his own, which, though shrouded in absurdity and obscurity, inaugurated a new era of medicine. The prominent idea of his system is, that disease does not depend upon an excess or deficiency of bile, phlegm, or blood, but that it is an actual existence, a blight upon the body subject to its own laws, and to be opposed by some specific medicine. See the works of Paracelsus; also of Schulz (1831); Lessing (1889); Mook (Würzb. 1876); and Russell (*History and Heroes of Medicine*, 1861).

PA'RACHUTE (Fr. *chute*, a fall), a machine invented for the purpose of retarding the velocity of descent of any body through the air, and employed by aéronauts as a means of descending from balloons. It is a gigantic umbrella, strongly made, and having the outer extremities of the rods, on which the canvas is stretched, firmly connected by ropes or stays to the lower part of the handle. The handle of the parachute is a hollow iron tube, through which passes a rope connecting the balloon above with the car (in which are the aéronauts and their apparatus) beneath, but so fastened, that when the balloon is cut loose, the car and parachute still remain connected. When the balloon ascends, the parachute collapses like an umbrella; but when the balloon rope is severed, and the car begins to descend, the parachute is extended by the action of the air, and prevents the car from acquiring a dangerous velocity of descent; the final velocity in those cases where the machine is of a size proportioned to the weight it has to support, being no more than would be acquired by a person leaping from a height of between two and three feet. But the slightest derangement of the parachute's equilibrium, such as might be caused by a breath of wind, or the smallest deviation from perfect symmetry in the parachute itself, immediately produces an oscillatory motion of the car, having the apex of the parachute as a center, and the oscillations becoming gradually greater and more rapid, the occupants of the car are in most cases either pitched out, or are along with it dashed on the ground with frightful force.

This defect in the parachute has been attempted to be remedied in various ways, but hitherto without success. The first successful experiment with the parachute was made by Blanchard at Strasburg in 1787, and the experiment has been often repeated by Garnerin and others; very frequently, however, with fatal results.

The parachute was employed by Captain Boxer, R.N., as an essential part of his patent light-ball, for discovering the movements of an enemy at night, and was so arranged as to open up when the lighted ball had attained its greatest elevation, so as to keep it for a considerable period almost suspended in the air.

PARADE (from *parare*) signified in its original sense a prepared ground, and was applied to the courtyard of a castle, or to any enclosed and level plain. From the practice of reviewing troops at such a spot, the review itself has acquired the name of parade. In its modern military acceptation, a *parade* is the turning out of the garrison, or of a regiment in full equipment, for inspection or evolutions before some superior officer. It is the

boast of British troops that their line and discipline are as perfect under an enemy's fire as on the parade ground.

PA'RADISE. See EDEN.

PARADISE, BIRD OF. See BIRD OF PARADISE.

PARADOS—another name for Traverse—is an intercepting mound, erected in various parts of a fortification for the purpose of protecting the defenders from a rear or ricochet-fire. See FORTIFICATION.

PA'RADOX (Gr. *para*, beside, or beyond, and *doxa*, an opinion), a term applied to whatever is contrary to the received belief. Cicero, in his book on paradoxes, states that the Stoics called by this name all those unusual opinions which contradict the notions of the vulgar. It follows from this that a paradox is not necessarily an opinion contrary to truth. There have been bold and happy paradoxes whose fortune it has been to overthrow accredited errors, and in the course of time to become universally accepted as truths. It is, perhaps, even one of the prerogatives of genius to bring such into the world, and thereby to alter the character of an art, a science, or a legislation; but this, the highest form of paradox, which is only another name for originality of thought, or for novelty of scientific discovery, is rare. The paradox which springs from a passion for distinction, and which, in its efforts to achieve it, despises good sense and the lessons of experience, is far more frequent. It may not be at bottom a positive error in thought, but it is so exaggerated in expression, that if taken literally it actually does mislead. This is the besetting sin of the brilliant and epigrammatic class of writers, abundant examples of which are to be found in modern French literature.

PA'RAFFIN is the name given to several closely-allied substances, which are composed of mixtures of polymeric hydrocarbons, of the olefant gas series (that is to say, of the formula $C_{2n}H_{4n}$), and are obtained from the dry distillation of wood, peat, bituminous coal, wax, &c. P. is particularly abundant in beech tar, but according to Reichenbach, to whom its name (which is formed from *parum affinis*, 'little allied,' in consequence of its resisting the action of the strongest acids and alkalis) is due, and who may be regarded as its discoverer; it is also found in the tar of both animal and vegetable substances. At ordinary temperatures paraffin is a hard, white, crystalline substance, devoid of taste or odor, and resembling spermaceti, both to the touch and in appearance. The paraffin obtained from wood fuses at about 111°, but the varieties obtained from other substances have considerably higher boiling-points. When carefully heated, it sublimes unchanged at a little below 700°. It dissolves freely in hot olive oil, in oil of turpentine, in benzol, and in ether, but it is only slightly soluble in boiling alcohol, and is quite insoluble in water. It does not burn readily in the air, unless with the addition of a wick, when it evolves so brilliant and smokeless a flame that it has been applied to the manufacture of candles, which rival those made of the finest wax. The main supply of the paraffin of commerce is obtained in this country, from the Boghead canal-coal, and from the bituminous shale of West Calder. See NAPHTHA. A bituminous shale near Bonn supplies much of the continental demand.

PARAFFIN OIL is the term applied to the oily matter which is given off in large quantity in the distillation of Boghead canal-coal. By rectification it may be separated into three portions, one of which remains liquid at very low temperatures, boils at about 420°, and is much used under a variety of names for illuminating purposes, while a mixture of the two less volatile portions (which may be regarded as composed of paraffin dissolved in a mixture of hydrocarbons of nearly the same composition as paraffin) is largely employed for the purpose of lubricating machinery, for which it is admirably adapted by its power of resisting the oxidizing action of the atmosphere, and by its very slow evaporation. See NAPHTHA.

PARAGUAY', a republic of South America. Its frontiers, previous to the war of 1865–1870, were not well defined, but on its conclusion were fixed by treaty. P. now extends from 22° to 27° 30' S. lat., and from 54° 33' to 58° 40' W. long., forming the peninsula between the rivers Paraguay and Parana. It is bounded N. and N.E. by Brazil, S.E. S., and S.W. by the Argentine Confederation, and N.W. by Bolivia. Its area previous to the war was about 108,148 square miles, and is now variously estimated at from 57,000 to 90,000 square miles. Before the war, the population was variously estimated at from 450,000 to 1,300,000, consisting of whites of Spanish descent, native Indians, negroes, and a mixture of these several races. In 1873, it had fallen to 221,079; in 1876, it was 293,844. A mountain-chain called Sierra Amambay, running in the general direction of from north to south, and bifurcating to the east and west towards the southern extremity, under the name of Sierra Maracayú, divides the tributaries of the Parana from those of the Paraguay, none of which are very

considerable, although they are liable to frequent and destructive overflows.

The northern portion of P. is in general undulating, covered by low, gently-swelling ridges, separated by large grass plains, dotted with palms. There are mountains in the north-east and north-west corners. The southern portion is one of the most fertile districts of South America, consisting of hills and gentle slopes richly wooded, of wide savannahs, which afford excellent pasture-ground, and of rich alluvial plains, some of which, indeed, are marshy, or covered with shallow pools of water (only one lake, that of Ypoao, deserving special notice), but a large proportion are of extraordinary fertility and highly cultivated. The banks of the rivers Parana and Paraguay are occasionally belted with forest; but, in general, the low lands are destitute of trees. The climate, for a tropical country, is temperate, the temperature occasionally rising to 100° in summer, but in winter being usually about 45°. In geological structure, the southern part belongs generally to the tertiary formation; the north and east presenting greywacke rocks in some districts. The natural productions are very varied, although they do not include the precious metals or other minerals common in South America. Much valuable timber is found in the forests, and the wooded districts situated upon the rivers possess a ready means of transport. Among the trees are several species of dye-wood, several trees which yield valuable juices, as the India-rubber and its cognate trees; and an especially valuable shrub called the *Maté* (q. v.), or Paraguay tea-tree, which forms one of the chief articles of commerce, being in general use throughout La Plata, Chili, Peru, and other parts of South America. The tree grows wild in the north-eastern districts, and the gathering of its leaves gives employment in the season to a large number of the native population. Many trees also yield valuable gums. Wax and honey are collected in abundance, as is also cochineal, and the medicinal plants are very numerous.

The chief cultivated crops are maize, rice, coffee, indigo, mandioc, tobacco, sugar-cane, and cotton. Nearly three-fourths of the land is national property, consisting partly of the lands formerly held by the Jesuit missions, partly of lands never assigned to individuals, partly of lands confiscated in the course of the revolutionary ordeal through which the country has passed. The national estates have, for the most part, been let out in small tenements, at moderate rents. Under the dictator Francia (1814—1840), agriculture made considerable progress, and the breed of cattle and horses was much improved, and the stock increased. The few manufactures are sugar, rum, cotton, and woollen cloths, and leather. The commerce of the country is chiefly in the hands of the government, which holds a monopoly of the export of P. tea. In 1880, the total value of the exports was £252,000; of imports somewhat less. The chief exports were maté, tobacco, hides, oranges, and bark for tanning; imports, cotton goods, wine, grain, rice, linen, silk, petroleum, &c. Till the war of 1865—1870, P. had no national debt, but its terrible losses compelled it then to contract obligations amounting to upwards of £47,000,000. Three millions were contracted in England on the security of the public lands of P., estimated at upwards of £19,000,000; but payment of interest and sinking fund ceased in 1874, and prior to that was paid directly out of the capital. The military force, which, during the five years' war, was raised to 60,000 men, has now been reduced to 500. The established religion is the Roman Catholic, the ecclesiastical head of which is the Bishop of Asuncion. Education is very widely diffused; and it is said that there are but few of the people who are not able to read and write.

The history of P. is highly interesting. It was discovered by Sebastian Cabot in 1526, but the first colony was settled in 1535 by Pedro de Mendoza, who founded the city of Asuncion, and established P. as a province of the viceroyalty of Peru. The warlike native tribe of the Guaranis, however, a people who possessed a certain degree of civilization, and professed a dualistic religion, long successfully resisted the Spanish arms, and refused to receive either the religion or the social usages of the invaders. In the latter half of the 16th c., the Jesuit missionaries were sent to the aid of the first preachers of Christianity in P.; but for a long time they were almost entirely unsuccessful, the effect of their preaching being in a great degree marred by the profligate and cruel conduct of the Spanish adventurers, who formed the staple of the early colonial population. In the 17th c. the home government consented to place in their hands the entire administration, civil as well as religious, of the province; which, from its not possessing any of the precious metals, was of little value as a source of revenue; and in order to guard the natives against the evil influences of the bad example of European Christians, gave to the Jesuits the right to exclude all other Europeans from the colony. From this time forward the progress of civilization as well as of Christianity was rapid. The legislation, the administration, and the social organization of the settlement were shaped according to the model of a primitive Christian community; or rather of many communities under one administration; and the

accounts which have been preserved of its condition, appear to present a realization of the ideal of a Christian Utopia.

On the expulsion of the Jesuits from P. in 1768, the history of which is involved in much controversy, the province was again made subject to the Spanish viceroys. For a time the fruits of the older civilization maintained themselves; but as the ancient organization fell to the ground, much of the work of so many years was undone; the communities lapsed into disorganization, and by degrees much of the old barbarism returned. In 1776, P. was transferred to the newly-formed viceroyalty of Rio de la Plata; and in 1810 it joined with the other states in declaring its independence of the mother kingdom of Spain, which, owing to its isolated position, it was the earliest of them all to establish completely. In 1814, Dr. Francia (q. v.), originally a lawyer, and the secretary of the first revolutionary junta, was proclaimed dictator for three years; and in 1817, his term of the office was made perpetual. He continued to hold it till his death in 1840, when anarchy ensued for two years; but, in 1842, a national congress elected two nephews of the dictator, Don Alonso and Don Carlos Antonio Lopez, joint consuls of the republic. In 1844, a new constitution was proclaimed, and Don Carlos was elected sole president, with dictatorial power which he exercised till his death in 1862, when he was succeeded by his son, Don Francisco Solano Lopez, whose name has become notorious in connection with the tragic struggle of 1865—1870, in which the Paraguayans made a heroic but unavailing fight against the combined forces of Brazil, the Argentine Confederation, and Uruguay. The war was brought to a close by the defeat and death of Lopez at the battle of Aquidaban, March 1st 1870. In June 1870, a congress voted a new constitution, which was proclaimed on the 25th Nov. It is modelled on that of the Argentine Confederation, the legislative authority being vested in a congress of 2 houses, and the executive in a president, elected for 6 years. P. was till 1876 partially occupied by Brazilian troops, and was virtually a Brazilian province.

The central department, in which the capital, Asuncion, is situated, contains nearly one-third of the whole inhabitants; and the capital itself, 10,000 to 20,000. Asuncion is connected by railway with Paraguari. The inhabitants of the towns consist chiefly of whites, or of half-breeds, speaking Spanish. The native population of the provinces are chiefly Guaranis, speaking the Guaraní language.

PARAGUAY, an important river of South America, an affluent of the Parana (q. v.), rises in the Brazilian province of Matto Grosso, on a plateau of red sandstone, in lat. 18° 30' S., long. about 55° 50' W., 9585 feet above sea-level. The sources of the river are a number of deep lakes, and eight miles from its source the stream already has considerable volume. Pursuing a south-west course, and after flowing through a level country covered with thick forests, the P. is joined from the west by the Jauru, in lat. 16° 30' S. It then continues to flow south through the Marsh of Karayes, which, during the season when the stream rises, is an expansive waste of waters, stretching far on each side of the stream, and extending from north to south over about 200 miles. The river still pursues a circuitous but generally southward course, forming from 20° to 22° S. the boundary-line between Brazil and Bolivia, thence flowing south-south-west through the territories of Paraguay to its junction with the Parana, in lat. 27° 17' S., a few miles above the town of Corrientes. Its chief affluents are the Cuyaba, Tacuary, Mondego, and Apa on the left, and the Jauru, Pilcomayo, and Vermejo on the right. Except in the marshy districts, the country on both banks of the river is rich and fertile, and abounds in excellent timber. The entire length of the river is estimated at 1800 miles; it is on an average about half a mile in width, and is navigable for steamers to the mouth of the Cuyaba, 100 miles above the town of Corumba. The waters of the P., which are quite free from obstructions, were declared open to all nations in 1852; and now Brazilian mail-steamers ply monthly between Monte Video and Cuyaba on the river of the same name, one of the head-waters of the P.; and there are several lines of steamers between Buenos Ayres and Asuncion.

PARAGUAY TEA. See *MATÉ*.

PARAHÍ'BA, one of the most eastern maritime provinces of Brazil, bounded on the N. by Rio Grande do Norte, on the S. by Pernambuco, on the W. by Ceara, and on the E. by the Atlantic. Area, 81,500 sq. m.; pop. (1872) 376,226. It is traversed by a river of the same name, by a number of smaller streams, and by mountainous ridges, between which are valleys, the soils of which are, for the most part, dry and sandy. Cotton of excellent quality, mandioc, and tobacco are grown; and cotton, sugar, and timber are exported. Capital, Parahiba (q. v.).

PARAHIBA, a seaport of Brazil, capital of the province, and situated on the river of the same name, about 10 miles from the sea. Besides the cathedral, it contains a number of religious houses, two colleges, and other educational institutions. The

port is good for small vessels, and the coasting-trade is large. Pop. 15,000.

PARALLAX is the apparent displacement of an object caused by a change of place in the observer. When an object at M is looked at from P , it appears in line with some object, S ; but after the observer has moved to E , M has apparently retrograded to a position in line with S' ; this apparent retrogression is denominated *parallax*. The angle PME is called the 'angle of parallax,' or the 'parallactic angle,' and is the measure of the amount of

Fig. 1.

parallax. To astronomers, the determination of the parallax of the heavenly bodies is of the utmost importance, for two reasons—first, from the necessity of referring all observations to the earth's center, i. e., so modifying them as to make it appear as if they had been actually made at the earth's center; and secondly, because parallax is our only means of determining the magnitude and distance of the heavenly bodies. The *geocentric* or *daily* parallax—as the apparent displacement of a heavenly body, due to its being observed from a point on the surface of the earth instead of from its center, is called—is determined as follows: Let P and P' be two stations on the surface of the earth (fig. 2), E its center, M the

Fig. 2.

object to be observed, and Z and Z' the zeniths respectively of the observers at P and P' (points which, if possible, should be on the same meridian exactly); then at P and P' let the *zenith distances*, ZPM and $Z'P'M$, be observed simultaneously, and since the latitudes of P and P' are known, and consequently their difference of latitude, or the angle PEP' , is known, from these three the angle PMP' (the sum of the parallaxes at P and P') is at once found; and then, by a trigonometrical process, the separate angles or parallaxes PME and $P'ME$.

When the parallax of M , as observed from P , is known, its distance from E , the center of the earth, can be at once found. When the heavenly body is on the horizon, as at O , its parallax is at a maximum, and is known as the *horizontal* parallax. The geocentric parallax is of use only in determining the distances of those heavenly bodies at which the earth's radius subtends a considerable angle; and as the moon and Mars (when in opposition) are the only such bodies, the parallax of the other celestial bodies must be determined in a different manner. The parallax of the Sun (q. v.) is found by observation of the *transit* of Venus across his disk, a much more accurate method than that above described. The parallaxes of the other planets are easily determined from that of Mars.

In the case of the fixed stars, at which the earth's radius subtends an infinitesimal angle, it becomes necessary to make use of a much larger base-line than the earth's radius, and as the largest we can employ is the radius of the earth's orbit, it accordingly is made use of, and the displacement of a star, when observed from a point in the earth's orbit instead of from its center, the sun, is called the *annual* or *heliocentric* parallax. Here the base-line instead as in the former case, of being 4000 miles, is about 92,000,000 miles, and the two observations necessary to determine the parallactic angle are made from two points on opposite sides of the earth's orbit, at an interval as nearly as possible of half a year. Yet, notwithstanding the enormous length of the base-line, it bears so small a proportion to the distances of the stars, that only in three or four cases have they been found to exhibit any parallactic motion whatever, and in no case does the angle of parallax amount to $1''$ (see STARS). The geocentric horizontal parallax of the moon is about $57' 4''$; that of the sun, about $8''$; and of the double star, 61 *Cygni*, the heliocentric parallax has been determined by Bessel to be $348''$, equivalent to about 15 millionths of a second of geocentric horizontal parallax. Parallax affects every observation of angular measurement in the heavens, and all observations must be corrected for parallax, or, in astronomical phrase, referred to the earth's center before they can be made use

of in calculation. The position of a body, when noted from the surface of the earth, is called its *apparent* position; and when referred to the center, its *real* position.

PARALLEL FORCES are those forces which act upon a body in directions parallel to each other. Every body, being an assemblage of separate particles, each of which is acted on by gravity, may thus be considered as impressed upon by a system of parallel forces. The following demonstration will exhibit the mode in which the amount and position of the resultant force are found: Let P and Q be two parallel forces acting at the points A and B respectively, either in the same (fig. 1) or in opposite (fig. 2) directions; join AB , and in this line, at the points A and B ,

Fig. 1.

Fig. 2.

apply the equal and opposite forces S and S , which counterbalance each other, and therefore do not affect the system. Find M and N (see COMPOSITION and RESOLUTION OF FORCES), the resultants of P and S , and Q and S respectively, and produce their directions till they meet in D , at which point let the resultants be resolved parallel to their original directions; then there are two equal forces, S and S , acting parallel to AB , but in opposite directions, and thus, as they counterbalance each other, they may be removed. There then remain two forces, P and Q , acting at D , in the line DC , parallel to their original directions, and their sum (fig. 1) or difference (fig. 2), represented by R , is accordingly the resultant of the original forces at A and B . To find the position of C , the point in AB , or AB produced, through which the resultant passes, it is necessary to make use of the well-known property denominated the *Triangle of Forces* (q. v.), according to which three forces S , M , and P are proportional to the lengths of AC , AD , DC , the sides of the triangle ADC ; then $S : P :: AC : CD$, similarly $Q : S :: DC : CB$, therefore $Q : P :: AC : BC$, and $Q \perp P$ or $R : P :: AC \perp BC$ or $AB : BC$, from which proportions we derive the principle of the lever, $P \times AC = Q \times BC$, and also that $R \times BC = P \times AB$, whence $BC = \frac{P}{R} \times AB$, and the point C is found. The failing case of this proposition is when P and Q acting in opposite parallel directions at different points are equal, in which case the resultant $R = Q - P = Q - Q = 0$.

In all other cases there is a progressive motion, such as would be caused by the action of a single force $R (= Q \perp P)$ acting at the point C in the direction CR ; but in the failing case, since $R = 0$, there is no progressive motion, but a rotatory movement round the center of AB . See COUPLE. It is of no consequence whether

Fig. 3.

A and B be the true points of application of the forces P and Q , provided their directions when produced pass through these points, and the point of application of the resultant need not be in the line joining the points of application of the component forces, but its direction must when produced pass through C . If there be more than two parallel forces, the resultant of the whole is found by compounding the resultant of the first two with the third in the way given above, thus obtaining a new resultant, which is similarly combined with the fourth force; and so on till the final resultant is found. The center of gravity is only a special name for the point of application of the final resultant of a number of parallel forces.

PARALLELEPIPED (Gr.), frequently, but improperly written *Parallelepiped*, is a solid figure having six faces, the faces being invariably parallelograms, and any two opposite faces equal, similar, and parallel. If the faces are all squares, and consequently equal, the parallelepiped becomes a cube. The volume of a parallelepiped is found by multiplying the area of one face by its distance from the opposite one.

PARALLELOGRAM, in Mathematics, is a quadrilateral rectilineal figure which has its opposite sides parallel; the opposite sides are therefore equal, and so are the opposite angles. If one angle of a parallelogram be a right angle, all its angles are right angles, and the figure is then called a *rectangular parallelogram*, or, shortly, a *rectangle*; and if at the same time all the sides are equal, the figure is a *square*, otherwise it is an *oblong*. If the angles are not right angles, but all the sides are equal, it is called a *rhombus*; and if the opposite sides only are equal, a *rhomboid*. The two lines which connect the opposite corners of a parallelogram are called its *diagonals*, each bisects the parallelogram, and they bisect each other; the sum of their squares also is equal to the sum of the squares of the sides of the parallelogram.

All parallelograms which have equal bases and equal altitudes are equal in area, whether they be similar in shape or not, and the area of a parallelogram is found by multiplying its base by the height.

PARALLELOGRAM OF FORCES. See COMPOSITION OF FORCES.

PARALLELS, in Military language, are trenches cut in the ground before a fortress, roughly parallel to its defences, for the purpose of giving cover to the besiegers from the guns of the place. The parallels are usually three, with zigzag trenches leading from one to another. The old rule used to be to dig the first at 600 yards distance, but the improvements in artillery have rendered a greater distance necessary; and at Sebastopol, the allies made their first trench 2000 yards from the walls. The third trench is very near to the besieged works, and from it saps and zigzag approaches are directed to the covertway.—The bearing of parallels in the general conduct of a SIEGE will be found described under that head.

PARALLELS or CIRCLES OF LATITUDE are circles drawn round the surface of the earth parallel to the equator. They may be supposed to be the intersections with the earth's surface of planes which cut the earth at right angles to its axis. The greatest of these circles is the equator, which has the center of the earth for its center, the radius for its radius, and is equally distant at all points from each pole. It is evident that of the others, those next the equator are greater than those more remote, and that they become less and less till at the poles they vanish altogether. The radius of any one circle is evidently equal to the earth's radius multiplied into the cosine of its latitude or distance from the equator. The rotary velocity of the earth's surface, which is about 17½ miles per minute at the equator, is only 8½ miles in lat. 60°, in lat. 82½° (the most northerly point yet reached) is only 2½ miles; and in lat. 89½° (within 35 miles of the pole) is not more than 267 yards per minute.

The most important parallels of latitude are the *Tropics of Cancer* (23° 28' N. lat.) and *Capricorn* (23° 28' S. lat.), and the *Arctic* (66° 32' N. lat.) and *Antarctic Circles* (66° 32' S. lat.).

PARALYSIS (Gr., a loosening or relaxing), or **PALSY**, is a loss, more or less complete, of the power of motion; but by some writers the term is employed to express also loss of sensation. When the upper and lower extremities on both sides, and more or less of the trunk, are involved, the affection is termed *General Paralysis*. Very frequently only one-half of the body laterally is affected, the other side remaining sound; to this condition the term *Hemiplegia* is given. When the palsy is confined to all parts below an imaginary transverse line drawn through the body, or to the two lower extremities, the condition is termed *Paraplegia*. When one part of the body, as a limb, one side of the face, &c., is exclusively attacked, the affection is known as *local palsy*. In some cases the loss of sensation and the power of motion in the paralyzed part is entire, while in others it is not so. In the former the paralysis is said to be *complete*, in the latter, *partial*.

In most cases, but not invariably, sensibility and motion are simultaneously lost or impaired. When motion is lost, but sensation remains unimpaired, the affection has received the name of *akinesia* (Gr. *a*, not, and *kinesis*, motion). More rarely, there is a loss of sensibility while the power of motion is retained; and to such cases the term *anesthesia* (Gr. *a*, not, and *aisthesis*, sensation) is applied. This affection occurs most frequently in the organs of sense; and in the tongue, for example, in which the sense of taste may be lost, without any defect of movement.

Paralysis is in most cases a mere symptom of disease existing in some other part than that apparently affected; as, for example, in the brain or spinal cord, or in the conducting nerves between either of these organs and the palsied organ. Sometimes, how-

ever, it is a purely local affection, depending upon a morbid condition of the terminal extremities of the nerves. The varieties in the condition of the brain and spinal cord which occasion paralysis are somewhat numerous; as, for example, congestion, hemorrhagic and serous effusion, softening, fatty degeneration, fibrinous exudation, suppuration, hydatids, various morbid growths, depressed bone from external violence, &c. It is highly probable, also, that palsy may sometimes result from mere functional disorder of the nervous centers—a view which is confirmed by the fact that a *post mortem* examination of a patient who has suffered from this affection sometimes fails to detect any apparent lesion. Paralysis may originate in a nervous trunk, if it is compressed by a tumor, or otherwise mechanically affected, or if it is the seat of morbid action tending in any way to disorganize it; or it may be due to an abnormal condition of the terminations of the nerves, which may be rendered unfit for receiving impressions either from the external world or from the brain by prolonged disuse, by continuous or severe pressure, by exposure to cold, by disorganization of their own tissue, or by the depressing action of various metallic poisons, especially lead.

We shall briefly notice the symptoms and causes of the most important forms of paralysis, before offering any remarks on the general principles of treatment. *Hemiplegia* (Gr. *hemi*, half, *plegma*, I strike) affects one lateral half of the body, and is that form of palsy to which the term *paralytic stroke* is commonly applied. The parts generally affected are the upper and lower extremities, the muscles of mastication, and the muscles of the tongue on one side. In a well-marked case the patient when seized falls to the ground, all power of motion in the affected arm and leg being lost. The palsy of the face which accompanies hemiplegia is usually quite distinct from the affection known as *facial palsy*, which is an affection of the facial nerve or *portio dura*. See NERVOUS SYSTEM. It is the motor branches of the fifth or trifacial nerve going to the muscles of mastication which are generally involved in hemiplegia, and consequently the cheek is flaccid and hangs down, and the angle of the mouth is depressed on the affected side. The tongue when protruded points towards the paralyzed side, and there is often imperfect articulation, in consequence of the lesion commonly affecting the hypoglossal nerve. Hemiplegia may arise from lesions of various kinds, as, for example, (1) from hemorrhage, or some other morbid change in the brain, in which case the palsy is on the side of the body opposite to the lesion, in consequence of the decussation or crossing over of nervous fibres from one side to the other that occurs at the upper part of the Spinal Cord (q. v.); (2) from spinal disease below the point of decussation just noticed; in this case the palsy, and the lesion causing it, are on the same side of the body. It is also sometimes associated with hysteria, epilepsy, and chorea, but in these cases it usually disappears in a few hours.

Paraplegia (Gr.) is usually confined to the two lower extremities, but the muscles of the lower part of the trunk and of the bladder and rectum are sometimes affected. There are at least two distinct forms of paraplegia, viz. (1) Paraplegia dependent on primary disease of the spinal cord or its membranes, and especially on Myelitis (q. v.); and (2) Reflex Paraplegia, i. e., paraplegia consequent on disease of the kidneys, bladder, urethra, prostate womb, &c. These two forms of paraplegia differ in many of their phenomena, and the most important of these points of difference have been arranged in a tabular form by Dr. Brown Sequard, in his *Lectures on Paralysis of the Lower Extremities*, to which we must refer for the best information on this form of palsy. Paraplegia usually comes on slowly, with a gradual increase of its symptoms. The reflex form is, of course, by far the most favorable, as it usually abates spontaneously on the subsidence of the primary disease.

Facial Palsy, although locally affecting only a small part of the body, is a disorder of sufficient importance to require a definite notice. In this affection there is a more or less perfect loss of power over all the muscles supplied by the *portio dura*, or facial nerve. The following graphic account of the appearance of the patient is condensed from Dr. Watson's *Lectures on the Practice of Physic*. From one-half of the countenance all power of expression is gone; the features are blank, still, and unmeaning; the eyelids apart and motionless. The other half retains its natural cast, except that, in some cases, the angle of the mouth on that side seems drawn a little awry, in consequence of the want of counterpoise from the corresponding muscular fibres of the palsied side. The patient cannot laugh, or weep, or frown, or express any feeling or emotion with one side of his face, while the features of the other may be in full play, nor can he spit or whistle properly. One-half of the aspect, with its unwinking eye, its fixed and solemn stare, might be that of a dead person; the other half is alive and merry.

To those who do not comprehend the possible extent of the misfortune, the whimsical appearance of the patient is a matter of mirth and laughter; while on the other hand, his friends imagine that he has had a stroke, and that he is in a very dan-

gerous state. The nerve may be unable to discharge its duties in consequence of disease within the cavity of the skull, and in that case there is very serious danger; but in the great majority of cases the nervous function is interrupted in that part of the *portio dura* which lies encased in the temporal bone, or in the more exposed part which issues in front of the ear; and hence this form of palsy is generally unattended with any danger to life. It may arise from various causes. Sometimes it is the consequence of mechanical violence, sometimes of tumors pressing on it in the region of the parotid gland, and it very frequently arises from the mere exposure of the side of the face for some time to a stream of cold air.

It yet remains to notice certain kinds of paralysis which differ either in their characters, or in their causes, from those which have been already described—viz., *Shaking Palsy*, or *Paralysis Agitans*; and the palsies induced by various poisons. *Shaking Palsy* has been defined as 'involuntary tremulous motion, with lessened muscular power in parts not in action, and even when supported; with a propensity to bend the trunk forwards, and to pass from a walking to a running pace; the senses and intellect being uninjured.' It is chiefly an affection of old age, and often goes no further than to cause an unceasing nodding and wagging of the head in all directions. Somewhat analogous to this form of palsy is that peculiar kind of trembling which is often noticed in persons who are much exposed to the vapor of mercury; *Mercurial Tremor*, as it is termed by the physicians, and *The Trembles*, as the patient usually calls it. It consists in a convulsive agitation of the voluntary muscles, especially when an attempt is made to cause them to act under the influence of the will; a patient with this affection walks with uncertain steps, his limbs trembling and dancing as if they had been hung upon wires.

When sitting down he exhibits little or no indication of his disease, but on rising he cannot hold his legs steady, nor direct them with precision; and in severe cases he falls to the ground if not supported. The arms are similarly agitated, and the tongue is usually so tremulous as to render the articulation hurried and unnatural. The disease is especially common in artisans employed in the gilding of metals, and particularly of silver, by means of heat; it is also frequent among the workers of quicksilver mines, in which the crude metal is purified by heat. The time required for the production of the disease varies extremely in different cases (according to Dr. Watson, from two years to five-and-twenty). The duration of the complaint is considerable; it may last two or three months, or longer, but it is seldom fatal.

The palsy arising from the absorption of lead has been already noticed in the article LEAD-POISONING.

A specific form of paralysis of the lower extremities, consequent on the use of flower from the beans of the *Lathyrus sativus*, is common in certain parts of India and in Tibet. The ripe bean is an ordinary article of food when made into flour, but it is generally used with wheat or barley flour; it is only when it exceeds one-twelfth part that it is at all injurious, and when it exceeds one-third that the paralysis sets in. Other species of *Lathyrus* have been known occasionally to induce similar symptoms in European countries.

We shall enter into no details regarding the treatment of hemiplegia and paraplegia, as the management of these serious affections should be exclusively restricted to the physician. When a patient has an attack of hemiplegia (or a *paralytic stroke*) all that should be done before the physician arrives is to place him in a horizontal position, with the head slightly raised, and to remove any impediments presented by the dress to the free circulation of the blood. Should the physician not arrive in an hour or two, it may be expedient to give the patient a sharp purge (half a scruple of calomel, followed in a few hours by a black draught, if he can swallow; and two drops of croton oil, mixed with a little melted butter, and placed on the back of his tongue, if the power of deglutition is lost), and without waiting for its action, to administer an injection (or clyster) consisting of half an ounce of oil of turpentine suspended (by rubbing it with the yoke of an egg) in half a pint of thin gruel; and cold lotions may be applied to the head, especially if its surface be hot. The question of blood-letting—the universal treatment a quarter of a century ago—must be left solely to the physician. It should, however, be generally known, that if the patient be cold and collapsed; if the heart's action be feeble and intermittent, if there be an anæmic state; if the patient be of advanced age; if there is evidence of extensive disease of the heart or arterial system; or lastly, if there is reason, from the symptoms, to believe that a large amount of hemorrhage has already taken place in the brain; these singly, and *a fortiori* conjointly, are reasons why blood should not be abstracted.

Facial palsy, unless the seat of the disease be within the cavity of the cranium, will usually yield in the course of a few weeks to cupping, and blistering behind the ear of the affected side, purgatives, and small doses of corrosive sublimate (one-twelfth of a grain three times a day, combined with a little of the compound

tincture of bark), which must be stopped as soon as the gums are at all affected. Exposure to cold air must be carefully avoided during treatment.

Little or nothing can be done to cure *Paralysis Agitans*. In the treatment of *Mercurial Tremor*, the first step is to remove the patient from the further operation of the poison, while the second is to remove the poison already absorbed into the system, which is effected by the administration of iodide of potassium. This salt combines with the metallic poison in the system, and forms a soluble salt (a double iodide of mercury and potassium), which is eliminated through the kidneys. Good food and tonics (steel or quinia, or the two combined) should be at the same time freely given.

The writer of this article has no personal knowledge of the treatment that should be recommended in the paralysis produced by the use of *Lathyrus sativus*, but cases are reported which seem to have been benefited by good diet, tonics, strychnia, and the application of blisters to the loins.

PARAMAGNETISM, as opposed to Diamagnetism. See DIAMAGNETISM.

PARAMARIBO, the capital of Dutch Guiana, is situated on the western bank of the river Surinam, about 10 miles from its mouth, in 5° 45' N. lat., and 55° 15' W. long. It forms a rectangle of nearly a mile and a half in length by three-quarters in breadth. The streets are broad, covered with shell-sand, and planted on both sides with orange, lemon, tamarind, and other trees. Near the river, the houses, which are chiefly of wood, stand somewhat closely together, but in the remoter parts each is surrounded by its own garden. The rooms are wainscoted with the choicest woods, and elegantly furnished.

In approaching P. from the sea, Fort Zeelandia is first reached; then the Bureau of Finance and Court of Justice on the Government Plain, which is surrounded by stately cabbage-palms; the governor's house, with shady double avenue of tamarind-trees; and lastly, the business streets stretching along the river side. There are a Dutch Reformed, a Lutheran, Moravian, two Roman Catholic churches, and two synagogues. Fort Zeelandia has a large and beautiful barrack, with several roomy houses for the officers. P. has a neat, pleasant, and picturesque appearance, the white painted houses, with bright-green doors and windows, peeping out from the shady trees, and the river being thronged with the tent-boats and canoes which are constantly arriving and departing.

On 1st January 1875, the population amounted to 21,755. By royal decree of 6th February 1851, the flogging of slaves in the Netherlands West Indies was forbidden, except through officers appointed for the purpose, and the number of lashes was limited. This check, however, was frequently evaded, and the greatest barbarities practised, so that the feeling in favor of emancipation increased in the Netherlands, and a bill was passed, 8th August 1862, for emancipating the slaves on the 1st July 1863.

P. is the only port, except Nickerie Point, at the mouth of the Corentyne. In 1870—1880, the number of ships entering the ports of Dutch Guiana varied from 190 to 230 a year, and the tonnage from 20,000 to 25,000 tons. By far the largest number were British. About a fourth part cleared at Nickerie, a very productive portion of the colony, in which sugar, molasses, and rum are manufactured in large quantities.

The climate of D. Guiana is not healthy. From this and other causes the deaths annually exceed the births. Elephantiasis Arabum and Lepa are fearfully prevalent among the black population of P. and neighborhood. The rainfall (67 inches) varies much, being smallest at Nickerie, in the west, and largest at Montyou in the east of the colony (128 inches). In Georgetown, British Guiana, the average fall is 100.50 inches.

As to religion, about 40,000 of the inhabitants of the colony are reckoned Christians, of whom 22,000 are Moravians (mostly converts by missionary agency), 5000 Dutch Reformed (mainly in Paramaribo), 13,000 Catholics. There are about 700 Jews. The Moravian missionaries have missions in the interior, especially amongst the bush-negroes, who speak a language based on broken English, with Dutch, Portuguese, and Indian additions. The colony possesses 60 schools and 5000 pupils, of whom 1300 are in the capital. The great proportion of the births in the colony are illegitimate. The influx of immigrants in 1870-80 varied from 2720 in 1873 to 43 in 1876. The immigrants are mostly from British India.

The coast of Dutch Guiana is an alluvial deposit formed by the rivers and equatorial stream which flows eastwards. Further inland, the soil is diluvial loam, bearing the finest timber trees; and south of this line are extensive savannahs of white sand, stretching towards the hills and mountains of the interior, which are chiefly of gneiss and granite.

The Bank of Surinam, which is the only one in the colony, has its headquarters at P. It has a capital of \$400,000.

PARAMA'TTA is a light worsted twilled fabric for female dress. It was invented at Bradford, in Yorkshire, and has become an important manufacture of that place. The web consists of combed merino wool, and the warp of cotton. It resembles in texture the Coburg and Orleans cloths.

PARAMATTA, a pleasantly situated town of New South Wales, stands near the west extremity of Port Jackson, on a small river of the same name, and is 15 miles by land west-north-west of Sydney, with which it is connected both by steamer and railway. The houses are mostly detached, and the streets are wide and regular, the principal one being about a mile in length. The institutions comprise churches, schools, an orphan and a lunatic asylum, and a prison. There was formerly an observatory here; but it was removed to Sydney in 1858. 'Colonial tweeds,' 'Paramatta cloths' (first made from wool exported hence) and salt are manufactured. Pop. (1871) 6103; (1881) 8433.

The town of P., formerly called Roselhill, is, after Sydney, the oldest in the colony. It is now always spelt *Parramatta* by Australian authorities.

PARAMETER, or **LATUS RECTUM**, a term used in conic sections, denotes in the case of the parabola, a third proportional to the abscissa of any diameter and its corresponding ordinate; in the ellipse and hyperbola, a third proportional to a diameter and its conjugate. The parameter of any diameter is, in the case of the parabola, the same as the double ordinate of that diameter which passes through the focus, and is four times as long as the distance between the diameter's vertex and the directrix. The term parameter was also at one time used to denote *any* straight line about a curve, upon which its form could be made to depend, or any constant in its equation, the value of which determined the individual curve; but its employment in this sense is now discontinued, except in the theory of homogeneous differential equations, where the constants for the purpose of aiding the solution, are supposed to vary; and the method is consequently denominated the 'Variation of the Parameters.' In the application of this method to determine the orbital motions of the planets, the 'seven necessary data' (see **ORBIT**) were called parameters, but for this the term 'elements' is now substituted.

PARANA', a province in the south of Brazil, is bounded on the N. by the province of Sao Paula, on the E. by the Atlantic, S.E. by Santa Catharina, S. by Rio Grande do Sul, W. by Paraguay and Matto Grosso. Area stated at 72,000 sq. m. Pop. (1872) 126,722, one sixth of whom are slaves. The capital is Curitiba, and previously to 1852 this province formed a territory called the Comarca of Curitiba, included in the province of Sao Paulo. It fully commenced its provincial career in 1853. The sea coast is indented by several bays, but the chief and almost the only portas yet is Paranagua. A line of mountains run parallel to the coast at a distance of about 80 miles inland, and throws out spurs and branches westward. The streams flowing east from this water-shed, though numerous, are inconsiderable; while the rivers flowing westward, into the Parana (q. v.), which forms the western boundary of the province, are all about or upwards of 400 miles in length. The principal are the Paranapanema, Ivay, Piquery, and Yguassu. The climate is unusually healthy; the soil is fertile; and agriculture, rearing cattle and swine, and gathering *mâté* or Paraguay tea are the chief employments. The capital, Curitiba, has manufactures of coarse woollens, and with its agricultural surroundings has a pop. of 12,000.—The chief port, Paranagua, on a bay of the same name, is about 400 miles south-west of Rio de Janeiro. It contains about 3000 inhabitants, and exports *mâté* to the value of 1,000,000 dollars annually.

PARANA, an important river of Brazil, rises in the province of Minas Geraes, about 100 miles north-west of Rio de Janeiro. It flows west for upwards of 500 miles, through the provinces of Minas, Geraes and São Paulo. In the latter it is joined by the Parnahiba, after which its course alters, and it flows south-south-west to Candelaria. Passing this town, it flows west for 200 miles to its confluence with the Paraguay (q. v.), and then bending southward, passes Santa Fe, below which its channel frequently divides and encloses numerous islands. After passing Santa Fe, it rolls onward in a south-east direction, and unites with the Uruguay in forming the Rio de la Plata. Entire length about 2400 miles. It draws a number of considerable tributaries from the province of Parana (q. v.); and of the others, the chief are the Paraguay, Uruguay, Pardo, Tiete, and Parnahiba. For vessels drawing 16 feet it is navigable to Corrientes, upwards of 600 miles from its mouth.

PARAPET (Ital. *para-petto*, from *parare*, to protect, and *petto*, the breast), a wall raised higher than the gutter of a roof for protection; in military works, for defence against missiles from without (see **FORTIFICATION**); in domestic buildings, churches, &c., to prevent accident by falling from the roof. Parapets are of very ancient date. The Israelites were commanded to build 'a battlement' round their flat roofs. In classic architecture, balus-

trades were used as parapets. In Gothic architecture, parapets of all kinds are used. In early work they are generally plain, but in later buildings they are pierced and ornamented with tracery, which

Ornamented Gothic Parapet.

is frequently of elaborate design, especially in French Flamboyant work. Shields and little arcades are also used as ornaments to parapets; and the battlements of castles are imitated in the parapets of religious and domestic buildings.

PARAPHRASE (Gr. *para*, beside, and *phrazein*, to touch), an addition to the signature formed by a flourish of the pen, which, during the middle ages, constituted some sort of provision against forgery. Its use is not altogether extinct in diplomacy, and in Spain the paraph is still a usual part of a signature.

PARAPHERNALIA (Gr. *para*, beside, or beyond; *pherne*, dower), is a term borrowed from the Roman law to denote certain articles of personal adornment and apparel belonging to a married woman. According to the usual rule in the law of England, all the personal property of a woman becomes the property of her husband when the marriage takes place, unless there is a marriage settlement; but there is an exception as regards the trinkets and dress of the wife so far as suitable to her rank in life, and which she continues to use during the marriage. In such a case the property in these articles does not vest absolutely in the husband. He cannot bequeath them by his will to a third person, but if he gave them to the wife, he may pawn, or sell, or give them away, and they can be seized in execution to pay his debts, except so far as they constitute necessary clothing. And if he were to die insolvent, they may, except that part which is necessary clothing, be taken by the husband's creditors. If the paraphernalia were given, not by the husband but by a third party before or during marriage, then they are presumed to be given for the wife's separate use, and the husband or his creditors cannot in any way interfere with them. In the law of Scotland, the paraphernalia of a married woman include not merely personal clothing and trinkets, but articles of furniture, such as a chest of drawers. The husband there can neither pawn, nor pledge, nor give away the paraphernalia, nor can his creditors attach them either during his life or after his death.

PARAPHRASE (Gr. *para*, beside, and *phrazein*, to speak) is the name given to a verbal expansion of the meaning either of a whole book, or of a separate passage in it. A paraphrase consequently differs from Metaphrase, or strictly literal translation, in this, that it aims to make the sense of the text clearer by a lucid circumlocution, without actually passing into commentary. The versified passages of Scripture, forming part of the Psalmody of the Scottish Church, are popularly known as 'the Paraphrases.'

PARAPLEGIA. See **PARALYSIS**.

PARAS'ARA is the name of several celebrated personages of ancient India, met with in the *Mahābhārata* (q. v.), the *Purān'as* (q. v.), and other works. Of one personage of this name, the *Mahābhārata* relates that he was the son of S'akti, who was the son of the patriarch Vasisht'ha. King Kalmāshapāda once meeting with S'akti in a narrow path in a thicket, desired him to stand out of the way. The sage refused; on which the Rāja beat him with his whip, and S'akti cursed him to become a Rākshasa, or demon. The Rāja, in this transformation, killed and ate S'akti, together with the other sons of Vasisht'ha. S'akti, however, had left his wife, Adris'yanti, pregnant, and she gave birth to Parās'ara, who was brought up by his grandfather. When he grew up, and was informed of his father's death, he instituted a sacrifice for the destruction of all the Rākshasas, but was dissuaded from its completion by Vasisht'ha and other sages. The same legend is referred to by the *Vishn'u-Purān'a*, where P. is introduced as relating, himself, part of this story, and adding, that the saint Pulastya, one of the mind-born sons of Brahmi, in reward of the clemency he had shown even towards such beings as the Rākshasas, bestowed on him the boon of becoming the author of a compendium, or rather the compiler, of the *Purān'as*, and of the *Vishn'u-Purān'a* in particular. 'This tradition,' Professor Wilson observes (*Vishn'u-Purān'a*, ed. Hall, vol. i. p. 10), 'is incompatible with the general attribution of all the *Purān'as* to Vyāsa; but it may perhaps point to a later recension when, to the native mind, Vyāsa would still remain the reputed author of the older *Purān'as*, although, of course, even this assumption has little claim to historical truth.'

A P., probably different from the one named, is the author of a

celebrated code of laws; he is mentioned by Yājñavalkya in his standard work, and often quoted by the commentaries.—A probably third P. is the reputed author of a Tantra (q. v.); and a fourth, the author of an astronomical work.—Parāś'aras (in the plural) designates the whole family to which the different Parāś'aras belong.

PARASIT'Ā, or ANOPLU'RA, an order of insects, to all of which the name Louse is popularly given. All live as parasites on quadrupeds and birds. The characters of the order are noticed in the article LOUSE. It remains, however, to be added that the order is divided into two sections; in the first of which, *Pediculidea*, the mouth is small and quite suctorial; whilst in the second, *Nirmidea*, it is furnished with mandibles and hooked maxillæ. The species of the first section are found only on man and mammals; those of the second section, almost exclusively on birds, although one infests the dog. The *Nirmidea* show much greater activity than the *Pediculidea*. When a bird dies, the bird-lice congregate near the beak, and seem disquieted, apparently anxious to change their abode.

PARASITE (Gr. from *para*, beside; *sitos*, food; one who eats with another; hence one who eats at the expense of another), a common character in the Greek comedies; a low fellow, who is ready to submit to any indignity, that he may be permitted to partake of a banquet, and who lives as much as possible at the expense of others.

PARASITIC ANIMALS are numerous. Some of them are Entozoa, and some are Epizoa. See these heads. They belong to different classes, and even to different divisions of the animal kingdom; all, however, are invertebrate. Many are of the division *Archiolata*, and many of the division *Radiata*. Besides worms of various kinds, there are among parasites not a few crustaceans, as the Lernæans, &c., and not a few insects, as the Louse. These insects constitute the order *Parasita* or *Anoplura*. Some of the cirrhopods which live in the skin of large marine animals, as whales, can scarcely be regarded as parasitic animals, but rather bear to them a relation such as *Epiphytes* do to parasitical plants, not deriving their food from the animal on which they live. Tape-worms, ascariæ, and other intestinal worms, do not directly draw sustenance from the animal in which they live, by extracting its juices, but they live at its expense, by consuming its food, after the food has undergone, in great part, the process of digestion.

PARASITIC DISEASES constitute one of the recognized orders of disease in Dr. Farr's classification. See NOSOLOGY. In these diseases, certain morbid conditions are induced by the presence of animals or vegetables which have found a place of subsistence within some tissue or organ, or upon some surface of the body of man or of other animals. Even plants are not exempt from disorders of this nature (see PARASITIC PLANTS). The forms of animal life giving rise to parasitic diseases are described in articles ASCARIDES, CESTOID-WORMS, ENTOMIA, EPIZOA, GUINEA-WORM, ITCH-INSECT, LOUSE, NEMATHELMIA, STRONGYLUS, TAPEWORMS, TRICHINA, &c. With the vegetable structures which give rise to special diseases we are less accurately acquainted, in consequence of the limited knowledge of cryptogamic botany possessed by many writers who have recorded their experience of these cases. These parasites are either *fungi* or *algæ*, and are composed of simple sporules, germs, or cells, or of cells arranged in rows or groups, which are so minute as to require the microscope for their recognition. Fungi are the most numerous of all plants in regard to genera and species, and their growth is associated with serious injury both to animal and vegetable life. It is not, however, always easy to determine whether they are the direct cause of disease, or whether the diseased tissue has merely afforded a suitable nidus for their development. 'It is certain,' says Dr. Aitken, who has entered more fully into this subject than any other English writer on the practice of medicine, 'that wherever the normal chemical processes of nutrition are impaired, and the incessant changes between solids and fluids slacken, then, if the part can furnish a proper soil, the cryptogamic parasites will appear. The soil they select is, for the most part, composed of epithelium or cuticle, acid mucus or exudation. Acidity, however, though favorable to their growth, is not indispensable, since some of the vegetable parasites grow upon alkaline or neutral ground, as on ulcerations of the trachea, or in fluid in the ventricles of the brain.

'Certain atmospheric conditions seem favorable to the occurrence of these vegetable parasites. For example, *Tinea tonsurans* may be quite absent for years in places such as workhouses, where it commonly exists, and then for several months every second or third child in the place gets the disease.'

There is undoubted evidence from the observations and experiments of Devergie, Von Bärensprung, and others, that these parasitic diseases may be transmitted by contagion from horses, oxen, and other animals to man; while conversely, Dr. Fox mentions an instance of a white cat which contracted the mange from *Tinea*

tonsurans (ringworm of the scalp), which affected the children of the family to which it belonged—the fungus of the mange in the cat being the same fungus as that of *Tinea* in the human subject, viz., the *Tricophyton* (Gr. *tric* (tric-), of a hair, and *phyton*, a plant).

The principal vegetable parasites associated in man with special morbid states are arranged by Aitken (*The Science and Practice of Medicine*, 1868, 2d edit. vol. ii. p. 177) as follows: 1. *Tricophyton tonsurans*, which is present in the three varieties of *Tinea tonsdens*—viz., *T. circinatus* (ringworm of the body), *T. tonsurans* (ringworm of the scalp), and *T. sycosis menti* (ringworm of the beard). 2. The *Tricophyton sporuloides*, which, together with the above, is present in the disease known as *Plica Polonica*. 3. The *Achorion Schönleini* and *Puccinia favi*, which are present in *T. favosa*, known also as *Favus* (q. v.), and *Porrigio scutulata* (the honeycomb ringworm). 4. The *Microsporon Mentagrophyta*, which is present in *Mentagra*. 5. The *Microsporon furfur*, which occurs in *Pityriasis versicolor*. 6. The *Microsporon Audouini*, which is present in *Porrigio decolans*. 7. The *Mycetoma* or *Chionophye Carteri*, which gives rise to the disease known as the 'fungus foot of India,' &c. 8. The *Oidium albicans* of diphtheria and aphthæ. 9. The *Cryptococcus Cerevisia*, or Yeast Plant, occurring in the urine and contents of the stomach, if there is saccharine fermentation. 10. The *Sarcina Goodserii*, or *Merisipadia ventriculi* (of Robin), found in vomited matters and in the urine. There are strong grounds, based partly on botanical and partly on clinical observation, for believing that the various fungi already described are mere varieties of two or more species in various phases of development.

We shall conclude this article with a brief notice of the most dangerous of all the parasitic diseases—the *Fungus Foot* or *Fungous Disease of India*. It occurs in many parts of India, and the north-east shores of the Persian Gulf. It is a disease which occurs among natives only, so far as has been yet observed, and is undoubtedly due to the presence of a fungus which eats its way into the bones of the foot and the lower ends of the tibia and fibula, penetrating by numerous fistulous canals through the tissue of the entire foot, and tending to cause death by exhaustion, unless amputation is performed in due time. Dr. Carter has described three forms of this disease, in which both the symptoms and the fungoid material differ considerably from each other. A few remarks on the first of these forms will suffice as an illustration of parasitic disease. In this form, the bones of the foot and the lower ends of the leg-bones are perforated in every direction with roundish cavities, varying in size from that of a pea to that of a pistol-bullet, the cavities being filled with the fungoid matter. The surrounding muscles, and subsequently the tendinous and fatty structures, are converted into a gelatiniform mass, in consequence of which the foot presents a peculiar turgid appearance. The structure of the globular fungoid masses is shown in the accompanying figure, which was drawn by Dr. H. J. Carter from a

specimen which he examined immediately after amputation. Examined under the microscope, the fungoid mass is found to consist of short, beaded, tawny threads or filaments, arising from a common center, and having at their tips large spore-like cells.

Further notice of the parasitic diseases of the skin will be found in the articles PITIRIASIS (var. *versicolor*), RINGWORM, SCALD-HEAD, &c. The application of the Germ-Theory of disease would lead to the inclusion of many other diseases amongst parasitic disorders, in the wider sense of the word. Even specific fevers are by some so ranked. For diseases caused by the presence of the organisms known as bacteria, bacilli, &c., in the system, see GERM-THEORY.

PARASITIC PLANTS are plants which grow on other plants, and derive subsistence from their juices; the plants which live parasitically on animal tissues being generally called Entophytes (q. v.), although the distinction between these terms is not always preserved. Epiphytes (q. v.) differ from parasitical plants in not subsisting on the juices of the plant which supports them, but merely on decayed portions of its bark, &c., or drawing all their

nourishment from the air. Parasitical plants are numerous and very various; the greater number, however, and the most important, being small fungi, as Rust, Brand, Bunt, Smut, &c., the minute spores of which are supposed, in some cases, to circulate through the juices of the plants which they attack. Concerning some minute fungi, as the Mildews, it is doubted if they are truly parasitical, or if their attacks are not always preceded by some measure of decay. But among parasitic plants are not a few planerogamous plants, some of which have green leaves; and some are even shrubby, as the Mistletoe, Loranthus, &c., whilst the greater number have brown scales instead of leaves, as Dodder, Broom-rape, Lathræa, &c., and the whole of that remarkable order or class of plants called *Rhizanthæa* or *Rhizogens*, of which the genus *Rafflesia* is distinguished above all other plants for the magnitude of its flowers. Some parasitic plants, as the species of Dodder, begin their existence by independent growth from the ground; but when they have found suitable plants to take hold of and prey on, the connection with the ground ceases. Not a few, as Broom-rape and Lathræa, are root-parasites, generally attaching themselves to the roots of trees or shrubs; whilst some, as the Eyebright (*Euphrasia officinalis*), Yellow Rattle (*Rhinanthus crista galli*), Cow-wheat (*Melampyrum arvense*), &c., are parasitical only occasionally and partially, and are chiefly found on neglected grass lands. Root-parasites generally attach themselves by means of little tubercles, which bury themselves under the bark.

PARATY', a seaport town of Brazil, in the province of Rio de Janeiro, on the west coast of the Bay of Angra, 90 miles south-west of Rio de Janeiro city. It has extensive commerce, and numerous distilleries. Pop. said to be 10,000.

PARAY-LE-MONIAL, a town of Burgundy, department of Saône-et-Loire, celebrated for its Benedictine Abbey, founded in 973, which contains the tomb of Mary Margaret Alocque, the center of recent pilgrimages by the confraternities of the Sacred Heart (q. v.). Pop. of town and commune (1876), 3627; of town alone, 2895.

PAR'BUCKLE is a mode of drawing up or lowering down an inclined plane any cylindrical object, as a barrel or a heavy gun, without the aid of a crane or tackle. It consists in passing a stout rope round a post or some suitable object at the top of the incline,

Parbuckle.

and then doubling the ends under and over the object to be moved. This converts the cask or gun into a pulley in its own behalf, and limits the pressure at each end of the rope to one-fourth the weight of the object moved, as felt on the incline. By hauling in the ends equally, the cask ascends, or *vice versa*.

PAR'CE (from the root *pars*, a part), the name given by the Romans to the goddesses of Fate or Destiny, who assigned to every one his 'part' or lot. The Greek name, *Moiræ*, has the same meaning (from *meros*, a share). They are only once mentioned by Homer, who in every other instance speaks of Fate (*Moiræ*) in the singular, and whose Fate was not a deity but a mere personification, the destinies of men being made by him to depend upon the will of the gods; whilst, according to the later Greeks and the Romans, the gods themselves were subject to the control of the P. or *Moiræ*.

Hesiod, however, who is almost contemporary with Homer, speaks of three Fates, whom he calls daughters of Night—Clotho, the spinner of the thread of life; Lachesis, who determines the lot of life; and Atropos, the inevitable. They were usually represented as young women of serious aspect; Clotho with a spindle, Lachesis pointing with a staff to the horoscope of man on a globe, and Atropos with a pair of scales, or sun-dial, or an instrument to cut the thread of life. In the oldest representations of them, however, they appear as matrons, with staffs or sceptres. They had places consecrated to them throughout all Greece, at Corinth, Sparta, Thebes, Olympia, &c.

PARCELS, in the law of England, is the technical word for the article in a conveyance describing the lands, &c. conveyed.

PAR'CENER. See **COPARCENARY**.

PA'RBCHIM, a town of the grand-duchy of Mecklenburg-Schwerin, stands on the Elde, which is here divided into two arms, 23 miles south-east of Schwerin. It is very old, is irregularly built, surrounded by beautiful gardens, and has a gymnasium and two churches. Pop. (1880) 9063, employed in agriculture, in the manufacture of tobacco, cloth, leather, and brandy, and in weaving.

PA'RBCHMENT, one of the oldest inventions of writing materials was known at least as early as 500 years B.C. Herodotus speaks of books written upon skins in his time. Pliny, without good grounds, places the invention as late as 196 B.C., stating that it was made at Pergamos (hence the name *Pergamena*, corrupted into Eng. parchment) in the reign of Eumenius II., in consequence of Ptolemy of Egypt having prohibited the exportation of papyrus. Possibly the Perganian invention was an improvement in the preparation of skins which had certainly been used centuries before. The manufacture rose to great importance in Rome about a century B.C., and soon became the chief material for writing on; and its use spread all over Europe, and retained its pre-eminence until the invention of paper from rags, which from its great durability proved a fortunate circumstance for literature.

There are several kinds of parchment, prepared from the skins of different animals, according to their intended uses. The ordinary writing parchment is made from those of the sheep and of the she-goat; the finer kind, known as *vellum*, is made from those of very young calves, kids, and lambs; the thick common kinds, for drums, tambourines, battle-dores, &c., from those of old he-goats and she-goats, and in Northern Europe from wolves; and a peculiar kind is made from asses' skins, the surface of which is enamelled. It is used for tablets, as blacklead writing can be readily removed from it by moisture. The method of making parchment is at first the same as in dressing skins for leather. The skins are limed in the lime-pit until the hair is easily removed. They are then stretched tightly and equally, and the flesh side is dressed as in currying, until a perfectly smooth surface is obtained. It is next *ground* by rubbing over it a flat piece of pumice-stone, previously dressing the flesh side only with powdered chalk, and slaked lime sprinkled over it. It is next allowed to dry, still tightly stretched on the frame. The drying process is an important one, and must be rather slowly carried on, for which purpose it must be in the shade. Sometimes these operations have to be repeated several times, in order to insure an excellent quality, and much depends upon the skill with which the pumice-stone is used, and also upon the fineness of the pumice itself. When quite dried, the lime and chalk are removed by rubbing with a soft lamb-skin with the wool on.

PARCHMENT, VEGETABLE. This remarkable substance was made known by Mr. W. E. Gaine in 1854, and again by the Rev. J. Barlow in 1857. It resembles animal parchment so closely, that it is not easy to distinguish the difference. It is made from the water-leaf, or unsized paper, by immersing it only for a few seconds in a bath of oil of vitriol, diluted with one-half its volume of water. The exactness of this dilution is one of the greatest importance to the success of the results. The dilute acid must not be used immediately after mixing, but must be suffered to cool to the ordinary temperature; without attention to these apparently trifling points, the operator will not succeed.

The alteration which takes place in the paper is of a very remarkable kind. No chemical change is effected, nor is the weight increased; but it appears that a molecular change takes place, and the material is placed in a transition state between the cellulose of woody fibre and dextrin. Vegetable parchment is in some respects preferable to the old kinds, for insects attack it less, and it can be made so thin as to be used for tracing paper, and bears wet without injury. Messrs. De la Rue have the credit of giving practical effect to the invention.

PARDUBITZ, a town of Austria, in Bohemia, 61 m. E. of Prague. It has copper, iron, and paper manufactures. P. was the headquarters of the king of Prussia, 7th June 1866. Pop. (1880) 10,010.

PARÉ, AMBROISE, a renowned French surgeon, and the father of modern surgery, was born about the beginning of the 16th c., at Laval, department of Mayenne, France. His father, who was a trunk-maker, was unable to afford him a literary education, and apprenticed him to a barber and surgeon. P., after a brief term of service, acquired such a fondness for surgery and anatomy, that, abandoning his master, he went to Paris to prosecute his studies. His means for doing so were very limited; he could afford to obtain instruction from only the more obscure teachers; few books were within his reach, yet by dint of perseverance and the exercise of a rare discrimination, combined with the valuable practice in the Hôtel de Dieu of Paris, he laid a solid foundation for future eminence. In 1536, P. was received as a master barber-surgeon, and joined in this capacity the army of Marshal

René de Monte-Jean, which was on the point of starting for Italy. During this campaign he improved the mode of treatment of gun-shot wounds, which had up to this time been of the most barbarous kind—namely, cauterization with boiling oil. His reputation as well as his skill were greatly heightened during this campaign, and as he himself says: 'If four persons were seriously wounded I had always to attend three of them; and if it were a case of broken arm or leg, fractured skull, or fracture with dislocation, I was invariably summoned.' In 1539, he returned to Paris, whither his high renown had preceded him, and was received with distinction by the Royal College of Chirurgery, of which he was subsequently appointed president. On the war being renewed, he was again attached to the army under the Viscount de Rohan, afterwards under Antoine de Bourbon, Duke of Vendôme. It was during this campaign that he cured François, the second Duke of Guise, of the wound which conferred upon him the sobriquet of *Balafré*, and that he substituted ligature of the arteries for cauterization with a red-hot iron after amputation. The idea of this mode of repressing hemorrhage had long been in existence, but he was the first to show that it could safely be applied to practice. Many other important improvements in surgery were introduced by him at this time.

In September 1552 he was appointed surgeon to King Henry II., and in the following year was taken prisoner at Hesdin; he was however released, in consideration of his having cured Colonel de Vaudeville, after rejecting the brilliant offers made him by the Duke of Savoy to remain in his service. Returning to Paris, honors were showered upon him; and though he was ignorant of Latin, the *conditio sine qua non* of a liberal education at that time, no hesitation was shown in conferring upon him learned titles and degrees. He attended Francis II. on his death-bed, and continued to hold the office of king's surgeon to his successors, Charles IX. and Henry III. The former of these monarchs, whose life had been gravely threatened by an injury inflicted by his physician Portail, and who had been preserved by P., testified for him the greatest esteem, and saved him during the massacre of St. Bartholomew by locking him up in his own chamber. During the latter part of P.'s life, he was much employed in the publication of his various writings, and suffered considerable annoyance from the envious spirit displayed towards him by his professional brethren, who showered obloquy upon him for having, as they said, 'dishonored science by writing in the vulgar tongue.' P. died at Paris, December 22, 1590. His writings have exercised a great influence on the practice of surgery in all countries to which they have penetrated, and are held of the highest authority on the subject of gun-shot wounds. The first complete edition of them appeared at Lyon in 1562, and the last, edited by M. Malgaigne, at Paris (1840—1841, 3 vols.). Besides these are 8 Latin editions, and more than 15 translations into English, Dutch, German, &c. As an instance of his great popularity in the army, it may be mentioned that the soldiers of the garrison of Metz, of their own accord, gave him a triumphal reception on his entering that town.

PAREGORIC, or **PAREGORIC ELIXIR** (from the Gr. *paregoricos*, soothing), the *Compound Tincture of Camphor* of the London, and the *Camphorated Tincture of Opium* of the British Pharmacopœia, consists of an alcoholic solution of opium, benzoic acid, camphor, and oil of anise, every fluid ounce containing two grains of opium and benzoic acid, and a grain and a half of camphor. This preparation is much used both by the profession and the public. In doses of from one to three drachms, it is an excellent remedy for the chronic winter-cough of old people, the opium diminishing the bronchial secretion and the sensibility of the pulmonary mucous membrane, while the benzoic acid and oil of anise act as stimulating expectorants. It has also been found useful in chronic rheumatism.

PAREIRA-BRAVA. See **CISSAMPELOS**.

PARELLA (Fr. *parelle* or *perelle*), a name often given to some of those crustaceous lichens which are used to produce Archil, Cudbear, and Litmus; but which more strictly belongs to one species, *Lecanora parella*, resembling the Cudbear, Lichen, but with somewhat plated warty crust, and shields (*apothecia*) having a concave disk of the same color as the thick tumid even border. Like the Cudbear Lichen—to which it is far superior in the quality of the dye-stuff obtained from it—it grows on rocks in mountainous districts both in Britain and on the continent of Europe, being particularly abundant in Auvergne and other parts of France.

PARENCHYMA. See **CELLULAR TISSUE**.

PARENT AND CHILD. The legal relation between parent and child is one of the incidents or consequences of the relation of husband and wife, and flows out of the contract of marriage. The legal is to be distinguished from the natural relation, for two persons may be by the law of nature parent and child, while they are not legally or legitimately so. Hence a radical distinction

exists between natural or illegitimate and legitimate children, and their legal rights as against their parents respectively are very different. Legitimate children are the children of two parents who are recognized as married according to the laws of the country in which they are domiciled at the time of the birth; and according to the law of England, if a child is illegitimate at the time of the birth, nothing that can happen afterwards will ever make it legitimate, the maxim being 'once illegitimate always illegitimate'—a maxim which, as will be stated, has some exceptions in Scotland. In treating of the laws affecting the mutual relation of parent and child, the laws of England and Ireland, which differ from the law of Scotland in material respects, will first be stated.

1. *As to Legitimate Children*.—These laws relate first to the liability of the parent to maintain the child, and the rights of the child in the event of the parent's death. As regards the maintenance of the child, it is somewhat singular that, according to the law of England, there is no duty whatever on the parent to support the child, and consequently no mode of enforcing such maintenance. The law of nature was probably considered sufficient to supply the motives which urge a parent to support the child, but the municipal law of England has not made this duty compulsory. This defect was to some extent remedied when what is called the Poor-Law was created by statute in the reign of Elizabeth, by which law parents and children are compellable to a certain small extent, but only when having the pecuniary means to do so, to support each other, or rather to help the parish authorities to do so. But apart from the Poor-Law statutes, there is no legal obligation on the parent to support the child, nor on the child to support the parent. Hence it follows, that if the child is found in a destitute state, and is taken up, fed, and clothed, and saved from starvation by a stranger, such stranger cannot sue the parent for the expense, or any part of it, however necessary to the child's existence.

In order to make the father liable for maintenance, there must in all cases be made out against him some contract, express or implied, by which he undertook to pay for such expense; in other words, the mere relationship between the parent and child is not of itself a ground of liability. But when the child is living in the father's house, it is always held by a jury or court that slight evidence is sufficient of, at least, an implied promise by the father to pay for such expenses. As, for example, if the child orders clothes or provisions, and the father see these in use or in process of consumption, it will be taken that he assented to and adopted the contract, and so will be bound to pay for them. So if a parent put a child to a boarding-school, very slight evidence of a contract will be held sufficient to fix him with liability. Nevertheless, in strictness of law, it is as necessary to prove a contract or agreement on the part of the parent to pay for these expenses as it is to fix him with liability in respect of any other matter. When it is said that a parent is not compellable by the common law to maintain his child, it must, at the same time, be observed that if a child is put under the care and dominion of an adult person, and the latter wilfully neglect or refuse to feed or maintain such child, whereby the child dies or is injured, such adult will incur the penalties of misdemeanor; but this offence does not result from the relationship of parent and child, and may arise between an adult and child in any circumstances, as where a child is an apprentice or servant.

The change as to the liability of parents to maintain their children created by the Poor-Laws amounts merely to this, that if a person is chargeable to the parish, that is, not able to work as well as destitute, and if the overseers or guardians are bound to support him or her, then the parish authorities may reimburse themselves this outlay, or part of it, by obtaining from justices of the peace an order commanding the parent or child of such pauper to pay a certain sum per week towards the relief. This is, however, only competent when the relative is able to pay such sum, and in all cases the sum is of necessity very small. Not only parents, but grand-parents, are liable under the Poor-Law Act to the extent mentioned. Another provision in the Poor-Law and other kindred acts is, that if a parent runs away and deserts his children, leaving them destitute and a burden on the parish, the overseers are entitled to seize and sell his goods, if any, for the benefit and maintenance of such children; and if the parent, so deserting the children, is able by work or other means to support them, such parent may be committed to prison as a rogue and vagabond. Not only, therefore, is a parent during life not bound to maintain his or her child (with the above exceptions), but also after the parent's death the executors or other representatives of the parent, though in possession of funds, are not bound. It is true that if the parent die intestate, both the real and personal property will go to the children; but the parent is entitled, if he choose, to disinherit the children, and give away all his property to strangers, provided he execute his will in due form, which he may competently do on death-bed if in possession of his faculties.

Another important point of law, affecting the mutual relation of parent and child, is the right of the parent to the custody of

the child. At common law it is the father who has the right to the custody of the child until majority at least, as against third parties, and no court will deprive him of such custody except on strong grounds. Whenever the child is entitled to property, the Court of Chancery so far controls his parental right, that if the father is shown to act with cruelty, or to be guilty of immorality, a guardian will be appointed. A court of common law also has often to decide in cases of children brought before it by *habeas corpus*, when parties have had the custody against the father's will. In such cases, if the child is under fourteen, called the age of nurture, and the father is not shown to be cruel or immoral, the court will order the child to be delivered up to him; but if the child is above fourteen, or, as some say, above sixteen, the court will allow the child to choose where to go. So the father is entitled by his will to appoint a guardian to his children while they are under age. The mother had, at common law, no right as against the father to the custody of the children, however young; but under a statute of 36 and 37 Vict. c. 12, she is entitled to the custody of the child while under sixteen years of age, or rather she is entitled to apply to the Court of Chancery for leave to keep the children, while under that age, provided she is unobjectionable in point of character; and access may be allowed to the father or guardian. If the parents separate by agreement, no stipulation will be enforced which is prejudicial to the child. In case of divorce or judicial separation, the Court of Divorce has power to direct who is to have the custody of the children.

2. *Illegitimate Children.*—It has been already stated that, at common law, the parent of a legitimate child is not bound to maintain it, and this is equally true of an illegitimate child—i. e., a child born not in wedlock. In strictness of law, an illegitimate child has no father, which means practically that in case of the death of the father without making a will, the law will not treat such child as entitled to the ordinary legal rights of a legitimate child—i. e., to a share of the father's property. The child is not legally related to the father in this sense. With regard to the mother, she also is not bound to maintain her child according to the common law; but the Poor-Law acts have made an important qualification of her rights and duties. As between the father and mother of the child, the law is this: The father is not bound even by the Poor-Laws to maintain the child, and the parish officers cannot now institute any proceeding whatever against him for this purpose; but the mother can, to a certain extent, enforce against him a contribution towards the child's maintenance and education, or the guardians may do so. It is entirely discretionary on the mother to take any proceeding against the father, but if she chooses she can do so; and the first step is to go before a justice of the peace and obtain a summons of affiliation. The father is thus cited before the magistrate, and if the mother swears that he is the father of the child, and is corroborated in some material part of this statement by a third party, the magistrate may make an order against the father to pay the expenses of lying-in, and a weekly sum not exceeding five shillings till the child attains the age of sixteen. The mother may make this application either a few months before the birth, or within twelve months after the birth; and even after that time, provided she can prove that the putative father paid her some money on account of the child within such twelve months. The putative father, in these cases, is a competent and compellable witness.

The utmost, therefore, that the father can be made to contribute towards the child's maintenance is only a portion of the whole, the chief burden being thrown on the mother, who is assumed to be the more blameable party. Though she is not bound by the common law to maintain her child, yet the Poor-Laws make her liable to maintain the child till it attains sixteen; and not only is she bound, but any man who marries her is also by statute bound to support all her illegitimate (and also legitimate) children till they attain sixteen. The result is, that illegitimate children under sixteen are better provided for by the present state of the law than legitimate children, inasmuch as the mother is positively bound to support her illegitimate child, and only to a less extent her legitimate child. As regards the custody of illegitimate children, the mother is the party exclusively entitled, for the father is not deemed, in point of law, to be related to such child. Yet if the father has, in point of fact, obtained the custody of such child, and the child is taken away by fraud, the courts will restore the child to his custody, so as to put him in the same position as before. Though illegitimate children will not succeed to the father's property in the event of his dying without a will, there is nothing to prevent him making his will in their favor, provided he expressly name and identify them, and not leave it to them by the description of 'his children,' which in point of law they are not.

Scotland.—The law of parent and child in Scotland differs materially from the law of England and Ireland. In Scotland, a child may be born a bastard, and yet if the parents afterwards marry, this will legitimize the child, and give the child the right to succeed to the father's property. A difficulty sometimes

arises where, before the father and mother of a bastard marry, the father has had a legitimate family by another woman, in which case it is held that the bastard, though oldest in point of age, does not take precedence of the legitimate children. The law of Scotland also differs from that of England as regards the obligation of parent and child to maintain each other. There is a legal obligation on both parties to maintain each other if able to do so, and either may sue the other for aliment at common law; but this obligation extends only to what may be called subsistence money, and does not vary according to the rank of the party. Thus an earl is bound to pay no more for the aliment of his son than any other father. As regards all maintenance beyond mere subsistence, the law does not materially differ from that of England, and a contract must be proved against the father before he can be held liable to pay. The legal liability as between parent and child is qualified in this way by the common law, that if a person has both a father and a child living and able to support him, then the child is primarily liable, and next the grandchild, after whom comes the father, and next the grandfather. Not only are parent and child liable to support each other while the party supporting is alive, but if he die, his executors are also liable; and this liability is not limited by the age of majority, but continues during the life of the party supported. Such being the common law of Scotland, it was scarcely necessary, as in England, for the Poor-Law to supply any defect; but the Scotch Poor-Law supplements the common law, by imposing a penalty on a father or mother (though *not vice versa*) who neglects to support a child.

Another advantage which a Scotch child has over an English child is, that the father cannot disinherit it—at least so far as concerns his movable property; and even in case of heritable property, the rights of the child were so protected, that unless the father made away with his heritable property sixty days before his death, or while in sound health, it was too late to prejudice his heir-at-law; this rule was, however, abolished in 1870 by 34 and 35 Vict. c. 81. This was called the Law of Deathbed (q. v.); but as regards the father's movable property, he cannot by any will he can make at any time of his life deprive the children of one-third, or, if their mother is dead, of one-half of such property. This is called the children's right to Legitim (q. v.), a right which they can vindicate, whatever may be their age when their father dies. With regard to the custody of children in Scotland, the rule is, that the father is entitled to the custody as between him and the mother; but the Court of Session has power to regulate the custody in case the children are entitled to property, and the father is of an immoral or cruel character; and the court will also interfere to allow to the mother access to the children at certain times and seasons. Another important difference between a Scotch and English child is this, that whereas in England the father or guardian, or the Court of Chancery, has power to control the custody of the person of the child to a certain extent, until the child attains the age of 21, in Scotland such power entirely ceases when the child attains the age of 14 or 12, according as such child is male or female. At the age of 14, a boy, and at 12, a girl, in Scotland, is entire master or mistress of his or her movements, and can live where he or she pleases, regardless of any parent or court. They can marry at that age at their own uncontrolled discretion, and act in all respects with the same freedom as adults. As regards the disposition of their property there are some restrictions, but as regards the disposal of their persons there are none, after the ages of 14 and 12 respectively.

2. *Illegitimate Children.*—The law of Scotland as to illegitimate children also differs in some respects from that of England. Both the father and mother of a bastard are bound by law to support such child, and the obligation transmits to the personal representatives of the father or mother. Moreover, by the Poor-Law statute both are liable to a penalty for neglecting to support the child. The mother of illegitimate children is entitled to their custody till the age of ten, if daughters, and if sons, till the age of seven; but the limit is not clearly defined. If the father support the child after the above age, he is entitled to the custody. The mother does not apply to a magistrate for a summons of affiliation in order to fix the paternity; but she may bring an action of filiation and aliment, in which the question of paternity is settled. The father may be judicially examined, and is a competent witness; and it is usual for the court to decree an aliment, varying from £4 per annum against laborers, up to £10 against persons in better circumstances. In Scotland, as in England, the father of a bastard child is not deemed related, in point of law, to such child; and if he desires to provide for such child, it must be done by deed or will, in which the child is identified, and not merely described under the general designation of 'child,' which he is not.

PARENTHESIS, a term originally Greek, and signifying *insertion* or *intercalation*, is in composition a clause, or part of a sentence or argument, not absolutely essential to the sense, but

generally serving either for explanation or confirmation, sometimes chiefly for rhetorical effect. A parenthesis is usually included between the marks (), instead of which the dash (—) at the beginning and end of the parenthesis is frequently but improperly employed.

PARHELION. See HALOS.

PA'RIAH DOG. See CUR.

PARIAN CHRONICLE. See ARUNDEL MARBLES.

PA'RIAS is the name given to the lowest class of the population of India—to that class which, not belonging to any of the castes of the Brahminical system, is shunned even by the lowest Hindu professing the Brahminical religion, as touching a Paria would render him impure. The P. seem to belong to a negro race, as appears from their short woolly hair, flat nose, and thick lips; they are, besides, of short stature, and their propensities are of the coarsest kind. Despised by the Hindus, and ill used by the conquerors of India, they have, in some parts of India, gradually sunk so low that, to judge from the description which is given of their mode of living by different writers, it is scarcely possible to imagine a more degraded position than that which is occupied by these miserable beings.

PA'RIDÆ AND PARUS. See TIT.

PARING AND BURNING consists in cutting off the surface of the soil in thin slices, which are then dried and burned. This is the most effectual way of reclaiming peat and other waste land, the surface of which is matted with coarse plants, difficult of decay. It is also applied advantageously to cold clay soils, apt to produce rank weeds and coarse grasses, which are to be broken up after lying for some time in grass. The ashes of the plants, consisting of potash and other salts, act as a powerful manure; while the clay being reduced to the state of brick-dust, both improves the texture of the soil, and acts as an absorbent for retaining moisture and nutritive gases, and giving them out to the roots of growing plants. On thin light soils the operation is rarely advisable, for much of the scanty volatile vegetable matter is dissipated; however if care is taken to make the turfs merely smoulder without flame, so that the plants are rather charred than burned, it is doubtful whether more dissipation takes place than if the plants were ploughed down, and allowed slowly to decay. The plot to be reclaimed should, if necessary, be dried by stone or tile drains; and all large stones grubbed up, and carted or conveyed off upon sledges. The paring is to be done, if possible, in the months of April and May, in order to have the most favorable part of the year for drying the parings well before burning.

There are ploughs specially made for paring, with a very flat share; but the best method is to employ the *breast-plough* or *paring-spade*, as the surface is in most cases very irregular, and it is desirable to have the slices very thin. The parings should be burned directly they are sufficiently dry, as, after laying a month or six weeks, they begin to unite with the ground, and imbibe moisture from the young grass vegetating beneath them. Sometimes they can be burned as they lie, without being collected into heaps; and in this way, the fire, in consuming the liny side, which is undermost, chars the surface of the soil at the same time. If burned in heaps, the heaps should be very small, in order to secure a good black ash, instead of the hard lumps of red ash produced by large fires. The weeds or refuse organic matters are thus only charred, instead of being entirely burned away; whilst the mineral matters are left in a soluble state instead of being reduced, as it is too apt to be the case where the operation is carelessly conducted, into an insoluble semi-vitrified slag. To attain these desirable results a smouldering fire must be maintained, by keeping the outside layer of sods so close as to prevent the fire from kindling into flame. The ashes should be spread, care being taken to clear the bottoms of the heaps well out, so that the first crop may be free from patches. The cost of thus paring, burning, and spreading is about £1 per acre.

PA'RIAS, a genus of plants of the small endogenous or dictyogenous natural order *Trilliacæ*, of which one species, *P. quadrifolia*, called HERB PARIS, is not uncommon in moist shady woods in some parts of Britain. It is rarely more than a foot high, with one whorl of generally four leaves, and a solitary flower on the top of the stem, followed by a berry. The berry is reputed narcotic and poisonous, but its juice has been employed to cure inflammation of the eyes. The root has been used as an emetic.

PARIS, also called ALEXANDER, was, according to Homer, the second son of Priam and Hecabe, sovereigns of Troy. His mother dreamed during her pregnancy that she gave birth to a firebrand, which set the whole city on fire, a dream interpreted by Æacus or Cassandra to signify that P. should originate a war which should end in the destruction of his native city. To prevent its realization, Priam caused the infant to be exposed upon Mount Ida by a shepherd named Agelaus, who found him, five days after, alive and well, a she-bear having given him suck. Agelaus brought him up as his own son, and he became a shepherd on

Mount Ida, distinguishing himself by his valor in protecting the other shepherds from their enemies—whence his name, Alexander, 'the defender of men.' An accident having revealed his parentage, old Priam became reconciled to his son, who married Ænone, daughter of the river-god Cebren. But his mother's dream was to come true for all that. He was appealed to, as umpire, in a strife which had arisen among the three goddesses, Hera (Juno), Athene (Minerva), and Aphrodite (Venus), as to which of them was the most beautiful, the goddess Eris (Strife) having revengefully flung among them, at a feast to which she had not been invited, a golden apple (of discord) inscribed *To the Most Beautiful*. Each of the three endeavored to bribe him. Hera promised him dominion over Asia and wealth; Athene, military renown and wisdom; Aphrodite, the fairest of women for his wife—to wit, Helene, the wife of the Lacedæmonian king, Menelaus. P. decided in favor of Aphrodite, hence the animosity which the other two goddesses displayed against the Trojans in the war that followed. P. now proceeded to seek Helene, whom he carried away from Lacedæmon in her husband's absence. 'The rape of Helen' is the legendary cause of the Trojan war, on account of which P. incurred the hatred of his countrymen. He deceitfully slew Achilles in the temple of Apollo. He was himself wounded by a poisoned arrow, and went to Mount Ida to be cured by Ænone, who possessed great powers of healing; but she avenged herself for his unfaithfulness to her by refusing to assist him, and he returned to Troy, and died. He was often represented in ancient works of art generally as a beardless youth, of somewhat effeminate beauty.

PARIS (the ancient *Lugetia Parisiorum*), the metropolis of France, is situated in 48° 50' N. lat., and 2° 20' E. long., on the Seine, about 110 miles from its mouth. Pop. (1869) 1,875,000; (1872) 1,799,250; (1876) 1,988,806; and at the end of 1881, 2,269,023. Its circumference is upwards of 25 miles. It lies in a hollow about 200 feet above the level of the sea, and is surrounded by low hills, which in their highest ranges to the north only attain an elevation of 290 or 300 feet, as at Montmartre and Belleville. These hills, which are separated by narrow valleys or plateaux, as those of St. Denis to the north, Ivry to the east, Montrouge to the south, and Grenelle to the south-west, are encircled at a distance of from two to five miles by an outer range of heights, including Villejuif, Meudon, St. Cloud, and Mont-Valérien, the highest point in the immediate vicinity of the city. The Seine, which enters P. in the south-east at Bercy, and leaves it at Passy in the west, divides the city into two parts, and forms the two islands of La Cité and St. Louis, which are both covered with buildings.

The earliest notice of P. occurs in Julius Cæsar's *Commentaries*, in which it is described under the name of Lutetia, as a collection of mud huts, composing the chief settlement of the Parisii, a Gallic tribe, conquered by the Romans. The ruins of the Palatium Thermarum (Palais des Thermes), and of ancient altars, aqueducts, and other buildings, show that even in Roman times the town extended to both banks of the Seine. Lutetia began in the 4th c. to be known as Parisia, or P., from the Celtic tribe of the Parisii, to whom it belonged. In the 6th c., P. was chosen by Clovis as the seat of government; and after having fallen into decay under the Carlovingian kings, in whose time it suffered severely from frequent invasions of the Norsemen, it finally became in the 10th c. the residence of Hugh Capet, the founder of the Capetian dynasty, and the capital of the Frankish monarchy.

From this period, P. continued rapidly to increase, and in two centuries it had doubled in size and population. In the middle ages, P. was divided into three distinct parts—La Cité, on the islands; the Ville, on the right bank; and the Quartier Latin, or University, on the left bank of the river. Louis XI. did much to enlarge P., and to efface the disastrous results of its hostile occupation by the English during the wars under Henry V. and Henry VI. of England; but its progress was again checked during the wars of the last of the Valois, when the city had to sustain several sieges. On the accession of Henri IV. of Navarre, in 1589, a new era was opened to Paris. The improvements commenced under his reign were continued under the minority of his son, Louis XIII. Louis XIV. converted the old ramparts into public walks or *boulevards*, organized a regular system of police, established drainage and sewerage works, founded hospitals, almshouses, public schools, scientific societies, and a library, and thus gave to P. a claim to be regarded as the focus of European civilization. The terrible days of the Revolution caused a temporary reaction. The improvement of P. was recommenced on a new and grander scale under the first Napoleon, when new quays, bridges, markets, streets, squares, and public gardens were created. All the treasures of art and science which conquest placed in his power were applied to the embellishment of P., in the restoration of which he spent more than £4,000,000 sterling in twelve years. His downfall again arrested progress, and in many respects P. fell behind other European cities.

Renovation of various sorts was recommenced under Louis-Philippe; but as lately as 1834, much of the old style of things remained; the gutters ran down the middle of the streets, there was little underground drainage from the houses, oil-lamps were suspended on cords over the middle of the thoroughfares, and, except in one or two streets, there were no side-pavements. It was reserved for Napoleon III. to render P. the most commodious, splendid, and beautiful of modern cities. When he commenced his improvements, P. consisted, in the main, of a labyrinth of narrow, dark, and ill-ventilated streets. He resolved to pierce broad and straight thoroughfares through the midst of these, to preserve and connect all the finest existing squares and boulevards; and in lieu of the old houses pulled down in the heart of the town, to construct, in a ring outside of it, a new city in the most approved style of modern architecture. With the assistance of Baron Haussman, the Prefect of the Seine, his schemes were carried out with rare energy and good taste. Two straight and wide thoroughfares, parallel to and near each other, crossed the whole width of Paris from north to south through the Cité; a still greater thoroughfare was made to run the whole length of the town, north of the Seine, from east to west. The old boulevards were completed so as to form outer and inner circles of spacious streets—the former chiefly lying along the outskirts of the old city, the latter passing through and connecting a long line of distant suburbs. In the year 1867, when the international exhibition was opened, P. had become in all respects the most splendid city in Europe; and in that year it was visited by upwards of a million and a half of foreigners. Many further improvements were then contemplated. New botanical and zoological gardens were to be formed; the museums and class-rooms of the Jardin des Plantes were to be rebuilt; an underground railway was to be formed, crossing P. from east to west; Montmartre was to be levelled, and the Seine was to be deepened up to Grenelle, the point where it leaves the town; and there a harbor was to be formed for sea-going ships, which was to convert P. into a *port de mer*. Financial and political difficulties were, however, at hand (see FRANCE), and these great schemes had to be postponed.

The siege of P. by the Germans, which lasted from 19th September 1870 to 28th January 1871, caused much less injury to the city than might have been expected—it was reserved for a section of the Parisian population to commit an act of Vandalism without a parallel in modern times. On the 18th of March, the Red Republicans, who had risen against the government, took possession of Paris. On the 27th March, the Commune was declared the only lawful government. Acts of pillage and wanton destruction followed. On the 15th of May, the column erected to the memory of Napoleon and the Great Army, in the Place Vendôme, one of the principal squares of P., was solemnly pulled down as a 'monument of tyranny.' The government troops under Marshal McMahon attacked the insurgents, and kept them from doing further mischief. The former succeeded in entering Paris on the 20th of May, and next day the Communists began systematically to set fire with petroleum to a great number of the chief buildings of P., public and private. The fire for a time threatened to destroy the whole city. It raged with the greatest fury on the 24th, and was not checked until property had been lost to the value of many millions sterling, and historical monuments were destroyed which never can be replaced. The horror inspired by the Commune for a time drove the wealthy classes from Paris, and it was feared that it would lose its prestige as a European capital. This, however, has not proved to be the case. In the autumn of 1873, all the private houses burnt had been rebuilt—the monuments only partially injured had been restored, and the streets and public places were as splendid and gay as in the best days of the Empire. There remained, however, to recall the Commune, the blackened ruins of the Tuileries, the Hôtel de Ville, and two or three other buildings to which we are about to refer.

The Seine, in passing through P., is spanned by 28 bridges. The most celebrated and ancient are the Pont Notre-Dame, erected in 1600, and the Pont-Neuf, begun in 1578, completed by Henri IV. in 1604, and thoroughly renovated in 1852. This bridge, which crosses the Seine at the north of the Ile-de-la-Cité, is built on 12 arches, and abuts near the middle on a small peninsula, jutting out into the river, and planted with trees, which form a background to the statue of Henri IV. on horseback, which stands in the central open space on the bridge. Among the other bridges, the handsomest are the Pont de la Concorde, 160 yards long, built in 1787–1790; the Pont du Carrousel, Pont d'Austerlitz, and the Pont d'Jéna, both of the time of the First Empire; and the Pont des Invalides, Pont de l'Alma, and Pont de Solférino—all handsome structures, adorned with military and naval trophies, commemorative of events and victories connected with the Second Empire. These bridges all communicate directly with the spacious quays, planted with trees, which line both banks of the Seine, and which, together with the Boulevards, give special characteristic beauty to the city. Although the most ancient quays—as those des Augustins and de la Mégisserie—date from the 14th c.,

the greater part of these magnificent embankments measuring 12 miles in extent, is due to the first Napoleon and the late emperor.

Before speaking in detail of the streets, boulevards, and places or squares of P., it is proper to mention that the private houses as well as the public buildings are built of a light-colored kind of limestone, easily wrought and carved ornamentally. With this material, they are reared in huge blocks, rising to a height of six or seven stories; each floor constituting a distinct dwelling; access to all the floors in a tenement being gained by a common stair, which is usually placed under the charge of a porter at the entrance.

Very frequently, the tenements surround an open quadrangle, to which there is a spacious entry, the gate of which is kept by a porter for the whole inhabitants of the several stairs. In these respects, therefore, P. differs entirely from London; for instead of extending rows of small brick buildings of a temporary kind over vast spaces, the plan consists of piling durable houses on the top of each other, and confining the population to a comparatively limited area. In the great new streets which were formed in the time of the late emperor, this general plan has been adhered to, but with this difference, that instead of being narrow and crooked, they are wide and straight. Among the finest of them are the Rue de Rivoli, two miles in length, the Rue de la Paix, the Rue du Faubourg St. Honoré, and the Rue Royale. The Boulevards, which extend in a semicircular line on the right side of the Seine, between the nucleus of the city and its surrounding quarters, present the most striking feature of Paris life. In all the better parts of the city they are lined with trees, seats, and little towers called *Vespasiennes*, covered with advertisements. Restaurants, cafés, shops, and various places of amusement succeed one another for miles, their character varying from the height of luxury and elegance in the western Boulevard des Italiens, to the homely simplicity of the eastern Boulevards Beaumarchais and St. Denis. Among the public squares or *places*, the most noteworthy is the Place de la Concorde, which connects the Gardens of the Tuileries with the Champs-Élysées, and embraces a magnificent view of some of the finest buildings and gardens of Paris. In the center is the famous obelisk of Luxor, covered over its entire height of 73 feet with hieroglyphics. It was brought from Egypt to France, and in 1836 placed where it now stands. On the site of this obelisk stood the revolutionary guillotine, at which perished Louis XVI., Marie Antoinette, Philippe Egalité, Danton, Robespierre, and a host of other victims.

Of the other squares, the following are some of the most handsome: the Place du Carrousel, between the Tuileries and Louvre; the Place Vendôme, already referred to, with Napoleon's Column of Victory; the Place de la Bastille, where once stood that famous prison and fortress; the Place Royale, with its two fountains and a statue of Louis XIII.; the Place de l'Hôtel de Ville, formerly Place de la Grève, for many ages the scene of public executions, and the spot at which some of the bloodiest deeds of the Revolution were perpetrated. The Porte St. Martin and Porte St. Denis, which were erected by Louis XIV. to commemorate his victories in the Low Countries, and are adorned with bas-reliefs representing events of these campaigns, marked the ancient limits of the most turbulent quarters of the Paris of the past; while the Arc de l'Etoile, begun by Napoleon in 1806, and completed in 1836 at a cost of more than £400,000, may be said to form the extreme western boundary of the aristocratic quarters. This arch, which bounds the Champs-Élysées, has a total height of 152 feet, and a breadth of 137. It is profusely adorned with bas-reliefs and alto-reliefs, representing victories of Napoleon, which were injured during the bombardment of Paris, but which have since undergone a complete restoration. The great streets which radiate from the Arc de Triomphe were among the most magnificent of those constructed during the recent improvements, and they still form the finest quarter of Paris. A great avenue runs east from it to the Palace of the Tuileries, in the heart of the city.

The Palace of the Tuileries (q. v.) was begun in 1566 by Catherine de' Medici, and enlarged by successive monarchs, while used as a royal residence, until it formed a structure nearly a quarter of a mile in length, running at right angles to the Seine. To the east of the Tuileries, at a distance of more than a quarter of a mile, was erected the palace of the Louvre, forming a square of 576 feet by 588 feet, remarkable, especially the eastern façade, for its architectural beauty. The Louvre long since ceased to be a royal residence, and has been converted into a public museum of antiquities. It was connected with the Tuileries by a great picture gallery overlooking the Seine, and 1456 feet in length. North of the picture gallery, and between the two palaces, lay the Place du Carrousel, into the northern side of which, at the accession of Napoleon III., there intruded a mass of poor and narrow streets. One of the emperor's earliest improvements was to remove these buildings, and connect the Tuileries and Louvre on the northern side, throwing them into one vast building, forming the most

magnificent palatial structure in the world. The Tuileries continued to be occupied as the residence of the imperial family; but the Louvre proper formed a series of great galleries filled with pictures, sculptures, and collections of Egyptian, Greek, and Roman antiquities. The Communists attempted to burn the whole pile, but only succeeded in destroying the Tuileries (of which the main part is not to be rebuilt), and a corner of the Louvre. The library of the Louvre, with its contents, was burned, but the rest of the building and its priceless treasures were saved. A large sum was voted by the government for the restoration of the Louvre, and this work was at once undertaken and carried forward with the utmost despatch. North of the injured part of the Louvre is the Palais Royal (q. v.), the most valuable part of which, fronting the Rue St. Honoré, was set fire to by order of the Commune in 1871. The Palace of the Luxembourg, on the south side of the Seine, was built by Marie de' Medici in the Florentine style. It contains many magnificent rooms, some of which have been employed as picture galleries for the works of modern artists.

The Luxembourg was formerly the House of the Peers, after 1871 was used as the Prefecture of the Seine, and in 1879 became the meeting-place of the French Senate. On the north bank of the Seine, opposite the island of the Cité, stood the old Hôtel de Ville, which, before its destruction by the Commune, was one of the most magnificent buildings in Paris. It was the residence of the Prefect of the Seine, who held a sort of court there, and it included all the offices for the transaction of the municipal business of Paris. It was commenced under Francis I., but had been trebled in extent by recent additions. The statues and rich ornaments with which it was decorated were almost entirely destroyed, but steps were immediately taken to have the Hôtel carefully rebuilt in the style of its predecessor. On the island of the Cité stands the Palais de Justice, a vast building, also set fire to by the Commune; some parts of it date from the fourteenth century, and others are modern. It is the seat of some of the courts of law, as the Courts of Cassation, of Appeal, and of Police. The old Palace was not much injured by the fire; but the new portion (again rebuilt) which was constructed during the reign of Napoleon III., and much admired for its architecture, was left in ruins. Within the precincts of this palace are the Sainte Chapelle, and the noted old prison of the Conciergerie, in which Marie Antoinette, Danton, and Robespierre were successively confined.

The Conciergerie, just mentioned, in which prisoners are lodged pending their trial, constitutes one of the eight prisons of P., of which the principal is La Force. The Nouveau Bicêtre is designed for convicts sentenced to penal servitude for life; St. Pélagie receives political offenders, St. Lazare is exclusively for women, the Madelonnettes for juvenile criminals, and Clichy for debtors.

The number of the institutions of benevolence is enormous. The largest of the numerous hospices or alms-houses is La Salpêtrière, probably the largest asylum in the world, extending over 78 acres of land, and appropriated solely to old women, 1800 of its 4500 inmates being insane patients; Bicêtre, with nearly 3600 beds, receives only men. The Hospice des Enfants Trouvés, or Foundling Hospital, provides for the infants brought to it till they reach the age of maturity, and only demands payment in the event of a child being reclaimed. The Crèches, or public nurseries, first established in 1844, of which there are now 18, receive the infants of poor women for the day at the cost of 20 centimes. Besides institutions for the blind, deaf and dumb, convalescents, sick children, &c., P. has 17 general and special hospitals. Of these the oldest and most noted are the Hôtel Dieu, receiving annually 13,000 patients; La Charité, and La Pitié.

The chief institutions connected with the University of France, and with education generally, are still situated in the Quartier Latin. The Sorbonne (q. v.), a large building erected by Cardinal Richelieu for the faculties of the old university of Paris, contains lecture-halls and class-rooms, and an extensive library open to the public. There degrees are granted by the University of France in the faculties of science, letters, and theology, and gratuitous public lectures are delivered, which are attended by a large number of students. Near Sorbonne is the Collège de France, where gratuitous lectures are also delivered by eminent scholars and men of letters. The Ecole Polytechnique, the School of Medicine and the School of Law, the Observatory, and the Jardin des Plantes, with its great museum of natural history, lecture-rooms, and botanical and zoological gardens, are situated in the same quarter of Paris.

The principal of the public libraries are those of the Rue Richelieu, now called the Bibliothèque Nationale, which contains about 2,000,000 volumes, 190,000 manuscripts, 5000 portfolios of engravings, and a great collection of coins and medals (see LIBRARIES), which originated in a small collection of books placed by Louis XI. in the Louvre. No city on this side of the Alps is richer than P. in fine-art collections, and among these the museums at the Louvre stand pre-eminent. The Palais des Beaux-Arts is used as an exhibition of art, manufactures, and architect-

ural models. The Hôtel Cluny, connected underground with the Palais des Thermes, in addition to its being in itself a most interesting monument of medieval art, contains curious relics of the arts and usages of the French people, from the earliest ages of their history to the Renaissance period. The Mint deserves notice for the perfection of its machinery. The Gobelins, or tapestry manufactory, may be included under the fine arts, as the productions of its looms are all manual, and demand great artistic skill. The Conservatoire des Arts et Métiers, in the Rue St. Martin, contains a great collection of models of machinery, and class-rooms for the instruction of workmen in all departments of applied science. The Palace of Industry, built in 1854 for the Universal Exhibition, now forms a permanent exhibition. The spacious building in which the Exhibition of 1878 took place was named Palace of the Trocadéro.

Among the parish churches of P. (upwards of 60 in number), the grandest and most interesting, in an historical point of view, is the cathedral of Notre-Dame, which stands on a site successively occupied by a pagan temple and a Christian basilica of the time of the Merovingian kings. The present building was constructed between the 12th and 15th centuries; and in its present state of restored magnificence, it may rank as one of the noblest specimens of Gothic architecture. St.-Germain-des-Prés, which is probably the most ancient church in P., was completed in 1163; St. Etienne du Mont and St. Germain l'Auxerrois, both ancient, are interesting—the former for its picturesque and quaint decorations, and for containing the tomb of St. Geneviève, the patron saint of P.; and the latter for its rich decorations and the frescoed portal, restored at the wish of Margaret of Valois. The Sainte Chapelle, built by St. Louis in 1245–1248, for the reception of the various relics which he had brought from the Holy Land, is one of the most remarkable buildings in Paris, profusely decorated in all parts with brilliantly colored materials. Its present beauty is entirely due to the restorations completed by the late emperor at a cost of £50,000. It was threatened by the Commune, but saved. Among modern churches are the Madeleine, built in imitation of a Greek temple, and gorgeous with gildings, frescoes, carvings, marbles, and statues; and the Pantheon, which was begun as a church, but converted by the Constituent Assembly of republican France into a temple dedicated to the great men of the nation—it was restored to the church by the late emperor, and re-dedicated to St. Geneviève; Notre-Dame de Lorette, erected in 1823, a flagrant specimen of the meretricious taste of the day; and St. Vincent de Paul, completed in 1844, somewhat less gaudy and more imposing in style; &c. Among the few Protestant churches, l'Oratoire is the largest and the best known.

P. abounds in theaters and places of amusement suited to the tastes and means of every class. The leading houses, as the Opéra, Théâtre Français—chiefly devoted to classical French drama—Odéon, Théâtre Italien, &c., receive a subvention from government, and all are under strict police supervision. The new opera-house, completed in 1875, is a wonderfully magnificent building, costing, exclusive of the site, £1,120,000. Cheap concerts, equestrian performances, and public balls, held in the open air in summer, supply a constant round of gaiety to the burgher and working classes at a moderate cost, and form a characteristic feature of P. life; while, in addition to the noble gardens of the various imperial palaces, the most densely-crowded parts of the city have public gardens, shaded by trees, and adorned with fountains and statues, which afford the means of health and recreation to the poor. Beyond the fortifications at the west of P. is the Bois de Boulogne, converted by the late emperor from a wood covered with stunted trees into one of the most beautiful gardens in Europe. That part of it which skirted the fortifications was cut up and destroyed during the siege, but since then it has been replanted, and is now as attractive to visitors as it has ever been.

P. has three large and twelve lesser cemeteries, of which the principal one is Père-la-Chaise, extending over 200 acres, and filled in every part with monuments erected to the memory of the countless number of celebrated persons who have been buried here. The Morgue is a building in which the bodies of unknown persons who have met with a violent death are placed, and which, if not claimed within three days, are buried at the public expense. The southern parts of the city are built over beds of limestone, rich in fossils, which have been so extensively quarried as to have become a mere network of vast caverns, which in some cases scarcely afford sufficient support to the houses above. These quarries were first converted in 1784 into catacombs, in which are deposited the bones of the dead, collected from the ancient cemeteries of Paris.

P. was surrounded, under Louis-Philippe, with fortifications extending 80 miles round, and costing £5,500,000 sterling, and, in addition to these, 16 detached forts have been erected at definite distances from one another. The Champ-de-Mars is a vast sandy plain near the Quai d'Orsay, on which reviews and other military displays and national festivals are held. Close to it stands the Ecole Militaire, founded in 1752, and used as barracks for in-

fantry and cavalry, of which it can accommodate 10,000 men, with space for 800 horses. The Hôtel des Invalides, founded in 1670 for disabled soldiers, is situated on the left bank of the river. The crypt of the church contains the sarcophagus, hewn from a huge block of Russian granite, in which lie the remains of Napoleon, deposited there in 1840.

P. is divided into 20 arrondissements. The prefect of the Seine is the chief of the municipal government, and is appointed by the government. There is a large municipal council, chosen by popular election. Each arrondissement has a maire and two assistant councillors. The prefect of police is at the head of the civic guard or gendarmes, the fire-brigade, and the sergents de ville or city police, who are armed with a sword. The cleaning, sewerage, and water supplies of P. are under the charge of the prefect. P. is now abundantly supplied with pure and wholesome water; since 1854, the length of vaulted sewers has been doubled, and now amounts to upwards of 250 miles. The same may be said in regard to the paving of the city, and the street lighting is effected by some 15,000 gas jets, and numerous electric lights. In 1818, public slaughter-houses, or abattoirs, were established at different suburbs, where alone animals are allowed to be slaughtered. Large cattle-markets are held near the licensed *Abattoirs* (q. v.). There are in the heart of the city numerous *halles*, or wholesale, and *marchés*, or retail markets. The principal of these is the Halles Centrales, near the church of St. Eustache, covering nearly 20 acres. Among the older markets are the Halle aux Vins, in which 500,000 casks of wine can be stowed, and the Marché aux Fleurs.

For an account of P., see *Le Nouveau Paris*, by Labedollière; Moriac's *Paris sous la Commune* (Paris, 1871); G. A. Sala's *Paris Herself again*; and the recent editions of Hachette's, Baedeker's, and Murray's guide-books. A great work, which was to include all the principal documents connected with the history of P., was commenced during the late empire, under the supervision of M. Haussman. Seven large quarto volumes had appeared when the work was interrupted by the events of 1871.

PARIS BASIN, the collective name of the beds of Eocene age, which rest in a hollow of the chalk in the district around Paris, where they occupy an oblong area measuring 180 miles in greatest length from north to south, and 90 miles in breadth from east to west. The different sections into which the series has been divided are given under Eocene (q. v.). The beds are chiefly remarkable for the rich harvest of organic remains which they supplied to Cuvier, and which led to the foundation of the modern science of Palæontology. The strata from which these were principally obtained consist of a series of white and green marls with subordinate beds of gypsum; they are largely developed at Montmartre, where the gypsum has been extensively quarried for the manufacture of plaster of Paris. The fossils consist of land and fluviatile shells, fresh-water fish and crocodiles, and the bones of birds and quadrupeds, besides a few land-plants, among which are some palms. The mammals, of which about 50 species have been described, belong to the order Pachydermata. The Paris Basin has for some time almost ceased to supply the remains of vertebrate animals.

PARIS, MATTHEW, the best Latin chronicler of the 13th c., was born in 1195, and in 1217 entered the Benedictine monastery of St. Albans. After the departure of Roger of Wendover, in 1235, P. was chosen to succeed him as annalist of the monastery. He discharged his functions with veracity and boldness, in consequence of which he greatly displeased some of his contemporaries. The principal external incident of his life was his voyage to Norway, whither he was invited by King Hakon, to repair the financial disorders in the Benedictine monastery of Holm. P. landed at Bergen, 10th July 1248, was courteously received by the Norwegian monarch, and settled the business about which he came in a satisfactory manner. After his return to England, he stood high in favor of Henry III., who used to converse with him in the most familiar manner, and from whose lips he derived not a little information that makes his *Chronicle* so valuable. He had also a wide circle of influential friends and acquaintances among the clergy from whom he obtained materials for his work. His death occurred in 1259. P. had a great reputation in his day for his virtues and abilities. He was considered a universal scholar, and is said by his laudatory biographers to have been versed in mathematics, poetry, oratory, divinity, history, painting, and architecture. One thing about him long kept his memory green in the hearts of his countrymen—he was a patriotic Englishman, and though a sincere Catholic (like all good men of his age), yet he loved his country better than the pope, and wrote so fiercely against the encroachments of the court of Rome in ecclesiastical matters, that his *Chronicle* became, in after times, a great favorite with the Reformers.

P.'s principal work is his *Historia Major*, which begins with the Norman Conquest, and extends to the year of the author's death. It was continued by William Rishanger, also a monk of St. Al-

bans, till the death of Henry III. in 1272. The first edition was published at London by Archbishop Parker, in 1571, and was reproduced at Zürich in 1606; later and more complete editions are those of London in 1640–1641, and in 1684. The only portion of the *Historia Major*, however, which is properly the work of P., is that extending from 1235 to 1259; the previous part being nearly a transcription from the *Flores Historiarum*, attributed to Roger of Wendover, whence some critics have supposed that P. is really the author of that work too. But this opinion is strenuously contested by the most recent editor of the *Flores Historiarum*, the Rev. H. O. Coxe (4 vols. 1841–1842). Translations both of P.'s *Chronicle* and that of Reger of Wendover have been published by Bohn in his Antiquarian Library. The British Museum, and the library of Corpus Christi College at Cambridge, contain manuscript abridgments of *Historia Major*, made by P. himself, and entitled *Chronica Majora Sancte Albani*; a second abridgment is known as the *Historia Minor*. Other works of P.'s are *Duorum Offarum Merciorum Regum Vita*; *Viginti trium Abbatum, S. Albani Vita*; and *Addimenta*, being explanatory additions to his *Historia Major*.

PA'RISH (Gr. *paroikia*, habitations, from *para*, near, and *oikemaî*, I dwell; Lat. *parochia*), the district assigned to a particular church, where the inhabitants of the district may attend at public worship, and receive the sacramental or other ministrations of the clergy. The name originally seems to have been interchangeable with *diocesis*, 'diocese,' and to have been applied to the district subject to the spiritual jurisdiction of a bishop; and, on the other hand, at a later period, *diocesis* was sometimes used to signify a parochial church or district. The distribution into parishes appears to be comparatively modern. Originally, all the clergy were (in the opinion of the Episcopalian churches) but coadjutors of the bishop, and served in his church, at which all the faithful assembled. At Alexandria, and afterwards at Rome, a number of minor churches were opened (called at Rome *tituli*), which were served by clergy, originally not permanently attached to them, but sent from the principal or bishop's church, but in progress of time fixed permanently in the charge. This, however, was not common; and we find churches, with clergy permanently attached, much earlier in rural districts than in cities. The institution does not appear to have become general till the 9th or 10th century. In England, the first legislation on the subject occurs in the laws of Edgar, about 970. The parochial division of districts seems in great measure to have followed the civil distribution into manors, or other feudal divisions of territory; and it is probable that it is to the same state of things we owe the practice of lay patronage, the priest officiating in a manorial church being chosen, with the bishop's consent, by the lord of the manor. The parochial revenue, however, by no means followed the same rules which now prevail.

At first, all ecclesiastical income, from whatever district, was carried into a common fund, which was placed at the disposal of the bishop, and was generally divided into four parts—for the bishop, for the clergy, for the poor, and for the church. By degrees, however, beginning first with the rural parishes, and ultimately extending to those of the cities, the parochial revenues were placed at the disposal of the parish clergy (subject to the same general threefold division, for the clergy, for the poor, and for the church); and in some places an abusive claim, which was early reprobated, arose upon the part of the lord of the manor to a portion of the revenue. Properly, a parish has but one church; but when the district is extensive, one or more minor (*succursal*) churches, sometimes called 'chapels of ease,' are permitted.

In the law of England, a parish is an important subdivision of the country, for purposes of local self-government, most of the local rates and taxes being confined within that area, and to a certain extent self-imposed by the parties who pay them. The origin of the division of England into parishes is not very clearly ascertained by the authorities. Some have asserted that the division had an ecclesiastical origin, and that a parish was merely a district sufficient for one priest to attend to. But others have asserted that parishes had a civil origin long anterior to ecclesiastical distinctions, advantage being merely taken to ingraft these on so convenient an existing subdivision of the country; and that a parish was a subdivision of the ancient hundred, known as a vill or town, and through its machinery the public taxes were anciently collected. Hobart fixes the date of the institution of civil parishes in 1179, and his account has been generally followed. Much difficulty has occasionally arisen in fixing the boundaries of parishes.

Blackstone says the boundaries of parishes were originally ascertained by those of manors, and that it very seldom happened that a manor extended itself over more parishes than one, though there were often many manors in one parish. Nevertheless, the boundaries of parishes are often intermixed, which Blackstone accounts for by the practice of the lords of adjoining manors obliging their tenants to appropriate their tithes towards the

officiating minister of the church, which was built for the whole. Even in the present day, these boundaries often give rise to litigation, and the courts have always decided the question according to the proof of custom. This custom is chiefly established by the ancient practice of perambulating the parish in Rogation-week in each year. See PERAMBULATION. There are some places as to which it is uncertain whether they are parishes or not, and hence it has been usual to call them reputed parishes. There are also places called extra-parochial places, which do not belong to any parish, such as forest and abbey lands. In these cases, the persons inhabiting were not subject to the usual parochial rates and taxes, and other incidents of parochial life. But in 1857, a statute was passed which put extra-parochial places upon a similar footing to parishes, by giving power to justices, and in some cases to the Poor-Law Board, to annex them to adjoining parishes, after which they are dealt with in much the same way as other places. One of the chief characteristics of a parish is, that there is a parish church, and an incumbent and churchwarden attached to it, and by this machinery the spiritual wants of the parishioners are attended to. These several parish churches, and the endowments connected therewith, belong in a certain sense to the nation, and the incumbents are members of the Established Church of England, and amenable to the discipline of the bishops and the spiritual courts.

The private patronage, or right of presenting a clergyman to an incumbency, is technically called an advowson, and is generally held by an individual as a saleable property, having a market value. The patron has an absolute right (quite irrespective of the wishes of the parishioners) to present a clerk or ordained priest of the church of England to a vacant benefice, and it is for the bishop to see to his qualifications. The bishop is the sole judge of these qualifications, and if he approves of them, the clerk or priest is instituted into the benefice, which ceremony completes his legal title to the fruits of the benefice. The incumbents of parish churches are called rectors, or vicars, or perpetual curates, the distinction being chiefly founded on the state of the tithes. When the benefice is full, then the freehold of the church vests in the rector or parson, and so does the churchyard; but he holds these only as a trustee for the use of the parishioners. There are certain duties which the incumbent of the parish church is bound by law to perform for the benefit of the parishioners. He is bound, as a general rule, to reside in the parish, so as to be ready to administer the rites of the church to them. See NON-RESIDENCE. The first duty of the incumbent is to perform public worship in the parish church every Sunday, according to the form prescribed by the Book of Common Prayer, which is part of the statute-law of England. He must adhere strictly to the forms and ceremonies, and even to the dress prescribed by the Book of Common Prayer and Canons. The incumbent is also bound to baptize the children of all the parishioners, and to administer the rite of the Lord's Supper to the parishioners not less than three times each year. The incumbent is also bound to allow the parishioners to be buried in the churchyard of the parish, if there is accommodation, and to read the burial-service at each interment. He is also bound to marry the parishioners on their tendering themselves, and complying with the marriage acts, within the parish church and during canonical hours, and it is said he is liable to an action of damages if he refuse.

In respect of burials and marriages, certain fees are frequently payable by custom; but unless such a custom exists, no fee is exigible for performance of these duties. In many cases, where one church had become insufficient for the increased population, the old parish has been subdivided under the Church Building Acts, the first of which was passed in 1818, into two or more ecclesiastical districts or parishes, for each of which a new church was built, and an incumbent appointed. The incumbents in these ecclesiastical parishes have generally been provided for by the incumbent of the mother-parish or by voluntary benefactors, and by the aid of pew-rents. But these ecclesiastical parishes, so far as the poor and other secular purposes are concerned, make no change on the old law. Another incident of the parish church is, that there must be churchwardens appointed annually, who are accordingly leading parochial officers, and whose duty is partly ecclesiastical and partly civil. Their civil duties consist chiefly in this, that they must join the overseers in many of the duties arising out of the management of the poor, and incidental duties imposed by statute. But their primary duty is to attend to the repair and good order of the fabric of the church. The common law requires that there should be two churchwardens, one of whom is appointed by the incumbent, and the other is chosen by the parishioners in vestry assembled, but sometimes this rule is varied by a local custom. This appointment and election take place in Easter-week of each year. In electing the people's churchwarden, there is often much local excitement, and it is common to poll the parish, all those who pay poor-rates being entitled to vote, the number of votes varying according to the rent, but no person having more than six votes. See CHURCHWARDENS; CHURCH RATES.

The next most important business connected with the parish is that which concerns the poor, the leading principle being, that each union is bound to pay the expense of relieving its own poor. See OVERSEERS; GUARDIAN; POOR.

Another important feature of the parish is, that all the highways within the parish must be kept in repair by the parish, i. e., by the inhabitants who are rated to the poor. For this purpose, the inhabitants of each parish, in vestry assembled, appoint each year a surveyor of highways, whose duty it is to see that the highways are kept in good repair; and he is authorized, by the General Highway Act, to levy a rate on all the property within the parish. The office of a surveyor of highways is, like those of churchwarden, overseer, and guardian, a compulsory and gratuitous office. When a highway is out of repair, the mode of enforcing the repair is by summoning the surveyor of highways before justices, to show cause why he has not repaired the road; and if the facts are not disputed, the justices either fine him, or order an indictment to be laid against the inhabitants of the parish. This indictment is tried, and the expense of it is defrayed out of the highway-rate, which is subsequently made. The highways of each parish being thus exclusively under the control of the ratepayers and their officers, it happened that great inequality prevailed in the standard of repairs which each parish set up for itself. This led to the late Highway District Acts, first passed in 1862, the object of which is to enable the justices of the peace of the district to combine several parishes into one district, and thus secure more uniformity in the repairs of the highways. A waywarden is now appointed to represent each parish at the Highway Board, instead of the old highway surveyor; but the expenses of maintaining the highways is still ultimately paid by the parish in which they are situated, the only change being, that the expenses are ordered to be incurred by the Highway Board, instead of the parochial officer.

The above duties in reference to the parish church, the poor, and the highways, are the leading duties attaching to the parish as a parish; but over and above these, many miscellaneous duties have been imposed on the parish officers, particularly on the overseers and churchwardens, which will be found specified under the head of OVERSEERS. In nearly all cases where the parish as a parish, is required to act, the mode in which it does so is by the machinery of a vestry. A vestry is a meeting of all the inhabitant householders rated to the poor. It is called by the churchwardens, and all questions are put to the vote. Any ratepayer who thinks the majority of those present do not represent the majority of the whole parishioners, is entitled to demand a poll. At these meetings, great excitement often prevails, especially when there existed church-rates. Wherever a parish improvement is found to be desirable, the vestry may meet and decide whether it is to be proceeded with, in which case they have powers of rating themselves for the expense. Such is the case as to the establishment of baths and wash-houses, watching, and lighting. Returns are made of all parish and local rates to parliament every year. The parish property, except the goods of the parish church, which are vested in the churchwardens, is vested in the overseers, who hold and manage the same, requiring the consent of the Poor-Law Board in order to sell it. For the elementary education system, and for school-boards as local authorities of districts (not necessarily parishes), see NATIONAL EDUCATION.

In Scotland, the division into parishes has existed from the most ancient times, and is recognized for certain civil purposes relative to taxation and otherwise, as well as for purposes purely ecclesiastical. The Court of Sessions, acting as the Commission of Teinds, may unite two or more parishes into one; or may divide a parish, or disjoin part of it, with consent of the heritors (or landholders) of a major part of the valuation; or apart from their consent, if it be shown that there is within the disjoined part a sufficient place of worship, and if the Titulars of Teinds (q. v.), or others who have to pay no less than three-fourths of the additional stipend, do not object. By Act. 7 and 8 Vict. c. 44, any district where there is an endowed church may be erected into a parish *quoad sacra*, for such purposes as are purely ecclesiastical. Endowed Gaelic congregations in the large towns of the Lowlands may similarly be erected into parishes *quoad sacra*.

The principal application of the parochial division for civil purposes relates to the administration of the poor-law. Under the old system the administrators of the poor law were the kirk-session in county parishes, and the magistrates, or certain managers selected by them, in burghal parishes. The Act 8 and 9 Vict. c. 83, which remodelled the poor-law of Scotland retained the old administrative body so long as there was no assessment; but, on a parish being assessed, substituted for it a new one, consisting in rural parishes of the owners of heritable property of £20 yearly value, of the magistrates of any royal burgh within the bounds, of the kirk-session, a certain number of members chosen by the persons assessed; and in burghal parishes of members, not exceeding 30, chosen by the persons assessed, four members named by the magistrates, and not above four by the kirk-session or ses-

sions. The Board of Supervision may unite two or more parishes into a combination for poor-law purposes. There is not the same extensive machinery for parochial self-government that exists in England.

The burden of supporting the fabric of the church falls on the heritors, and there are no churchwardens. Highways are not repairable by the parish, and there are no elections of surveyors or way-wardens. The meeting of the inhabitants in vestry, which so often takes place in England, is unknown in Scotland, and hence the ratepayers do not interest themselves so much in local affairs. Many of the duties which in England are discharged by parochial officers, are in Scotland discharged by the sheriff-clerk, a county-officer. The system of having a Parish School (q. v.) in every parish (a system extended by the Education Act of 1872) has long prevailed in Scotland, though unknown in England till the year 1870.

PARISH CLERK, in England, is an officer of the parish of some importance, his duty being to lead the responses during the reading of the service in the parish church. He is appointed by the parson, unless some other custom of a peculiar kind exists in the parish. He must be 20 years of age, and has his office for life, but is removable by the parson for sufficient cause. By the statute 7 and 8 Vict. c. 59, a person in holy orders may be elected a parish clerk. Under some of the Church Building Acts governing the new churches built in populous parishes, he is annually appointed by the minister. The salary of the parish clerk is paid out of the church-rate.

PARISH SCHOOL. In England, prior to the recent Education Act, there was no such thing as a parish school—that is, a school existing for the benefit of the parishioners, endowed by the state, or supported by taxes on the parishioners. Every school beyond charity schools was more or less voluntary in its character, and endowed, if at all, by private benefactors. In Scotland, however, it was essential that in every parish there should be a parish school, for a statute of 1696 made it compulsory on the heritors—i. e., the chief proprietors—to provide a school-house, and to fix a salary for the teacher. If the heritors neglected to supply a school-house, the presbytery was empowered to order one at the expense of the heritors. The schoolmaster's salary was fixed according to a certain proportion, half of the rate or cess being paid by the landlord, and half by the tenant.

In 1803, a statute was passed to regulate the salaries, and to give a right to the schoolmaster to have a house and garden. The office was further regulated by a later act, 24 and 25 Vict. c. 107. The salary was fixed to be from £35 to £70 per annum, to be varied and fixed by the heritors and minister of the parish, in the case of future vacancies. The qualification of the schoolmaster consisted in passing an examination conducted by the examiners of parochial schoolmasters, who were professors of the universities, who made regulations as to the time and mode of examination. For this purpose, Scotland was divided into four districts, each in connection with one of the Scotch universities. When examined, the person obtained a certificate of fitness from these examiners. The schoolmaster, who had formerly, before admission to office, been required to sign the Confession of Faith and the formula of the Church of Scotland, and to profess that he would submit to its government and its discipline, had by this act merely to make a declaration that he would not, in his office, endeavor, directly or indirectly, to teach or inculcate opinions opposed to the divine authority of the Holy Scriptures, or to the doctrines contained in the Shorter Catechism, agreed upon by the Assembly of Divines at Westminster, and approved by the General Assembly of the Church of Scotland, and that he would not exercise the functions of his office to the prejudice or subversion of the Church of Scotland as by law established. In case of misconduct, the Presbytery might complain to the Secretary of State, who would institute a commission to inquire and report, and to censure, suspend, or deprive such schoolmaster accordingly. The sheriff of the county was made the sole judge of charges of immorality, or cruel or improper treatment of the scholars, offences formerly cognizable by the Presbytery; and the heritors and minister might permit or require him to resign, and allow him a retiring allowance. Notwithstanding all these improvements, however, it continued to be apparent that the system of parish schools, however well adapted to Scotland at the Revolution, had fallen behind the requirements of the country, when the population had tripled, and large manufacturing villages and towns had sprung up in rural districts. But for denominational and other schools, vast numbers of children would have been left without the rudiments of education.

By the Education (Scotland) Act, 35 and 37 Vict. c. 62 (1872), the parish schools were placed under the management of the School Board of each parish, the jurisdiction of heritors, ministers, and church courts were abolished, and every school under the management of the School Board was declared to be equally a parish school. Teachers in office before the act are not to be

prejudiced by its provisions; those whom the School Boards appoint are to have such salaries assigned them as the Boards think fit, and to hold office at pleasure of the Board.

PARK (Fr. *parc*), a term still employed in some parts of Britain in its original sense, to denote a field or enclosure, but more generally applied to the enclosed grounds around a mansion, designated in Scotland by another term of French origin, *policey*. The park, in this sense, includes not only the lawn, but all that is devoted to the growth of timber, pasturage for deer, sheep, cattle, &c., in connection with the mansion, wherever pleasure-walks or drives extend, or the purpose of enjoyment prevails over that of economical use. *Public parks* are those in the vicinity of towns and cities, open to the public, and intended for their benefit. An increase of public parks is a pleasing feature of the present age, and not a few towns enjoy parks recently bestowed by wealthy persons somehow connected with them.

PARK, MUNGO, a celebrated African traveler, was the son of a Scottish farmer, and was born 10th September 1771 at Fowlishiels near Selkirk. He studied medicine in Edinburgh, and afterwards went to London, where he obtained the situation of assistant-surgeon in a vessel bound for the East Indies. When he returned in 1793, the *African Association* of London had received intelligence of the death of Major Houghton, who had undertaken a journey to Africa at their expense. P. offered himself for a similar undertaking, was accepted, and sailed from England 22d May 1795. He spent some months at the English factory of Pisania on the Gambia in making preparations for his further travels, and in learning the Mandingo language.

Leaving Pisania on the 2d of December he traveled eastward; but when he had nearly reached the place where Houghton lost his life, he fell into the hands of a Moorish king, who imprisoned him, and treated him so roughly, that P. seized an opportunity of escaping (1st July 1796). In the third week of his flight, he reached the Niger, the great object of his search, at Sego (in the kingdom of Bambarra), and followed its course downwards as far as Silla; but meeting with hindrances that compelled him to retrace his steps, he pursued his way westwards along its banks to Bammakoe, and then crossed a mountainous country till he came to Kamalia, in the kingdom of Mandingo (14th September), where he was taken ill, and lay for seven months. A slave-trader at last conveyed him again to the English factory on the Gambia, where he arrived 10th June 1797, after an absence of nineteen months. He published an account of his travels after his return to Britain, under the title of *Travels in the Interior of Africa* (Lond. 1799), a work which at once acquired a high popularity. He now married and settled as a surgeon at Peebles, where, however, he did not acquire an extensive practice; so that, in 1805, he undertook another journey to Africa, at the expense of the government. When he started from Pisania, he had a company of 45, of whom 35 were European soldiers; but when he reached the Niger in August, his attendants were reduced to seven, so fatal is the rainy season in those regions to Europeans. From Sansanding on the Niger, in the kingdom of Bambarra, he sent back his journals and letters in November 1805 to Gambia; and built a boat, in which he embarked with four European companions, and reached the kingdom of Houssa, where he and they are believed to have been murdered by the natives, or drowned as they attempted to sail through a narrow channel of the river.

The fragments of information and other evidence picked up among the natives by Clapperton and Lander (q. v.), strongly confirm this view of the fate of P. and his companions. An account of P.'s second journey was published at London in 1815. P.'s narratives are of no inconsiderable value, particularly for the light which they throw upon the social and domestic life of the negroes, and on the botany and meteorology of the regions through which he passed; but he was unfortunately cut off before he had determined the grand object of his explorations—the discovery of the course of the Niger.

PARK OF ARTILLERY is the whole train of great guns with equipment, ammunition, horses, and gunners for an army in the field. It is placed in a situation whence rapid access can be had to the line of the army in any part; and at the same time where the divisions of the force can easily mass for its protection. The horses of the park are picketed in lines in its rear.

PA'RKA, the name given by Fleming to a fossil from the Old Red Sandstone, about which there has been considerable difference of opinion. The quarrymen call them 'berries,' from their resemblance to a compressed raspberry. They were compared by Fleming to the panicles of a *Juncus*, or the globose head of a *Sparganium*. Lyell thinks they resemble the egg-cases of a *Natica*, while Mantel suggested that they were the eggs of a batrachian. The opinion now most generally entertained is that they are the eggs of the *Pterygotus*.

PARKER, a family of distinction in the annals of the British navy. The founder of the family was **SIR HUGH PARKER**, an

alderman of London, who received a baronetcy in 1681.—His grand-nephew, SIR HYDE PARKER, commanded the British fleet in the action off the Dogger Bank, 5th August 1781, in which three Dutch ships were destroyed, and the rest of the Dutch fleet compelled to retreat into harbor. In 1783, he was appointed to the command of the British fleet in the East Indies; but the ship in which he sailed thither was lost, with all on board.—His second son, SIR HYDE PARKER, distinguished himself in the American war; blockaded the Dutch harbors with a small squadron in 1782; commanded the British fleet in the West Indies in 1795; and in 1801 was appointed to the chief command of the fleet which was sent to the Baltic to act against the armed coalition of the three northern states of Russia, Sweden, and Denmark. He had no share in the battle of Copenhagen, in which Nelson engaged contrary to his orders; but by his appearance before Carlsrona, he compelled the neutrality of Sweden; and he was on the point of sailing for Cronstadt, when the news of Paul's death put an end to hostilities.—His kinsman, SIR WILLIAM PARKER, was also a British admiral of high repute for his skill and bravery, and contributed to some of the great victories of the close of last century.—SIR PETER PARKER, who was born in 1716, and died in 1811, with the rank of admiral of the fleet, served with distinction during the Seven Years' and the American wars; and in 1783 brought the French admiral, De Grasse, a prisoner to England, for which he received a baronetcy.—SIR WILLIAM PARKER, born in 1781, commanded the frigate *Amazon* in 1806, and took, after a hard fought battle, the French frigate *La Belle Poule*, belonging to the squadron of Admiral Lincolns; and in 1809 captured the citadel of Ferrol.

In 1841, he succeeded to Admiral Elliot in the command of the fleet in the Chinese seas during the first Chinese war. He took possession of Chusan, Ningpo, and Shapn; forced the entrance of the Yang-tse-kiang; and arrived under the walls of Nanking, where the treaty of peace was agreed upon. For these services, he received a baronetcy in 1844. He was afterwards appointed to the command of the fleet in the Mediterranean, and exerted himself, although in vain, to mediate between the Neapolitan government and the insurgent Sicilians. In autumn 1849, he sailed to the Dardanelles, at the request of Sir Stratford Canning (now Lord Stratford de Redcliffe), to support the Porte against the threatening demands of Austria and Russia concerning political fugitives; and in January 1850 he compelled the Greek government, by a blockade of their ports, to comply with the demands of Britain. Named in 1851 Admiral of the Blue, he resigned the command of the Mediterranean fleet to Admiral Dundas, was created Admiral of the White in 1853, Admiral of the Red in 1858, and Rear-admiral of the United Kingdom in 1862. He died in 1866.

PARKER, MATTHEW, the second Protestant Archbishop of Canterbury, was born at Norwich, August 6, 1504, studied at Corpus Christi College, Cambridge, and was ordained a priest in 1527. At the university, he was a distinguished student, especially of the Scriptures and of the history of the church, even to antiquarian minuteness; yet, in spite of his strong leaning to the past, he was from an early period favorably disposed towards the doctrines of the Reformation, and lived in close intimacy with some of the more ardent reformers. In 1538, he was appointed chaplain to Queen Anne Boleyn, who thought very highly of him, and not long before her death, exhorted her daughter Elizabeth to avail herself of P.'s wise and pious counsel. In 1535, he obtained the deanery of the monastic college of Stoke-Clare in Suffolk—*Roman Catholicism*, it must not be forgotten, being still the professed religion of the land, for Henry had not yet formally broken with the pope—and here the studious clerk continued his pursuit of classical and ecclesiastical literature, and at the same time set himself to correct the prevailing decay of morals and learning in the church, by founding a school in the locality for the purpose of instructing the youth in the study of grammar and humanity. Here, too, he appears for the first time to have definitely sided with the reforming party in the church and state, the sermons which he preached containing bold attacks on different Catholic tenets and practices.

In 1538, P. took the degree of D.D.; and in 1544, after some minor changes, became master of Corpus Christi College, Cambridge, which he ruled admirably. Three years later, he married Margaret Harlstone, the daughter of a Norfolkshire gentleman. It was probably about this time that he drew up his defence of the marriage of priests, entitled *De Conjugio Sacerdotum*. In 1552, he was presented by King Edward VI. to the canonry and prebend of Covingham, in the church of Lincoln. On the accession of Queen Mary, he refused to conform to the re-established order of things, and was (like many others of the new school of divines) deprived of his preferments, and even obliged to conceal himself. It does not appear, however, that he was eagerly sought after by the emissaries of Mary; for he was no fanatic or iconoclast, but, on the contrary, though sincerely attached to the common Protestant doctrines, very unwilling to disturb the framework of the

church. P. spent at least some portion of his compulsory seclusion from public life in the enlargement of his *De Conjugio Sacerdotum*, and in translating the Psalms into English meter. The death of Mary, and the accession of Elizabeth, called him from that learned retirement of which he seems to have been sincerely fond. Sir Nicholas Bacon, now Lord-keeper of the Great Seal, and Sir William Cecil, Secretary of State, both old Cambridge friends, knew what a solid and sure judgment, what a moderate and equable spirit, and above all, what a thorough faculty for business, ecclesiastical and secular, P. had, and by their recommendation he was appointed, by the queen, archbishop of Canterbury. The consecration took place in Lambeth chapel, December 17, 1559.

'The subsequent history of Archbishop Parker,' it has been justly remarked, 'is that of the Church of England.' The difficulties that beset him were very great. Elizabeth herself was much addicted to various 'popish' practices, such as the idolatrous use of images, and was strongly, we might even say, violently, in favor of the celibacy of the clergy. She went so far as to insult P.'s wife on one occasion. But his greatest anxiety was in regard to the spirit of sectarian dissension within the bosom of the church itself. Already the germs of *puritanism* were beginning to spring up, and there can be no doubt that their growth was fostered by the despotic caprices of the queen. P. himself was manifestly convinced that if ever Protestantism was to be firmly established in the land at all, some definite ecclesiastical forms and methods must be sanctioned, to secure the triumph of order over anarchy, and so he vigorously set about the repression of what he thought a mutinous individualism incompatible with a catholic spirit. That he always acted wisely or well, cannot be affirmed; he was forced, by virtue of his very attitude, into intolerant and inquisitorial courses, and as he grew older, he grew harsher, the conservative spirit increasing with his years. To forbid 'prophecysings,' or meetings for religious discourse, was something very like persecution, though probably enough something very like treason to the church was talked in these pious conventicles. Fuller (who must have his pun, however bad) says of him: 'He was a Parker indeed, careful to keep the fences.' Yet it must not be forgotten that it is to P. we owe the *Bishops' Bible*, undertaken at his request, carried on under his inspection, and published at his expense in 1568. He had also the principal share in drawing up the *Book of Common Prayer*, for which his skill in ancient liturgies peculiarly fitted him, and which strikingly bears the impress of his broad, moderate, and unsectarian intellect. It was under his presidency, too, that the *Thirty-nine Articles* were finally reviewed and subscribed by the clergy (1562). P. died May 17, 1575.

Among other literary performances, P. published an old *Saxon Homily on the Sacrament*, by Elfric of St. Albans, to prove that Transubstantiation was not the doctrine of the ancient English church; edited the histories of Matthew of Westminster and Matthew Paris (q. v.); and superintended the publication of a most valuable work, *De Antiquitate Britannicæ Ecclesiæ*, probably printed at Lambeth in 1572, where the archbishop, we are told, had an establishment of printers, engravers, and illuminators. He also founded the 'Society of Antiquaries,' and was its first president; endowed the university of Cambridge, and particularly his own college, with many fellowships and scholarships, and with a magnificent collection of MSS. relating to the civil and ecclesiastical condition of England, and belonging to nine different centuries (from the 8th to the 16th). Of this collection, Fuller said that it was 'the sun of English antiquity before it was eclipsed by that of Sir Robert Cotton.'

PARKER, THEODORE, an American clergyman and scholar, was born at Lexington, Massachusetts, August 24, 1810. His grandfather was captain of a militia company at the battle of Lexington, his father a farmer and mechanic, and his own boyhood was spent at the district school, on the farm, and in the workshop. At the age of 17, he taught a school, and earned money to enter Harvard College in 1830. During his collegiate course, he supported himself by teaching private classes and schools, and studied metaphysics, theology, Anglo-Saxon, Syriac, Arabic, Danish, Swedish, German, French, Spanish, and modern Greek. Entering the divinity class, at the end of his collegiate course, he commenced to preach in 1836, was an editor of the *Scriptural Interpreter*, and settled as Unitarian minister at West Roxbury in 1837.

The naturalistic or rationalistic views which separated him from the more conservative portion of the Unitarians, first attracted wide notice, in consequence of an ordination sermon, in 1841, on *The Transient and Permanent in Christianity*. The contest which arose on the anti-supernaturalism of this discourse, led him to further develop his theological views in five lectures, delivered in Boston, and published (1841) under the title of *A Discourse of Matters Pertaining to Religion*, which was followed by *Sermons for the Times*. Failing health induced him to make an extended tour in Europe. In 1845, he returned to Boston, preached to large

audiences at the Melodeon, and wrote for the *Dial*, *Christian Register*, *Christian Examiner*, and *Massachusetts Quarterly*. He became also a popular lecturer, and was active and earnest in opposition to slavery, the Mexican war, and the Fugitive Slave Law, for resisting which, by more than words, he was indicted. In the midst of his work, he was attacked, in 1859, with bleeding from the lungs, and made a voyage to Mexico, where he wrote his *Experience as a Minister*, whence he sailed to Italy, where he died at Florence, May 10, 1860. His works, consisting chiefly of miscellanies, lectures and sermons, have been collected and published in America and England, in which his peculiar views in theology and politics are sustained with great force of logic and felicity of illustration. His learning was equal to his energy and philanthropy, and his influence was also great. His library of 13,000 volumes he bequeathed to the Boston Free Library. See P.'s *Life and Correspondence*, by Weiss (1864).

PA'RKESINE, the name given to a substance introduced for manufacturing purposes by Mr. Parkes of Birmingham. In that town, where so many kinds of small objects are made in countless thousands daily, it is of great importance to get hold of a cheap material which will in some measure partake of the properties of ivory, bone, horn, tortoiseshell, hardwood, India-rubber, or other natural substances. There are a number of artificial compositions which to some extent do this, and Parkesine is one of these. It is said to be a mixture of pyroxyline (gun-cotton) and oil, hardened with chloride of sulphur. The pyroxyline is made from any vegetable fibre, as cotton and flax waste, or rags. According to another account, it is composed of castor oil, collodion, and wood spirit. For large and cheap objects other materials and solvents can be used, to which saw-dust, cork-dust, or pigments may be largely added.

P. does not soften, like gutta-percha, by heat; it may be made either opaque or transparent, plain or colored; it will make a very strong joint after fracture; it will resist most of the common acids. In its hard form, the surface can be so treated as to imitate marble, tortoiseshell, amber, or malachite. It may be moulded, pressed, turned, sawn, planed, carved, rolled, engraved, inlaid, or polished, according to the consistency given to it in the course of manufacture; or it may be made thin enough to use, when melted, as a varnish or waterproofing. It may be made into knife-handles, combs, brush-backs, shoe-soles, umbrella handles, buttons, tubes, galvanic-battery cells, waterproof fabrics, surgical implements, and telegraphic insulators.

PARKHURST, JOHN, an English Biblical scholar, the second son of John Parkhurst, Esq., of Catesby, in Northamptonshire, was born in June 1728, educated at Rugby and at Clare Hall, Cambridge, where he took his degree of M.A. in 1752, and in 1753 published *A serious and Friendly Address to the Rev. John Wesley, in Relation to a Principal Doctrine advanced and maintained by him and his Assistants*. The doctrine assailed in P.'s pamphlet was the favorite Wesleyan doctrine of 'Assurance.' In 1762 appeared his principal work—indeed the only thing that has preserved his name—*A Hebrew and English Lexicon, without Points, adapted to the use of Learners*. P. kept mending this Hebrew lexicon all his life. It was a very creditable performance for its time, and long continued to be the standard work on the subject among biblical students in this country; but it is disfigured by its fanciful etymologies, partly the result of his having (like many other divines of his time) adopted the irrational and presumptuous theories of Hutchinson (q. v.), and is now entirely superseded by the works of Gensenius, Ewald, and other critical scholars. P. also wrote a treatise (1787) against Dr. Priestly, to prove the divinity and pre-existence of Jesus Christ. He died at Epsom, in Surrey, March 21, 1797.

PARKINSONIA, a genus of plants of the natural order *Leguminosæ*, sub-order *Cesalpiniæ*.—*P. aculeata* is a West Indian shrub or small tree, which, when in flower, is one of the most splendid objects in the vegetable kingdom. It has pinnated leaves, with winged leaf-stalk, and large yellow flowers spotted with red. It is furnished with strong spines, and is often used for hedges whence it is called the Barbadoes Flower Fence. It is now common in India. The bark yields a beautiful white fibre, which, however, is not very strong; but it has been suggested that it might be found suitable for paper-making.

PA'RDLEY, in Military Language, is an oral conference with the enemy. It takes place under a flag of truce, and usually at some spot—for the time neutral—between the lines of the two armies.

PARLIAMENT (Fr. *parlement*, from *parler*, to talk), the supreme legislature of the United Kingdom of Great Britain and Ireland. The word was first applied, according to Blackstone, to general assemblies of the states under Louis VII. in France about the middle of the 12th c.; but in that country it came eventually to be the designation of a body which performed cer-

tain administrative functions, but whose principal duties were those of a court of justice.

The origin of the Parliament of England has been traced to the Saxon great councils of the nation called 'Witten-gemote,' or meeting of wise men. These had, however, little in common with the parliaments of a later date: among other points of difference, they had a right to assemble when they pleased without royal warrant. Even under the Norman kings, the Great Council formed a judicial and ministerial as well as a legislative body, and it was only gradually that the judicial functions were transferred to courts of justice, and the ministerial to the privy council—a remnant of the judicial powers of parliament being still preserved in the appellate jurisdiction of the House of Lords. Under the Norman kings, the council of the sovereign consisted of the tenants-in-chief of the crown, who held their lands *per baroniam*, lay and ecclesiastic. It was the principle of the feudal system that every tenant should attend the court of his immediate superior; and he who held *per baroniam*, having no superior but the crown, was bound to attend his sovereign in the Great Council or Parliament. In the charter of King John, we for the first time trace the germ of a distinction between the peerage and the lesser nobility, the archbishops, bishops, abbots, earls, and greater barons being required to attend by a writ addressed to each, and the other tenants-in-chief by a general summons by the sheriffs and bailiffs. Baronial tenure originally made a man a baron or lord of parliament.

. When the offices or titles of Earl, Marquis, or Duke were bestowed on a baron, they were conferred by royal writ or patent, and at length barony came also to be conferred by writ instead of by tenure. During the 13th c., the smaller barons were allowed, instead of personally attending the national council, to appear by representatives; but the principle of representation seems first to have been reduced to a system when permission was also given to the municipalities, which, as corporations, were chief tenants of the crown, to appear by representatives. It is not quite clear when the division of parliament into two Houses took place; but when the representatives of the minor barons were joined by those of the municipalities, the term Commons was applied to both. The Lower House was early allowed to deal exclusively with questions of supply; and seems, in the reign of Richard II., to have established the right to assign the supplies to their proper uses. As the Commons became more powerful, they came to insist on the crown redressing their grievances before they would vote the supplies. The influence of parliament was on the increase during the Tudor period, while the reign of the Stewarts was characterized by a struggle for supremacy between the parliament and the crown, each striving to acquire the control of the military force of the country. The powers of the different estates came to be more sharply defined at the Revolution of 1688. Nineteen years later, on the Union with Scotland, the parliament of England was merged into that of Great Britain.

In its early history, prior to the War of Independence, the Parliament of Scotland had probably not been very unlike that of England; it assembled without warrant, and consisted of bishops, earls, priors, abbots, and barons. At the close of the 13th c., the constitutional history of Scotland diverges from that of England. The addition of the burghs to the national council seems to date from the beginning of the 14th c., but it was not till much later that the lesser barons began to be exempted from attendance. The first act excusing them belongs to the reign of James I., and allows them to choose representatives called *Speakers*, two for each county, excepting some small counties, which were to have but one, the expenses of the representatives being defrayed by the constituency. The Scottish Parliament was never, like the English, divided into two Houses; all sat in one hall, and though it consisted of three estates, a general numerical majority of members was considered sufficient to carry a measure. The greater part of the business was transacted by the Lords of the Articles, a committee named by the parliament at the beginning of each session, to consider what measures should be passed; and whatever they recommended was generally passed without discussion. It was never held indispensable that the parliament should be summoned by the crown, and it has even been thought that the royal assent to the measures carried was not absolutely essential. The parliament which carried the Reformation had no royal sanction. The Union was adjusted by commissioners for each country selected by the crown, and passed first, after strong and protracted opposition, in Scotland, and afterwards more easily in England.

By the act of union with Ireland in 1800 (Act 39 and 40 Geo. III. c. 67), the Irish Parliament was united with that of Great Britain as the Parliament of the United Kingdom of Great Britain and Ireland. The Parliament of Ireland had been originally formed on the model of that of England about the close of the 13th c., but it was merely the very small portion of Ireland occupied by the English settlers that was represented, which, as

late as the time of Henry VII., hardly extended beyond the counties of Dublin, Louth, Kildare, and Meath, and constituted what was called the Pale. It was only for the last few years of its existence that the Irish Parliament was a supreme legislature; the English Parliament having, down to 1783, had power to legislate for Ireland. By one of the provisions of Poyning's Act, passed in 1495, no legislative proposals could be made to the Irish Parliament until they had received the sanction of the king and council in England. Act 23 Geo. III. c. 28 gave the Irish Parliament exclusive authority to legislate for Ireland, and the abuse of this power so obstructed the machinery of government, as to render the Union of 1800 matter of necessity.

The power of parliament is, according to Sir Edward Coke, so transcendent and absolute, that it cannot be confined either for persons or causes within any bounds. All remedies which transcend the ordinary courts of law are within its reach. It can alter the succession to the throne, the constitution of the kingdom, and the constitution of parliament itself. It has its own law, to be learned from the rolls and records of parliament, and by precedents and experience. One of the most thoroughly established maxims of this law is, that whatever question arises concerning either House of Parliament ought to be discussed and adjudged there, and not elsewhere. The House of Lords will not allow the Commons to interfere in a question regarding an election of a Scotch or Irish peer; the Commons will not allow the Lords to judge of the validity of the election of a member of their House, nor will either House permit courts of law to examine such cases.

The authority of parliament extends to British colonies and foreign possessions. In the ordinary course of government, however, parliament does not make laws for the colonies. For some the Queen in Council legislates; others have legislatures of their own, which propound laws for their internal government, subject to the approbation of the Queen in Council; but these may be repealed and amended by parliament.

The constituent parts of parliament are the sovereign, the House of Lords, and the House of Commons. In the sovereign is vested the whole executive power; the crown is also the fountain of justice, from whence the whole judicial authority flows. To the crown is intrusted the permanent duty of government, to be fulfilled in accordance with the law of the realm, and by the advice of ministers responsible to parliament. The sovereign is also invested with the character of the representation of the majesty of the state. The sovereign's share in the legislature includes the summoning, proroguing, and dissolving of parliament. Parliament can only assemble by act of the sovereign; in but two instances have the Lords and Commons met of their own authority—viz., previously to the Restoration of Charles II., and at the Convention of Parliament summoned at the Revolution of 1688; and in both instances it was considered necessary afterwards to pass an act declaring the parliament to be a legal one. Though the queen may determine the period for assembling parliament, her prerogative is restrained within certain limits. She is bound by statute (16 Chas. II. c. 1; and 6 and 7 Will. and Mary, c. 2) to issue writs within three years after the determination of a parliament; and the practice of voting money for the public service by annual enactments, renders it compulsory for the sovereign to meet parliament every year. Act 43 Geo. III. c. 90 provides that the sovereign shall assemble parliament within fourteen days, whenever the militia shall be drawn out and embodied in case of apprehended invasion and rebellion; and a similar proviso is inserted in Act 15 and 16 Vict. c. 50, in case the present militia force should be raised to 120,000 men, and embodied. The royal assent is necessary before any measure can pass into law.

The crown, as the executive power, is charged with the management of the revenues of the state, and with all payments for the public service; it is therefore the crown that makes known to the Commons the pecuniary necessities of the government, without which no supplies can be granted. The sovereign's prerogative also includes the sending and receiving of ambassadors, entering into treaty with foreign powers, and declaring war or peace. All the kings and queens since the Revolution have taken an oath at their coronation 'to govern according to the statutes in parliament agreed on, and the laws and customs of the same.' The sovereign is further bound to an adherence to the Protestant faith, and the maintenance of the Protestant religion as established by law. By the Bill of Rights (1 Will. and Mary c. 2, s. 6), and the Act of Settlement (12 and 13 Will. III. c. 2, s. 2) a person professing the popish religion, or marrying a papist, is incapable of inheriting the crown, and the people are absolved from their allegiance. This exclusion is further confirmed by the Act of Union with Scotland; and in addition to the coronation oath, every king or queen is required to take the declaration against the doctrines of the Roman Catholic Church prescribed by 20 Chas. II. c. 2, either on the throne in the House of Lords in the presence of both Houses, at the first meeting of the first parliament after the accession, or at the coronation, whichever event shall first happen. The sovereign is bound by similar sanctions to

maintain the Protestant religion and Presbyterian church government in Scotland.

The province of the Houses of Parliament is to legislate with the crown, to provide supplies, to exercise a supervision over the ministers of the crown and all other functionaries, and to advise the sovereign on matters of public moment. The Upper House, from its hereditary and aristocratic character, is a check on the popular branch of the legislature and on hasty legislation.

The House of Lords may originate legislative measures of all kinds, except money-bills. Acts of grace and bills affecting the rights of peers must originate in this House. In its judicial capacity, defined by the Appellate Jurisdiction Act, 1876, it forms a court of final appeal from Her Majesty's Court of Appeal in England, from the Court of Session, Scotland, and the superior courts of law and equity of Ireland. It has a judicature in claims of peerage and offices of honor under reference from the crown. Since the union with Scotland and Ireland, it has had the power of deciding disputed elections of representative peers. It tries offenders impeached by the House of Commons, and members of its own body on indictment found by a grand jury. The House of Lords is composed of lords spiritual and temporal. According to a declaration of the House in 1672, the lords spiritual are only lords of parliament, and not peers. They consist of 2 archbishops and 24 bishops for England, who are said to have seats in virtue of their temporal baronies. (By the act of 1869, the Irish Church, which formerly sent 4 bishops, is no longer represented.) The Bishop of Sodor and Man has no seat in parliament. On Manchester being made a see in 1847, it was arranged that one other bishop should have no seat, by a rotation not including the bishops of London, Durham, and Winchester, so as not to increase the number of the lords spiritual. The same rule was applied on the foundation of the new sees, St. Albans, Truro, and Liverpool. The lords temporal consist of—1. The peers of England, of Great Britain, and of the United Kingdom, of whom there were, in 1881, 6 princes of the royal blood, 21 dukes, 20 marquises, 181 earls, 25 viscounts, and 254 barons.

The peers of the United Kingdom may be increased without limit by new creations at the pleasure of the sovereign. 2. Sixteen representatives chosen from their own body by the peers of Scotland for each parliament. As no provision was made at the Union for any subsequent creation of Scottish peers, the peerage of Scotland consists exclusively of the descendants of peers existing before the Union. By order of the House of Lords, an authentic list of the Scottish peers was entered on the roll of peers on 12th February 1708, to which all claims since established have been added; and in order to prevent the assumption of dormant and extinct peerages by persons not having right to them, statute 10 and 11 Vict. c. 52, provides that no title standing in the roll, in right of which no vote has been given since 1800, shall be called over at an election without an order of the House of Lords. 3. Twenty-eight representatives of the Irish peerage, elected for life. Most peerages are still hereditary. Life peerages were in early times not unknown to the constitution; but in 1856, Her Majesty having created Lord Wensleydale a peer for life, the House of Lords decided he could not sit and vote. But in 1876, peers to sit as members of the House while they held the office of Lords of Appeal in Ordinary—i.e., for judicial business, but on ceasing to act as judges to be peers no longer—were created by statute. The House has also power to call to its assistance in legal and constitutional questions the judges of the Supreme Court of Judicature of all the four divisions, who advise what should be done. The House has power also to sit for judicial business during the prorogation of parliament. The votes of spiritual and temporal lords are intermixed, and the joint majority determine every question; but they sit apart on separate benches—the place assigned to the lords spiritual being the upper part of the House on the right hand of the throne.

A lord may, by license from the sovereign, appoint another lord as his proxy to vote for him in his absence; but a lord spiritual can only be proxy for a lord spiritual, and a lord temporal for a lord temporal, and no member of the House can hold more than two proxies at the same time. Proxies cannot vote in judicial questions or in committees of the whole House. There are other rules and restrictions incident to the right of vote by proxy; a Lords' committee in 1867 reported that the practice of using proxies should be discontinued, but no alteration in the rules was agreed to. Peerages are lost by attainder for high treason. Neither the issue of the body of the person attainted, nor, on their failure, the descendants of the person first called to the dignity, will be admitted to it without a removal of the attainer. But where the attainted person is tenant in tail-male, with a remainder in tail-male to another, the dignity becomes vested in the remainder man on failure of the issue of the person attainted. A peerage, whether by patent or writ, is forfeited by attainder for high treason; attainder for felony forfeits a peerage by writ, not one by patent. An attainted peerage cannot be restored by the crown, only by an act of parliament.

The House of Commons, besides its general power to introduce legislative measures, has the sole right to originate bills levying taxes, or affecting the public income and expenditure, and to examine into the validity of elections to its own body. The question whether it has any control over the rights of electors was the subject of a memorable contest between the Lords and Commons in 1704, in the cases of Ashby and White, and of the 'Aylesbury men' (*Hatsell's Precedents*, vol. iii.), a contest ended by the queen proroguing parliament. When inquiring into the conflicting claims of candidates for seats in parliament, the Commons have an undoubted power to determine whether electors have the right to vote. The House of Commons has the right to expel or commit to prison its own members, and to commit other persons who offend by breach of its privileges, contempt of its authority, disobedience of its orders, or invasion of its rights; but this power is limited to the duration of the session. Expulsion does not, however, create any disability to serve again in parliament. The House of Commons has also the power of impeaching offenders, who, however, are tried at the bar of the House of Lords.

The number of members of the House of Commons has varied greatly at different times. In the reign of Edward I., it seems to have been 275; in that of Edward III., 250; and of Henry VI., 300. In the reign of Henry VIII., 27 members were added for Wales, and 4 for the county and city of Chester; 4 were added for the county and city of Durham in the reign of Charles II. Between the reign of Henry VIII. and that of Charles II., 180 new members were added by the granting of royal charters to boroughs which had not previously returned representatives. Forty-five members were assigned as her proportion to Scotland at the Union, and 100 to Ireland, making the whole number of members of the House of Commons of the United Kingdom 658. The Reform Acts of 1832, 2 Will. IV. c. 45 for England, 2 and 3 Will. IV. c. 65 (amended by 4 and 5 Will. IV. c. 88, and 5 and 6 Will. IV. c. 78) for Scotland, and 2 and 3 Will. IV. c. 88 for Ireland, while leaving unaltered the whole number of members of the House of Commons, made great changes in the distribution of their seats. Fifty-six boroughs in England and Wales were entirely disfranchised; 30 which had previously returned two members were restricted to one; while 42 new boroughs were created, of which 22 were each to return two members, and 20 a single member. Several small boroughs in Wales were united to elect one member. Four members were assigned to the city of London, 2 to each of the universities of Oxford and Cambridge, and one to 133 cities and boroughs. The number of members for Scotland was increased from 45 to 53, 30 being county and 23 borough members, some of the latter representing several combined boroughs. The number of members for Ireland was increased from 100 to 105, 64 representing counties, 34 cities and boroughs, and 2 the University of Dublin.

Further extensive changes in the distribution of seats were made by the recent Reform Acts of 1867 and 1868, 30 and 31 Vict. c. 103 for England, and 31 and 32 Vict. c. 48 for Scotland. The English act deprived of its second member each borough of less than 10,000 inhabitants, and altogether disfranchised seven boroughs, giving 45 seats for re-distribution, of which 25 were given to the larger counties, 11 to new boroughs, 8 to boroughs already represented, and 1 to the University of London. The Scotch act united the counties of Selkirk and Peebles into one constituency; gave a member to the universities of Edinburgh and St. Andrews, and another to the universities of Glasgow and Aberdeen, a second member to each of the counties of Lanark, Ayr, and Aberdeen, and to the town of Dundee, and a third member to Glasgow; and constituted Hawick, Galashiels, and Selkirk into a new district of boroughs; the seven new seats required being provided for by a further disfranchisement of small English boroughs. The Irish Reform Act made no change in this. The number of 658 seats was thus left unaltered; but the disfranchisement of 9 English boroughs (7 in 1832) and 2 Irish ones, has reduced the number actually filled. The 652 seats occupied after the election of 1880 were thus distributed:

Counties.	Boroughs.	Universities.	Total.
England and Wales..	187	295	5
Scotland.....	32	26	2
Ireland.....	64	39	2
	283	360	9
			652

In English counties, prior to the act of 1832, the electoral qualification was founded on the holding of freehold property of the yearly value of 40s.: by that act every person who at the date was seized for his own life and that of another, or for any lives whatever, of a 40s. freehold, or who might be seized subsequently to the act if in occupation, or who might come into such freehold estate by marriage, marriage-settlement, devise, or promotion to any benefice or office, could still vote as a freeholder; but a person not included in these classes, acquiring a freehold subsequently to the act, had only the franchise when it was of the clear

yearly value of £10, which value was reduced to £5 by the act of 1867. Copyholders holding an estate of £10 a year, leaseholders of that value whose leases were originally granted for 60 years, leaseholders of £50 with 20 years' leases, and tenants at will occupying lands or tenements paying a rent of £50, had the franchise under the act of 1832; and the act of 1867 reduced the franchise of copyholders and leaseholders from £10 to £5, and the occupation franchise from £50 to £12. In boroughs, the old qualifications varied according to local usage, and some of the ancient rights, as that of freemen, were retained in 1832, when the franchise was bestowed on all occupiers of houses of £10 yearly value. The act of 1867 extended the borough franchise to all occupiers of dwelling-houses who have resided for 12 months on the 31st of July in any year, and have been rated to the poor-rates as ordinary occupiers, and have, on or before the 20th July, paid such rates up to the preceding 5th January, and to lodgers who have occupied for the same period lodgings of the annual value, unfurnished, of £12. In Scotland, the old county qualification consisted in being infeft in lands or superiorities holding directly of the crown of 40s. old extent (see VALUATION), or £400 Scots valued rent; and the Scotch act of 1832 reserved the rights of persons then on the roll of freeholders, or entitled to be put on it, and extended the franchise to all owners of property of the clear yearly value of £10, and to certain classes of leaseholders.

By the act of 1868, the county franchise was further extended to proprietors of lands of £5 yearly value, and occupiers of the rateable value of £14. The Scottish burghal franchise had, prior to 1832, been vested in the town-councils: the act of 1832 substituted a £10 household franchise, and that of 1868 gave the franchise to all occupiers paying rates, and to lodgers in rooms worth £10 unfurnished.

By the Irish Reform Act of 1832, various classes of freeholders were invested with the county franchise, to whom were added, by 13 and 14 Vict. c. 69, occupiers of land rated for the poor-rate at a net annual value of £12, and persons entitled to estates in fee, or in tail, or for life, at the rated value of £5. The Irish borough qualification was nearly the same as the English, but the above-mentioned statute of Victoria added to the constituency the occupiers of land and premises rated at £8. The act of 1868 made no change in the county qualification, but gave the borough franchise to occupiers of houses rated at £4, and of lodgings of the annual value of £10 unfurnished. Certain disqualifications exist from exercising the franchise on the grounds of infamy, alienage, conviction of felony, and the holding of government offices. Peers cannot vote. In the universities of Cambridge and Oxford, the constituency consists of the doctors and masters of arts; in Dublin, of the fellows, scholars, and graduates of Trinity College. In London University, the graduates form the constituency; in the Scotch universities, the chancellor, the members of the university court, the professors, and the members of general council. Under the acts of 1867 and 1868, in London, where four members are returned, each elector has only three votes; and in Glasgow, which returns three members, each elector has but two votes.

The Reform Acts of 1832 introduced a system of registration of voters for the three divisions of the United Kingdom. In England, lists of voters are prepared by the overseers of each parish, and on certain days courts are held by barristers appointed by the chief-justice and the senior judge of each summer circuit to revise these lists, when claims may be made for persons omitted, and objections offered to names standing on the list. If an objection be sustained, the name is struck off the list, there being an appeal from the decision of the revising barrister to the Court of Common Pleas. In Scotland, a register of persons entitled to vote is made up annually in counties and boroughs in terms of the Registration of Voters (Scotland) Act, 24 and 25 Vict. c. 23, which register is printed, and may be had for a small price. Voters are thus put on the roll without trouble to themselves, and, in point of fact, without their consent. Enrolment, however, may be challenged, in which case objections are heard and determined by the sheriffs, subject (under the act of 1863) to appeal to a tribunal composed of three judges of the Court of Session. The registration system of Ireland introduced by the Reform Act resembles that of England; and by 16 and 17 Vict. c. 58, provision is made for the annual revision of the list of voters for the city of Dublin.

A property qualification of £600 a year in candidates for counties, and £300 in candidates for boroughs, which had previously existed in England and Ireland, was left untouched in 1831, but has been abolished by 21 and 22 Vict. c. 26. Scotch peers, though not representative peers, are disqualified from sitting in the House of Commons. Irish peers may represent any constituency in Great Britain, but not in Ireland. A disqualification is also attached to judges (except the Master of the Rolls), clergymen of the Established Church of any of the three kingdoms, Roman Catholic priests, revenue officers, persons convicted of treason and felony, and aliens even when naturalized, unless the right have

been conceded in express terms. Sheriffs cannot sit for their own counties, and government contractors are disqualified, a disqualification which does not extend to contractors for government loans. A member becoming bankrupt is incapacitated from sitting or voting.

When a new parliament has to be assembled, the Lord Chancellor, by order of the sovereign, directs the Clerk of the Crown to prepare and issue, under the Great Seal, writs to the sheriffs of counties, both for the counties and the boroughs. A sheriff, on receiving the writ for a county, appoints a day for the election, and by the practice prior to the Ballot Act, 1872 (35 and 36 Vict. c. 33), on the day fixed, he proclaimed the writ. If no more candidates were then proposed than were to be elected, he declared them duly elected; if there was opposition, a show of hands was asked, and the sheriff declared who had the majority. If a poll was demanded by the opposite party, the election was adjourned. The electors of each district voted at their several polling-places, and at the termination of the poll, the return was transmitted to the sheriff, who proclaimed the successful candidate. In borough elections in England and Ireland, the sheriff, on receiving the writ, issued his precept to the returning officer of the municipality, who superintended the election; in Scotland, the sheriff himself superintended the borough as well as the county elections. The names of the persons elected, both in counties and boroughs, were returned by the sheriff to the Clerk of the Crown. The candidates are now nominated by a writing signed by two electors, as proposer and seconder, and eight others as consenting, and delivered to the returning officer; if on expiry of an hour from the time fixed, there are more candidates than vacancies, the election is adjourned, and a poll taken. The vote is given by Ballot (q. v.), and the result announced by the returning officer, and returned to the Clerk of the Crown in Chancery. Vacancies occurring after a general election are supplied by new writs issued by authority of the House. When it is determined that a writ should be amended, the Clerk of the Crown is ordered to attend the House, and amend it accordingly.

A member of the House of Commons cannot, in theory, resign his seat; but on the acceptance of any office of profit under the crown, his election is, by an act of Queen Anne, declared void, and a new writ issues, he being, however, eligible for re-election. By the Reform Act of 1867, members who already hold certain offices do not vacate their seats on the acceptance of certain other offices enumerated, the list seemingly comprehending all offices usually held by members. The resignation of office is held not to be complete until the appointment of a successor; and on the resumption of office, the seat is held not to have been vacated. A first commission in the army or navy vacates a seat; subsequent commissions do not do so. A member wishing to resign usually applies for the stewardship of the Chiltern Hundreds (q. v.).

Privilege.—Both Houses of Parliament possess extensive privileges for the maintenance of their authority and the protection of individual members. Some of these privileges have well-defined limits; others are so vague in their extent as occasionally to lead to conflicts between parliament and the courts of law. The privilege of speech is claimed of the sovereign by the Speaker of the House of Commons at the opening of every new parliament. At the same time, any member using offensive expressions may be called to the bar to receive a reprimand from the Speaker; or, if the offence be grave, may be committed for contempt, in which case he is sent either to the Tower or to Newgate. Persons not members of the House may also be committed for breach of privilege, and no one committed for contempt can be admitted to bail, nor can the cause of commitment be inquired into by the courts of law.

The publication of the debates of either House has repeatedly been declared a breach of privilege; but for a long time back this privilege has been practically waived, except where the reports are false and perverted. Publication of the evidence before a select committee previously to its being reported is punished as a breach of privilege. Libellous reflections on the character and proceedings of parliament, or of members of the House, come under the same category, as also does assailing or threatening a member. Wilful disobedience to the orders of the House is punishable as a breach of privilege; but if orders be given beyond the jurisdiction of the House, their enforcement may be questioned in a court of law. The offer of a bribe to, or its acceptance by a member is a breach of privilege; so also is any interference with the officers of the House in the execution of their duty, or tampering with witnesses who are to be examined before the House, or a committee of the House. Members of both Houses are free from arrest or imprisonment in civil matters, a privilege which is permanent in the case of peers, extending also to peeresses, whether by creation or marriage (though the latter lose it by subsequently marrying a commoner), and to peers and peeresses of Scotland and Ireland, whether representative or not. It continues in the case of members of the House of Commons

during the sitting of parliament, for 40 days after each prorogation, for 40 days prior to the day to which parliament is prorogued, and for a reasonable time after a dissolution. Witnesses summoned to attend before parliament or parliamentary committees, and other persons in attendance on the business of parliament, are also protected from arrest. Protection is not claimable from arrest for any indictable offence. Counsel are protected for any statements that they may make professionally.

Meeting of a New Parliament.—On the day appointed for the meeting of a new parliament, the members of the two Houses assemble in their respective chambers. In the Lords, the Lord Chancellor acquaints the House that 'her Majesty, not thinking it fit to be personally present here this day, had been pleased to cause a commission to be issued under the Great Seal, in order to the opening and holding of the parliament.' The Lords Commissioners, being in their robes, and seated between the throne and woolsack, then command the Gentleman Usher of the Black Rod to let the Commons know that the 'Lords Commissioners desire their immediate attendance in this House to hear the Commission read.' Meantime, in the Lower House, the Clerk of the Crown in Chancery has delivered to the Clerk of the House a list of the members returned to serve; and on receiving the message from Black Rod, the Commons go up to the House of Lords. The commission having been read in presence of the members of both Houses, the Lord Chancellor opens the parliament by stating 'that her Majesty will, as soon as the members of both Houses shall be sworn, declare the causes of her calling this parliament; and it being necessary that a Speaker of the House of Commons should first be chosen, that you, gentlemen of the House of Commons, repair to the place where you are to sit, and there proceed to the appointment of some proper person as your Speaker, and that you present such person whom you shall so choose here to-morrow at o'clock, for her Majesty's royal approbation.' The Commons immediately withdraw, and, returning to their own House, proceed to elect a Speaker.

Till a Speaker be elected, the clerk acts as Speaker, standing and pointing to members as they rise to speak, and then sitting down. If only one candidate be proposed for the office, the motion, after being seconded, is supported by an influential member, generally the leader of the House of Commons; and the member proposed, having expressed his sense of the honor meant to be conferred on him, is called by the House to the chair, to which he is led by his proposer and seconder. If another member be proposed and seconded, a debate ensues; and at its close, the clerk puts the question, that the member first proposed 'do take the chair of the House as Speaker.' If the House divide, he directs one party to go into the right lobby, and the other into the left, and appoints two tellers for each. If the majority be in favor of the member first proposed, he is led to the chair; if not, a similar question being put regarding the other member, and answered in the affirmative, he is conducted to the chair. The Speaker-elect expresses his thanks for the honor conferred on him, and takes his seat; on which, the mace is laid on the table, where it is always placed during the sitting of the House with the Speaker in the chair. He is then congratulated by some leading member, and the House adjourns. The next day, the Speaker-elect, on the arrival of Black Rod, proceeds with the Commons to the House of Lords, where his election is approved by the Lord Chancellor. He then lays claim, on behalf of the Commons, to their ancient rights and privileges, which being confirmed, he retires with the Commons from the bar. Nearly the same forms are observed on the election of a new Speaker, when a vacancy occurs by death or resignation in the course of the session.

The members of both Houses then take the oath prescribed by law. See OATH; ABJURATION. In the Upper House, the Lord Chancellor first takes the oath singly at the table. The Clerk of the Crown delivers a certificate of the return of the Scottish representative peers, and Garter King-at-arms the roll of the lords temporal, after which the lords present take and subscribe the oath. Peers who have been newly created by letters-patent present their patents to the Lord Chancellor, are introduced in their robes between two other peers of their own dignity, preceded by Black Rod and Garter, and conducted to their places. The same ceremony is observed in the case of peers who have received a writ of summons—a formality necessary when a member of the Lower House succeeds to a peerage; otherwise his seat does not become vacant. A bishop is introduced by two other bishops, without the formalities observed with temporal lords. Peers by descent have a right to take their seats without introduction; peers by special limitation in remainder have to be introduced. In the Commons, the speaker first subscribes the oath, standing on the upper step of the chair, and is followed by the other members. Members on taking the oath are introduced by the Clerk of the House to the Speaker. Members returned on new writs in the course of the session, after taking the oath, are introduced between two members. They must bring a certificate

of their return from the Clerk of the Crown. On the demise of the crown, the oaths must be taken anew in both Houses.

When the greater part of the members of both Houses have been sworn, the causes of calling the parliament are declared by the sovereign either in person or by commission. In the former case, the Queen proceeds in state to the House of Lords, and commands Black Rod to let the Commons know 'that it is her Majesty's pleasure that they attend her immediately in this House.' Black Rod proceeds to the House of Commons, and formally commands their attendance, on which the Speaker and the Commons go up to the bar of the House of Lords, and the queen reads her speech, which is delivered to her by the Lord Chancellor kneeling on one knee. Of late years the practice has been revived of the Lord Chancellor reading the royal speech in the Queen's presence. When parliament is opened by commission, the sovereign not being personally present, the Lord Chancellor reads the royal speech to both Houses. Immediately after the royal speech is read, the House is adjourned during pleasure; but both Houses are resumed in the afternoon, for the purpose of voting an address in answer to the speech from the throne. In each House it is common to begin business by reading some bill *pro forma*, in order to assert the right of deliberating without reference to the immediate cause of summons. The royal speech is then read, and an address moved in answer to it. Two members in each House are chosen by the ministry to move and second the address. The preparation of the address is referred to a select committee; it is twice read, may be amended, and when finally agreed on, it is ordered to be presented to her Majesty.

Adjournment, Prorogation, and Dissolution.—Adjournment of parliament is but the continuance of the session from one day to another. Either House may adjourn separately on its own authority, with this restriction, introduced by Act 39 and 40 Geo. III. c. 14, that the sovereign, with advice of the privy council, may issue a proclamation appointing parliament to meet within not less than 14 days, notwithstanding an adjournment beyond that period. On reassembling, the House can again take up business which was left unfinished. A prorogation differs from an adjournment in this respect, that it not merely suspends all business, but quashes all proceedings pending at the time, except impeachments by the Commons, and appeals and writs of error in the Lords. William III. prorogued parliament from 21st October to 23d October 1689, in order to renew the Bill of Rights, regarding which a difference had arisen between the two Houses that was fatal to its progress. It being a rule that a bill of the same substance cannot be introduced twice in the same session, a prorogation has sometimes been resorted to, to enable a second bill to be brought in. Parliament can only be prorogued by the sovereign; and this may be done by having her command signified in her presence by the Lord Chancellor to both Houses, by writ under the Great Seal, by commission or by proclamation. Till recently, a proclamation for the prorogation of parliament from the day to which it stood summoned or prorogued to another day, was followed by a writ or commission; but by 80 and 81 Vict. the royal proclamation alone prorogues parliament, except at the close of a session.

Parliament comes to an end by dissolution. This dissolution may be by the will of the sovereign expressed in person or by her representatives. Having been first prorogued, it is dissolved by a royal proclamation, and by the same instrument it is declared that the chancellor of Great Britain and chancellor of Ireland have been respectively ordered to issue out writs for calling a new parliament. By 6 Anne c. 37, a parliament was determined six months after the demise of the crown; but by the Reform Act of 1867, the parliament in being at any future demise of the crown shall not be determined by such demise, but shall continue as long as it would otherwise have continued unless dissolved by the crown. Were the power of dissolving the parliament not vested in the executive, there would be a danger of its becoming permanent, and encroaching on the royal authority, so as to destroy the balance of the constitution. An example of this danger is shown in the Long Parliament, to which Charles I. conceded that it should not be dissolved till such time as it dissolved itself. If the Houses of Parliament encroach on the executive, or act factiously or injudiciously, the crown may, by a dissolution, bring their proceedings to an end, and appeal to the people by sending the members of the House of Commons to give an account of their conduct to their constituents.

There was originally no limit to the duration of a parliament except the will of the sovereign. By 6 Will. and Mary, c. 2, the continuance of a parliament was limited to three years, a term afterwards extended by 1 Geo. I. c. 38, to seven years. The same act of William and Mary enacts that parliament shall assemble once in three years at the least; but the practice of granting the Mutiny Act and the Budget for a year only, makes it necessary that it should assemble annually.

Conduct of Business.—Each House is presided over by its Speaker. The Speaker of the House of Commons does not take

part in a debate, offer his opinion, or vote on ordinary occasions; but, in case of equality, he has a casting vote: his duty is to decide all questions which relate to order, putting the matter at issue in a substantive form for the decision of the House, if his own decision is not assented to. He explains any doubts that may arise on bills. He determines the precedence of members rising to address the House. He examines witnesses at the bar. At the close of the session, he addresses the sovereign on presenting the money-bills passed during the session for the royal assent. He nominates the tellers on a division, and makes known the votes to the House. He may commit members to custody during the pleasure of the House, a confinement which terminates with the close of the session. When a vacancy occurs by death, he signs the warrant to the Clerk of the Crown to make out the writ for the election of a new member. He audits the accounts of the receiver of fees, and directs the printing of the votes and proceedings of the House. The Lord Chancellor, or Lord Keeper of the Great Seal, is the Speaker of the House of Lords; in his absence, the Chairman of the Committee of Ways and Means takes the chair. The Speaker is not, as in the Lower House, charged with the maintenance of order, or the decision who is to be heard, which rest with the House itself. The Chairman of the Committee of Ways and Means of the House of Commons as Deputy-speaker, performs the Speaker's duties in his absence. The chief officers of the House of Lords are the Clerk of the Parliaments, who takes minutes of the proceedings of the House; the Gentleman Usher of the Black Rod, who, with his deputy, the Yeoman Usher, is sent to desire the attendance of the Commons, executes orders for committal, and assists in various ceremonies; the Clerk-assistant; and the Sergeant-at-arms, who attends the Lord Chancellor with the mace, and executes the orders of the House for the attachment of delinquents. The chief officers of the Commons are the Clerk of the House, the Sergeant-at-arms, the Clerk-assistant, and Second Clerk-assistant.

Each House has its *Standing Orders*, or regulations, adopted at different periods, relating partly to internal order, partly to certain preliminaries required in the introduction of bills and promulgation of statutes. A standing order endures till repealed (or 'vacated,' as it is called in the Upper House); but each House is also in the practice of agreeing to certain orders or *resolutions* of uncertain duration declaratory of its practice, which are considered less formally binding than standing orders.

The House of Lords usually meets at 5 P.M.; the Commons at a quarter before 4, except on Wednesdays and other days specially appointed for morning sittings. In the Lords, the Chancellor, as Speaker, sits on the woolsack. A standing order, which is never enforced, requires the Lords to take place according to precedence. Practically, the bishops sit together on the right hand of the throne; the members of the administration on the front bench on the right hand of the woolsack adjoining the bishops, and the peers who usually vote with them occupy the other benches on that side. The peers in opposition are ranged on the opposite side, and those considered politically neutral occupy the cross benches between the table and the bar. In the House of Commons, the front bench on the right hand of the chair is reserved for the ministry, and called the Treasury Bench, the front bench on the opposite side being occupied by the leaders of the opposition. By ancient custom and orders of both Houses, rarely enforced, strangers are excluded while the Houses are sitting.

Prayers are read before business is begun—in the House of Lords by a bishop; in the House of Commons by the chaplain. Every member is bound to attend the House—in the Lower House, personally; in the Upper personally, or by proxy; but in ordinary circumstances, this obligation is not enforced. The House of Lords may proceed to business when three peers are present; in the Commons, forty members are required to constitute a House for the despatch of business. The Speaker counts the House at four; and if that number be not then present, or if it be noticed, or appear on a division, that fewer than forty members are present, the House is adjourned. A call of the House is an expedient to secure attendance on important occasions; when it is made, members absent without leave may be ordered to be taken into custody. When matters of great interest are to be debated in the Upper House, the Lords are 'summoned.'

To make a motion, or, more properly, to *move the House*, is to propose a question, and notices of motion should be given on a previous day. The Commons are in the practice of setting apart Mondays, Wednesdays, Thursdays, and Fridays for considering *orders of the day*, or matters which the House had already agreed to consider on a particular day, and to reserve Tuesdays for motions. Government orders take precedence of others on all order days except Wednesdays, which are generally reserved for the orders of independent members. Notices of motion may be given not more than four motion days before their discussion; that is, ordinarily, not more than a month in advance.

Questions of privilege may be considered without previous

notices, and take precedence both of other motions and orders of the day. A motion may be accompanied by a speech, and must in the Lower House be seconded, otherwise there is no question before the House. In purely formal motions this rule is not observed, and an order of the day may be moved without a seconder. A seconder is not required in the House of Lords. A motion in the Commons must be reduced to writing by the mover, and delivered to the Speaker, who, when it has been seconded, puts it to the House; it cannot then be withdrawn without leave of the House. In the Lords, when a motion has been made, a question is proposed 'that the motion be agreed to.' When an amendment is proposed to a question, the original motion cannot be withdrawn till the amendment has been either withdrawn or negatived. An amendment is properly such an alteration on a motion by striking out or adding words, or both, as may enable members to vote for it who would not have done so otherwise.

A question may be evaded, superseded, or got rid of, in four ways: 1. By adjournment. Any member in possession of the House may move 'that the House do now adjourn.' The House may also be adjourned, even while a member is speaking, on its being noticed that there are fewer than forty members present. The motion, 'that the debate be now adjourned,' does not supersede the question, but merely defers the decision of the House. 2. By a motion, that the orders of the day be now read, which may be put and carried on days on which notices of motion have precedence. 3. By what is called *moving the previous question*. The act of the Speaker in putting the question is intercepted by a motion, 'that the question be now put.' The mover and seconder of this motion vote against it; and if it be resolved in the negative, the Speaker is prevented from putting the main question, which, however, may be brought forward on another day. 4. By an amendment substituting words of an entirely different import for those of the motion, so that the sense of the House is taken on a totally different question.

When the question is put by the Speaker in the Lords, the respective parties exclaim 'content' or 'non-content'; in the Commons, the expression used is 'aye' or 'no.' The Speaker signifies his opinion which party have the majority, and if the House acquiesce, the question is said to be resolved in the affirmative or negative; when his decision is disputed, the numbers must be counted by a division. Both Houses now divide by the content or ayes going into the right lobby, and the non-contents or noes into the left, each being counted by tellers appointed by the Speaker. In the House of Commons, two clerks with printed lists of the members put a mark to the name of each as he re-enters the House, so as to secure accuracy in the division-lists. The Speaker of the Commons, who does not otherwise vote or take part in a debate, has a casting-vote in case of equality. In the House of Lords, the Speaker is, on the other hand, not disqualified from taking part in a debate; he votes on divisions, but has no casting vote; and on an equality, the non-contents prevail. The system of pairing commonly practised, though never directly recognized by the House, enables members on opposite sides to absent themselves for a time agreed on, each neutralizing the votes of the other. A member of the Upper House may, with leave of the House, by a protest enter his dissent from a vote of the House, and its grounds. Every protest is entered on the Journals of the House, together with the names of all the lords who concur in it.

No question or bill is allowed to be offered in either House substantially the same with one on which the judgment of that House has already been expressed in the current session. A resolution of the House, however, may be rescinded, and an order discharged; and by 13 and 14 Vict. c. 21, it is provided that every act may be altered, amended, or repealed in the same session of parliament.

In debate, a member of the Commons addresses the Speaker; a member of the Upper House the lords generally, in both cases standing and uncovered. No member may speak except when there is a question before the House, or with the view to propose a motion or amendment, the only admitted exceptions being in putting questions to ministers of the crown, or to members concerned in some business which is before the House, and in explaining personal matters. A member is not allowed to speak twice to the same question except in explanation, and the proposer, in some cases, in reply—a restriction which does not apply in committee. By the rules adopted by both Houses for preserving order in debate, no allusion is allowed two debates of the same session on a question not under discussion, or to debates in the other House of Parliament. All reflections on any determination of the House are prohibited, except when made with a view of moving that the determination be rescinded; so is the mention by a member of her Majesty's name either irreverently, or to influence the debate. No member is allowed to refer to another by name, or otherwise than by the rank or office which he enjoys, or place which he represents. The speaker *naming* a member to the House, is an old established form of censure.

To escape obstruction, the House of Commons adopted, in 1682, new procedure rules, securing the right of deciding when a debate should be closed and the vote taken. For these rules see end of article.

Messages.—It is often found necessary for the Houses to communicate with each other. Messages from the Lords were formerly sent by Masters in Chancery or judges, while the Commons sent a deputation of their own members. According to an arrangement adopted in 1855, one of the clerks of either House may be the bearer of a message.

Committees.—Parliamentary committees are either 'of the whole House,' or 'select.' (For the new *Grand Committees*, see end of article.) A committee of the whole House is the House itself, with a chairman instead of the Speaker presiding. The chair is taken in the Lords by the chairman of committees appointed at the beginning of each session, in the Commons by the chairman of the Committee of Ways and Means. Matters relating to religion, trade, the imposition of taxes, or the granting of public money, are generally considered in committee before legislation, as also are the provisions of any public bill. Proceedings are conducted nearly as when the House is sitting, the Lords being addressed in the Upper House, and in the Lower the chairman, who has the same powers to maintain order as the Speaker, and a casting vote in case of equality. In committees of the Commons, as in the House itself, a quorum of forty members is required; but if that number are not present, the Speaker must resume the chair to adjourn the House. A motion in committee need not be seconded, and there is a more unlimited power of debate than in the House, members being at liberty to speak any number of times on the same question. A motion for 'the previous question' is not allowed. When the business of the committee is not concluded on the day of sitting, the House is resumed, and the chairman moves 'that the House be again put into committee on a future day,' in the Lords, and in the Commons reports progress, and asks leave to sit again.

Select committees are composed of a limited number of members appointed to inquire into any matter, and report. In the Commons, it is usual to give select committees power to send for persons, papers, and records; in the Lords, they may, without any special authority, summon witnesses. In neither House can a committee enforce the attendance of a witness; this must be done, when necessary, by the House itself. The Commons have certain standing orders for insuring the efficiency of committees, and impartiality in their appointment. No committee is to consist of more than fifteen. Members moving for a committee must ascertain whether the members whom they propose to name will attend. Lists of the members serving on each committee are to be affixed in the committee clerk's office and the lobby. To every question asked of a witness, the name of the member who asks it is to be prefixed in the minutes of evidence laid before the House; and the names of the members present at each sitting, and, in the event of a division, the question proposed, the name of the proposer, and the votes of each member, are to be entered on the minutes, and reported to the House. In the Lords there are no special rules regarding the appointment and constitution of committees; but resolutions containing arrangements similar to those of the Commons regarding questions to witnesses, minutes of proceedings, and divisions, have been adopted since 1852. Select committees have the power of adjournment from time to time, and sometimes from place to place. By an anomaly not easily explained, the Commons have always been considered not to have the power of administering oaths; a power of examining on oath has, however, by statute been granted to election committees, and committees on private bills. In the House of Lords, witnesses had formerly to attend at the bar of the House to be sworn; but the oath may now be administered by any committee of the House. Except where leave of absence has been obtained, no member, unless above the age of sixty, can excuse himself from serving on committees, or for not attending when his attendance has been made compulsory by order of the House. In committees on private bills in the Commons, the chairman has a deliberative as well as a casting vote. Since 1864, joint committees of both Houses, composed of an equal number of members of each, have occasionally been appointed.

Bills.—The principal business which occupies both Houses is the passing of bills. In early times, laws were enacted in the form of petitions from the Commons, which were entered on the Rolls of Parliament, with the king's answers subjoined; and at the close of the session, those imperfect records were drawn up in the form of a statute, which was entered on the Statute Rolls. It was found that, on undergoing this process, the acts passed by the parliament were often both added to and mutilated, and much of the legislative power practically came into the hands of the judges. Bills in the form of complete statutes were first introduced in the reign of Henry VI. Bills are either public or private; the former affect the general interests of the community, the latter relate to local matters. Public bills are intro-

duced directly by members; private bills by petitions from the parties interested, presented by members. Bills may originate in either House; but the exclusive right of the Commons to deal with all legislation regarding taxes or supplies, makes it necessary and expedient that by far the greater part of both public and private bills, except such as are of a purely personal nature, should originate in the Lower House. Bills regarding restitution of honors originate in the House of Lords. One description of act alone originates with the crown—an act of grace or pardon. It is read only once in each House, and cannot be amended, but must be accepted in the form in which it is received from the crown, or rejected.

Public Bills.—In the House of Lords, any member may present a bill. In the Commons, any member may move for leave to bring in a bill, except it be for imposing a tax, when an order of the House is required. When the motion is seconded, and leave given, the mover and seconder are ordered to prepare and bring in the bill. Such bills, however, as relate to religion, trade, grants of public money, or taxation, are required to be introduced by the House itself, on the report of a committee of the whole House. A bill is drawn out on paper, with blanks or italics where any part is doubtful, or where sums have to be inserted. It is read a first time, and a day fixed for a second reading, allowing a sufficient interval to let it be printed and circulated. When ready, which is often as soon as the motion for leave to bring it in has been agreed to, it is presented at the bar by one of the members who were ordered to prepare and bring it in, and afterwards, on an intimation from the Speaker, brought up to the table. The question is put, 'That the bill be now read a first time,' which is rarely objected to; and in the Commons can only be opposed by a division. The short title of the bill, as entered in the orders of the day and endorsed on the bill, is then read aloud, which is accounted sufficient compliance with the order of the House. A day is then appointed for considering the question, 'that the bill be read a second time,' allowing a sufficient interval to let it be printed and circulated. At the second reading, the member in charge of the bill moves 'that the bill be now read a second time.' This is the usual time for opposing a bill whose general principle is disapproved. This is done by an amendment to the question, by leaving out the word 'now,' and adding 'this day three months,' 'this day six months,' or some other time beyond the probable duration of the session.

Counsel are sometimes allowed to plead at the second reading or other stages. If the bill be approved on the second reading, it is committed, either to a select committee, or to a committee of the whole House, to consider its provisions in detail. When the proceedings in committee are terminated, the bill is reported to the House with amendments, which may be agreed to, amended, or disagreed to. It is then ordered to be read a third time, when the entire measure is reviewed. No amendments, except what are verbal, can then be made, and the question is put to the House, 'That this bill do now pass.' The title of the bill is last settled. The bill, when passed by the Commons, is sent to the Lords, where it goes through the same forms: if rejected, no further notice is taken of it; if passed, a message is sent to the Commons that the bill is agreed to. If amendments have been made, they are sent down along with the bill to be discussed by the Commons; and if they are not agreed to, a conference is demanded by the Commons, to offer reasons for disagreeing to the amendments. A conference is a mode of communicating on important matters between the Houses, in which each House is brought into direct contact with the other by a deputation of its own members—the time and place of meeting being always fixed by the Lords. A conference is conducted, for both Houses, by managers, who, on the part of the House desiring the conference (in the case supposed the Commons), consist of the members who have drawn up the reasons, with others sometimes added. If the Lords be not satisfied with the reasons offered, a second conference is desired, after which what is called a 'free conference' may be demanded, in which the managers have more discretion vested in them to advance what arguments they please.

No free conference has been held since 1740. By resolutions of both Houses, agreed to in 1851, reasons for disagreement from amendments may be communicated by messages without a conference, unless the other House should desire a conference; and since that time, there has been but one instance of a conference where a message would have been available. If the Commons eventually agree to the amendments, the bill is sent back to the Lords; if not, it is dropped. The same forms are gone through when a bill originates in the House of Lords. The official record of the assent of one House to the bills passed, or amendments made by the other, is an endorsement on the bill in Norman French. Thus, when a bill is passed by the Commons, the Clerk of the House writes on the top of it, 'Soit baillé aux seigneurs.' When the Lords make amendment to a bill, it is returned with the endorsement, 'A ceste bille avesque des amendments les seigneurs sont assentus.' When it is sent back with these amendments

agreed to, the Clerk of the House of Commons writes, 'Aces amendments les Communes sont assentus.' When both Houses have agreed to a bill, it is deposited in the House of Lords, to await the royal assent, unless it be a money-bill, which is sent back to the Commons.

Private Bills.—In private bills, the functions of parliament partake of the judicial as well as the legislative character, and the difficulties in reconciling the interests of the public and of individuals, often give rise to inquiries too extensive for the House to undertake, which therefore delegates them to committees. The standing orders require certain notices to be given to parties interested by personal service, and to the public by advertisement. The practice in both Houses now is for all petitions for private bills to be referred to four 'examiners,' two from the Lords and two from the Commons, whose duty it is to examine whether certain notices and other forms required by the standing orders of the House have been complied with. If the report be favorable, leave is given to bring in the bill; if unfavorable, it is referred to a committee, called the Committee on Standing Orders, who report on the propriety of relaxing the standing orders in this individual case—should they report unfavorably, it is still in the power of the House to relax the standing orders, though this is rarely done. Three days must elapse between the first and second reading.

At the second reading, the principle is considered, as in the case of public bills; and if the bill be carried, it is referred, if not a railway, canal, or divorce bill, to the 'Committee of Selection,' consisting of the chairman of the Standing Orders Committee, and five other members nominated at the beginning of the session, whose functions are to classify the bills, to nominate the Committees on them, and to arrange their time of sitting. A railway or canal bill is referred to the 'General Committee of Railway and Canal Bills.' This committee forms bills of this class into groups, and appoints the chairman of the committee which is to sit on each bill from its own body, the remaining members, four in number, being chosen from the Committee of Selection. Before the sitting of the committee, every private bill, whether opposed or unopposed, must be examined by the chairman of the Committee of Ways and Means and his council. It is also laid before the chairman of the Lords' Committee and his council, and effect is given to their observations, a proceeding which greatly facilitates the after progress of the bill in the House of Lords. The Board of Trade, the Secretary of State for the Home Department, the Lords Commissioners of the Admiralty, and the Commissioners of Woods and Forests, also exercise a supervision over private bills of various kinds, by which the respective rights of their departments may be supposed to be encroached on. In the House of Lords, estate bills are referred to the judges. Every bill, at the first reading, is referred to the Examiners, before whom compliance with such standing orders as have not been previously inquired into must be proved. The Standing Orders Committee of the Lords is now assimilated in functions to that of the Commons. The bill is returned to the Commons either with amendments, or with a message that it is agreed to without amendments. In case of disagreement between the Houses, the same forms are observed as in public bills.

In recent times, the necessity for obtaining private acts has been, in many cases, obviated by general laws adapted to different classes of objects, of which parties are enabled to avail themselves, instead of applying to parliament for special powers.

Royal Assent.—A bill becomes a statute or act of parliament on receiving the royal assent, which is given in the House of Lords, the Commons being also present at the bar. It is given in either of two ways: by letters-patent under the Great Seal; signed by the sovereign's own hand, and communicated to the two Houses by commissioners; or by the sovereign present in person in the House of Lords. When the royal assent is given by commission, three or more of the Lords Commissioners command Black Rod to signify to the Commons that their attendance is desired, on which the Commons, with the Speaker, immediately come to the bar. The commission is then read at length; and the titles of all the bills being read by the Clerk of the Crown, the royal assent to each is signified by the Clerk of the Parliaments in Norman-French, and so entered on the Lords' Journals. In assenting to a public bill, the words used are: 'Le roy [la reyne] le veult;' to a private bill: 'Soit fait comme il est désiré;' and to a bill of supply (which is presented by the Speaker, and receives the royal assent before all other bills): 'Le roy remercie ses bons sujets, accepte leur benevolence, et ainsi le veult.' In the case of an act of grace, which has originated with the crown, there was, till lately, no further expression of the royal assent; but the Clerk of the Parliaments, having read its title, said: 'Les prélats, seigneurs, et communes, en ce présent parlement assemblés, au nom de tous vos auctres sujets, remercient très-humblement vostre Majesté, et prient à Dieu vous donner en santé bonne vie et longue.' the royal assent, however, has been latterly given to acts of grace in the usual form. The refusal

of the royal assent is announced by the words: 'Le roy s'aviserà.' But the necessity for such refusal is generally removed by the observance of the constitutional principle, that the queen has no will but that of her ministers, who only continue in office so long as they have the confidence of parliament. The last instance in which the royal assent was refused was by Queen Anne in 1707, regarding a bill for settling the militia in Scotland.

The royal assent is seldom given in person, except at the close of a session, when the queen attends to prorogue parliament, and then signifies her assent to such bills as have been passed since the last commission was issued; but bills providing for the honor and dignity of the crown, and bills for settling the civil lists, have generally been assented to by the sovereign in person, immediately after they have passed both houses. When the royal assent is given in person, the Clerk of the Crown reads the titles of the bills; and the Clerk of the Parliaments, who has previously received her Majesty's commands in the robing room, makes an obeisance to the throne, and signifies her Majesty's assent, as already described, the queen giving a gentle inclination.

Supplies.—Prior to 1688, in addition to parliamentary taxation, imposts were sometimes levied by an exercise of the royal prerogative. Since the Revolution, no taxes have been raised otherwise than by parliamentary authority. The Commons have the exclusive right to impose taxes and vote money for the public service. The Lords cannot even make an alteration in a bill of supply, except to correct a clerical error. The Lords are not even entitled to insert in a bill any pecuniary penalties, or to alter the amount or application of any penalty imposed by the Commons; a rule whose rigid assertion has been found to be attended with so much inconvenience that there has latterly been a disposition to relax it. If a bill containing provisions which make a pecuniary charge on the public originate in the Lords, any such provisions are struck out in the bill as sent to the Commons. In the Commons, these provisions are printed in red ink, and supposed to be blank, and may be agreed to in committee. But though the Commons has the exclusive right to grant supplies, a grant requires the ultimate assent of the queen and the House of Lords.

The public revenue of the crown is derived in part from permanent charges on the consolidated fund, and in part from actual grants for specific public services, which require the yearly sanction of parliament. On the opening of parliament, the queen demands from the Commons the annual provision for the public services, and directs estimates to be laid before them. On agreeing to the address in answer to the royal speech, the Commons order the speech to be taken into consideration on another day. On the arrival of that day, a motion is made: 'That a supply be granted to her Majesty,' and the House resolves into a committee to consider that motion. On the day appointed, the committee sits and agrees that a supply be granted, which, being reported, is agreed to by the House. The House then appoints another day on which it resolves itself into a 'Committee of Supply.' The estimates for the army, navy, and ordnance departments, are first laid before the committee; then the estimates for civil services, known as the miscellaneous estimates. The first business of the Committee of Supply is to elect a chairman, who is known as the Chairman of the Committee of Ways and Means, over which he also presides. When the first report of the Committee of Supply has been received and agreed to, a day is appointed for the House to resolve itself into a 'Committee of Ways and Means.' This committee is not appointed till a sum has been voted by the House, nor is it afterwards allowed to vote in excess of the expenditure voted by the Committee of Supply. It is the function of the Committee of Supply to consider what specific grants are to be voted, and of the Committee of Ways and Means to determine how the funds shall be raised which are voted by the Committee of Supply.

Without special parliamentary authority, the consolidated fund could not be applied to meet the supplies voted for the service of the year; but to make it so available, the Committee of Ways and Means votes general grants from time to time out of the consolidated fund 'towards making good the supply granted to her Majesty;' and bills are founded on the resolutions of the committee, by which the treasury receives authority to issue the requisite amount from the consolidated fund for the service of the year. It belongs to the Committee of Ways and Means to determine what sums shall be raised by exchequer bills in anticipation of the annual revenue, to make up the supply granted to her Majesty. When the Committee of Supply has determined the number of men that shall be maintained during the year for the army and sea-service, and its resolutions have been agreed to, the *Mutiny Bill* and *Marine Mutiny Bill* are brought in, providing respectively for the discipline of the troops and marines when on shore. Apart from this annual sanction, the maintenance of a standing army in time of peace would be illegal, and the army and marines would be relieved from all martial discipline. The Committee of Ways and Means receives the annual financial statement from

the Chancellor of the Exchequer, popularly called the *Budget*. That minister gives a general view of the resources of the country, and of the financial policy of the government, and presents a probable estimate of income and expenditure for the twelve months ending on the 12th of April of the following year. He states what taxes he intends to reduce, and what new ones he means to impose, and ends by proposing resolutions for the adoption of the committee, which, when reported to the House, form the groundwork of bills for accomplishing the financial objects proposed.

The charges for collecting the revenue, have, since 1854, been brought under the supervision of the House of Commons; and estimates are voted for the revenue departments. A new tax cannot be proposed except by a minister of the crown. The resolutions of Committees of Supply and of Ways and Means are reported on a day appointed by the House, and read a first time without a question, and a second time on a question put from the chair, and are agreed to by the House, or may be disagreed to, amended, postponed, or recommitted. When the Committee of Supply is closed, the Committee of Ways and Means authorizes the application of money from the consolidated fund, the surplus of ways and means, and sums in the Exchequer, to meet the grant and services of the year, and the resolutions of the committee are carried into effect by the Consolidated Fund Bill, or as it is often called, the *Appropriation Bill*. By a standing order of April 3, 1862, a standing Committee of Public Accounts is appointed at the beginning of each session to examine into the appropriation of the sums granted by parliament to meet the public expenditure. Taxes of a permanent and general character are not now considered in the Committee of Ways and Means.

Petitions.—Among the duties of parliament is the receiving of petitions. A petition must be presented by a member of the House to which it is addressed. Petitions from the corporation of London are, however, presented to the House of Commons by the sheriffs at the bar, or by one sheriff, if the other be a member of the House, or unavoidably absent. In 1840, a petition was allowed to be presented by the Lord Mayor and Aldermen, when the sheriffs were in custody of the sergeant-at-arms. The Lord Mayor of Dublin has been allowed to present a petition at the bar of the House, and the same privilege would probably be conceded to the Lord Provost of Edinburgh. Petitions which violate any of the rules of the House, are not brought up, but returned to the petitioners; and if an irregularity be discovered after a petition is brought up, its presentation is not recorded in the votes.

In the House of Lords, when a petition is laid on the table, an entry is made in the Lords' Minutes, and afterwards in the Journals of the House, which, however, does not describe its nature and substance. A petition may, on presentation, be made a subject of debate, but unless this is done, there remains no public record of its import, or of the parties by whom it was signed. In the House of Commons, according to standing orders adopted in 1842, the member presenting a petition is to confine himself to a statement of who the petitioners are, the number of signatures, the material allegations of the petition and its prayer. In case of urgency, or where questions of privilege are involved, the matter of the petition may be discussed; but in ordinary cases no debate is allowed, and it is referred to the Committee on Public Petitions, and if relating to a subject with regard to which the member presenting it has given notice of a motion, it may be ordered to be printed with the votes. The reports of the Committee on Public Petitions are printed twice a week, and point out the name, the subject, and the number of signatures of each petition, and the total number of signatures, and petitions relating to each subject; and, in some cases, the petition itself is printed at full length in the appendix.

Communications with the Crown.—Besides at the opening and proroguing of parliament, and giving of the royal assent, there are other occasions on which the crown communicates with parliament by a *message*, under the sign-manual, to either House singly, or both Houses separately. Messages are brought by a member of the House, being a minister of the crown or one of the royal household, and may relate to important public events, the prerogatives or property of the crown, provision for the royal family, &c. An *address* is the mode in which the resolutions of parliament are communicated to the crown. Addresses may be joint, of both Houses, or separate, of either House.

Returns.—Each House has the power of ordering returns from all those public departments which are connected with the revenue, under control of the Treasury, or regulated by statute; but returns of matters connected with the exercise of royal prerogative, as from public departments subject to her Majesty's secretaries of state, are obtained by means of addresses to the crown. A return is not allowed to be ordered in one House regarding the proceedings of the other; when such return is wished, it is usual to make an arrangement by which it is moved in the House to whose proceedings it relates, and after it has been presented, a message is sent to request that it may be communicated. Returns cannot be moved from private associations, or persons not exer-

cising public functions; and the papers and correspondence sought from government departments must be of an official, not a private or confidential description. This rule was, under special circumstances, departed from in 1858, in regard to the opinion of the law-officers of the crown in the case of the *Cagliari*. Accounts and papers presented are ordered to lie on the table, and when necessary, ordered to be printed, or in the Commons referred to the Printing Committee appointed at the beginning of each session.

Election Petitions.—Until 1770 all questions regarding controverted elections were decided by the whole House; the Grenville Act of that year introduced the practice of appointing committees for their trial, and the proceedings of election committees were further regulated by 11 and 12 Vict. c. 98. By the 'Parliamentary Elections Act, 1868' (31 and 32 Vict. c. 124), election petitions are now presented to the Court of Common Pleas in Westminster or Dublin, or the Court of Session in Scotland, and tried by a single judge appointed by the court, and sitting in the borough or county whose election is contested. An election petition must be signed by some person who voted, or had a right to vote at the election, or by some person who claims to be returned, or alleges himself to have been a candidate, and presented within twenty-one days after the return objected to, or if it proceeds on the allegation of bribery, within 28 days after the alleged payment. Security is to be found for costs to the extent of £1000, either by sureties not exceeding four, or by a deposit of money, or partly in each way. The judge determines whether the member was duly elected, and certifies to the Speaker his determination, which is final. Should the petition allege corrupt practices, the judge shall also report to the Speaker whether there has been any corrupt practice within the knowledge and consent of any candidate, the names of persons proved guilty, and whether corrupt practices have prevailed extensively at the election: also the judge may specially report any matter for consideration of the House of Commons. Where, on application of any party to a petition, it appears that the case raised can be conveniently stated as a special case, it may be so stated and determined by the court, who certify their decision to the Speaker, which is final.

An election petition cannot be withdrawn without leave of the court or judge on special application: and a person who might have been a petitioner may apply to be substituted for the person withdrawn. The court or judge is to report to the Speaker whether in their opinion the withdrawal of the petition has been induced by any corrupt arrangement. The most frequent subjects of special reports are bribery, treating, and the use of undue influence, matters regarding which, prior to 1868, various acts had been passed, the most important being those of 1854, of 1858, of 1868, of 1879, and of 1882 (see also the article **BRIBERY**), statutes generally known by the name, the 'Corrupt Practices Prevention Acts.' By the act of 1868, a candidate convicted of bribery is punished by voidance of his election, incapacity during 7 years to be elected or to vote, to hold any office under 5 and 6 Will. IV. c. 78, or 3 and 4 Vict. c. 103, or any municipal or judicial office, or to act as justice of the peace; and the same disqualifications to vote, to be elected, and to hold office, are incurred by any person other than a candidate found guilty of bribery. If a candidate is proved to have knowingly engaged as canvasser or election-agent a person found guilty within the previous seven years of any corrupt practice, his election is void. Act 15 and 16 Vict. c. 57 enacts that upon the joint address of both Houses of Parliament, representing to her Majesty that a Committee of the House of Commons has reported that corrupt practices have extensively prevailed at any election, her Majesty may appoint commissioners to make inquiry; and by the act of 1868, the judge's report to the effect that corrupt practices have prevailed, or that there is reason to believe they have prevailed, is to be accounted equivalent to the report of the House of Commons' Committee to that effect under the previous act. It is further provided by the act of 1868 that within 21 days of the return to the Clerk of the Crown, or within 14 days after the meeting of parliament, a petition may be presented by any two electors, alleging that corrupt practices have extensively prevailed at their last election, or that there is reason to believe this to have been the case. If, on such petition, an address by both Houses of Parliament be presented to the crown, praying for inquiry into such allegation, the crown may appoint commissioners to inquire, with the powers and subject to the provisions of Act 15 and 16 Vict. c. 57.

By the Act of 1854, the offering of money, office, employment, &c., to a voter to induce him to vote or abstain from voting, or the offering of a similar consideration to any person to induce him to procure the return of a candidate or the vote of an elector, the acceptance of such consideration, and the payment of money in the knowledge that it is to be expended in bribery, or the repayment of money which has been spent in bribery, are all declared to be acts of *bribery* punishable by fine and imprisonment, as well as for the forfeiture of £100 with costs to any person who will sue for the same. Any voter who agrees to receive money, office, or employment for voting or abstaining from voting, and

any person who, after an election, receives money or other consideration on account of any person having voted or refrained from voting, is also guilty of bribery, and liable to forfeit £10 with costs to any one who will sue for the same. *Treating*, which is defined as the providing of meat, drink, or other entertainment to any person in order to be elected, or in consideration for any person voting or abstaining from voting, involves a penalty of £50 similarly recoverable, as also does *undue influence*, or interference by intimidation, abduction, or otherwise, with the freedom of electors. Persons guilty of any of these offences are, by the provisions of the same acts, to be struck off the register, and their names inserted in a separate 'list of persons disqualified for bribery, treating, and undue influence,' which is to be appended to the register of voters. Cockades are prohibited, as is the furnishing of refreshment on the day of election to a voter in consideration of his being about to vote. By the Corrupt Practices Act, 1854, it is however declared lawful to provide a conveyance for a voter, though not to pay him a sum of money for traveling expenses. By the Act of 1863, no payment is allowed to be made on behalf of a candidate except through his authorized agent, and all claims against a candidate in respect of an election must be settled within a month, otherwise the right to recover them is barred. A detailed account of election expenses with vouchers is required to be delivered within two months of the election to the returning officers, by whom it is published in a local newspaper, and the vouchers are to be open for a month to the inspection of voters. The act of 1863 provides that when an election committee has reported that certain persons named have been guilty of bribery, and their report is confirmed by a commission of inquiry, such report, with the evidence taken, is to be laid before the Attorney-general with the view of instituting a prosecution.

Impeachment.—There are instances, as far back as the times of the Plantagenet princes, of the supreme power of parliament being exercised to punish offences where something extraordinary in the nature, or some unforeseen obstacle to the execution of the ordinary laws, was deemed to render this advisable. This was done by a bill of attainder, which in the reign of Henry VIII. became the usual mode of proceeding against state offences. A bill of attainder sometimes followed a regular trial and conviction as in the case of Empson and Dudley, but was often passed without trial, examination of witnesses, or hearing the accused party, as in the attainder of Fisher and Sir Thomas More. Bills of attainder were sometimes, but rarely, had recourse to under the Stuart kings; the last instance was the case of Sir John Fenwick, in 1696. The practice of impeachment of extraordinary offenders before the Lords by the Commons, which had been frequent during the 14th and 15th centuries, was revived in the reign of James I. This proceeding is not like bills of attainder or pains and penalties, the making of a new law *pro re nata*, but a carrying out of the already known and established law. The great representative inquest of the nation first find the crime, and then as prosecutors support the charge before the highest court of criminal jurisdiction. It has always been allowed that a peer may be impeached for any crime whether cognizable by the ordinary courts or not. The right of the Commons to impeach a commoner of a capital offence, which was at one time doubted, has been solemnly affirmed by the House of Lords. The trial is conducted by managers for the Commons. Witnesses are summoned by the Lords at the desire of the Commons, and Westminster Hall has usually been the place of trial, the Lord High Steward presiding. The managers make their charges and adduce evidence; the accused answers, and may defend himself by counsel; and the managers have a right to reply.

In giving judgment, the question is put by the Lord High Steward to each peer, beginning with the junior baron, on each article separately, whether the accused be guilty. The answer is 'Guilty, on my honor,' or 'Not Guilty, on my honor,' the Lord High Steward giving his opinion the last, and the numbers being cast up, the accused is acquitted with the result. Impeachments have not been common in later times, though they are still a competent proceeding; the latest memorable cases are those of Warren Hastings in 1788, and Lord Melville in 1805.

Trial of Peers.—Peers are, in all cases, tried by their peers for treason, misprision of treason, felony, or misprision of felony. For misdemeanors, however, they are tried before the ordinary courts of law; and the Lords Spiritual are in all cases tried before the ordinary courts of the country. During the sitting of parliament, the trial proceeds before the House of Lords, or more properly before the Court of Parliament presided over by the Lord High Steward. When parliament is not sitting, the trial takes place before the Court of the Lord High Steward—a tribunal whose constitution was at one time very objectionable, that officer being allowed to summon what peers he pleased, only with the proviso that the number should amount in all to 23. Act 7 Will. III. c. 3 requires that all the peers who have a right to sit and vote in parliament be summoned. Peers of Scotland and Ireland are, in terms of the Acts of Union, tried in the same way.

By 4 and 5 Vict. c. 22, a peer is liable, on conviction to the same punishment as any other of the lieges.

New Procedure Rules.—Incessant obstruction of business in the House of Commons by the concerted action of the Irish parliamentary party, and their systematic abuse of the rules of the House, led, in 1882, to the proposal by government of a series of new rules for procedure, which were adopted after long debate. Of the thirteen resolutions passed, ten were straightway made into standing orders. Henceforth, when it appears to the Speaker or Chairman that a subject has been adequately discussed, and that this is the evident sense of the House, he may inform the House to that effect; and a motion 'that the question be now put,' shall be carried, if supported by more than 200 members, or if opposed by less than 40 and supported by more than 100. Motions for adjournment may be used for the discussion of a definite matter of urgent public importance if 40 members stand up in favor of this course. Provision is made in that case for limiting the debates to the subject in hand. Some new arrangements are made for taking divisions, and technical directions are supplied for the guidance of Speaker or Chairman. No opposed motion shall be taken after half-past twelve. Regulations are laid down for the suspension of offending members. The Speaker or Chairman is invested with large discretionary powers for checking the attempts to secure delay by abuse of the rules. At the same time, rules were adopted relating to the appointment or working of Standing Committees, or Grand Committees, as an experimental means of assisting the House to get more expeditiously through its work, which had latterly got far into arrears.

See Sir T. Erskine May's *Laus, Privileges, Proceedings, and Usage of Parliament* (new ed. 1879); Lucy's *Parliamentary Procedure* (1880); Walpole's *The History and the Legislature* (1881).

PARLIAMENTARY CHURCH is a church erected under the authority of an act of parliament. In England such a church is generally called a district church; and the acts of parliament authorizing such churches are known as the Church Building Acts. See **PARISH**. In Scotland similar churches are called *Quoad Sacra* churches.

PARMA, once a sovereign duchy of Italy, lying between the Apennines and the Po, touching Sardinia (Piedmont) in the west, and Modena on the east. It comprised, at its annexation to the kingdom of Italy, the two duchies of Parma and Piacenza; had an area of 2270 sq. m., and a pop. of 490,000. The Apennines, which cross the southern division of the duchies, send off spurs northwards; the north is an undulating plain, sloping to the Po. The highest peaks in P. are about 7000 feet high. The mountain-range is richly clad with oak and chestnut forests. The plain, which is very fertile, produces rich crops of grain (including rice), leguminous plants, fruits of all kinds, olives, and grapes; while marble, alabaster, salt, and petroleum are the chief mineral products. Agriculture, silk-working, cattle-breeding, and cheese-making are the chief employments. Silk and cheese are the chief exports. The cheese, however, known as Parmesan, is not made in P., but near Lodi (q. v.).

The form of government was monarchical, and the administrative power was in the hands of a council of state. The revenue was about £450,000.

History.—P. and Piacenza belonged in the time of the Roman Empire to Cisalpine Gaul, and after its fall came under the rule of the Lombards, to whose rule succeeded that of the kings of Italy and the German emperors. In the 12th and following centuries, they joined the other territories of Northern Italy which were struggling for liberty and independence, and consequently became involved in the Guelph and Ghibelline contests. Weakened by these strifes, they fell under the domination of the powerful houses of Este, Visconti, and Sforza; but in 1499 they passed under the yoke of the French monarch, Louis XII., from whom they were soon recovered by the Emperor Maximilian, and handed over to Pope Leo X. in 1512. They continued under the sovereignty of the popes till 1543, when they were alienated by Pope Paul III., and with the surrounding territory were erected into a duchy for his natural son Pier-Luigi Farnese, the grandfather of Alessandro Farnese, the celebrated regent of the Low Countries. On the extinction of the male line of Farnese, in 1731, by the death of the eighth duke, Antonio, his niece Elizabeth, the queen of Philip V. of Spain, obtained the duchies for her son Don Carlos, who, however, exchanged them in 1735 with Austria for the throne of the Two Sicilies. In 1748 they were restored along with Guastalla to Spain, and became a duchy for the Infante Don Philip, with a reversion to Austria in case of the failure of his male descendants, or of any of them ascending the Spanish or Neapolitan throne. Philip was succeeded in 1765 by his son Ferdinand, who was an able and enlightened ruler, and expelled the Jesuits in 1768. He died in 1802, and his dominions were immediately taken possession of by the French, and were incorporated with France under the designation of the department of *Taro* in 1805.

In 1814, by the treaty of Paris, P., Piacenza, and Guastalla were presented as a sovereign duchy to the ex-empress Maria Louisa, a proceeding strongly opposed by the king of Spain, who demanded them for his sister, Maria Louisa, the widow of Louis, king of Etruria, the son of Duke Ferdinand. However, in 1817, it was settled that Maria Louisa of Austria should possess the duchies, and that on her death they should descend to Ferdinand Charles, Duke of Lucca, the son of Maria Louisa of Spain, and the rightful heir; and on failure of his heirs, P. should revert to Austria, and Piacenza to Sardinia. On her death, in 1847, the Duke of Lucca succeeded as Charles II., and certain exchanges of territory, previously settled by the great powers, took place with Tuscany and Modena—the chief of which being the transfer of Guastalla to Modena, resulting in a gain to P. of 100 sq. m. of territory. This transfer was not made without great discontent on the part of the inhabitants. The duke's rule was severe and tyrannical, and on an address being presented to him with a view of obtaining a reform of certain abuses, and a more liberal political constitution, similar to what Tuscany had (February 1848) obtained from its grand-duke, he threw himself into the arms of Austria, and consented to the occupation of his territory by Austrian troops. In March 1848 a revolution broke out, and the duke was compelled to grant the popular demands, but he almost immediately after retired from the country.

P. joined with Sardinia in the war of 1848—1849 against Austria, but on the triumph of the latter power was compelled to receive Charles III. (his father, Charles II., having resigned his throne, March 1849) as its ruler. The new duke recalled the constitution which his father had been compelled to grant, and punished with great severity the active agents of the revolutionary movements in his dominions. His arbitrary measures were effectively seconded by his chief minister, an Englishman named Ward, who shared the public obloquy with his master. After Charles III.'s assassination in March 1854, his widow Louise-Marie-Therese de Bourbon, daughter of the last Duke of Berry (q. v.), assumed the government for the behoof of her son Robert I., and made some attempts at political reform; but owing to the excited state of the people they were little effective, and she and her son were compelled to leave the country in 1859, on the outbreak of a new war between Sardinia and Austria. In March 18th of the following year the country was annexed to Sardinia, and it now forms a part of the 'compartimento' Emilia, in the kingdom of Italy, constituting the two provinces of Parma (area 1270 sq. m.; pop. in 1881, 267,386) and Piacenza (area 910 sq. m.; pop. 225,764); a few of the outlying districts being incorporated with other provinces.

PARMA, the chief town of the province of the same name in Italy, and formerly the capital of the duchy of Parma, is situated on both sides of the river Parma, 12 miles south from the Po, 75 miles south-east from Milan, and about the same distance east-north-east from Genoa, with a population (1881) of 45,217.

The town is of a circular form, and is surrounded by walls and ditches flanked by bastions; the streets are straight and wide, and meet at right angles, the chief of them, a part of the Roman Via Emilia, crossing the city from east to west, and dividing it into two nearly equal parts. P. is celebrated for its churches, 10 in number, the chief of which are the *Duomo*, or Cathedral (consecrated 1106 A.D.), built chiefly in the Lombard style, having the interior adorned with magnificent frescoes by Correggio, and paintings by other artists, and surmounted by a beautiful dome; the *Battisterio*, or Baptistry, one of the most splendid in Italy, begun in 1196 and completed in 1281; the church of the *Madonna della Steccata*, containing the famous painting of 'Moses breaking the Tables of the Law' by Parmigianino. The other celebrated buildings are the Farnese Palace, a gloomy and ill-constructed edifice; the Farnese Theater, built (1618—1628) of wood, and now in a most dilapidated condition. P. has also a library containing 120,000 volumes, mostly well selected, and many of them rare and valuable works; a museum of antiquities; a botanic garden; a theater (*Teatro Nuovo*); an academy of fine arts, founded in 1752, possessing a collection of 600 pictures, many of which are exceedingly valuable. The pictures most highly esteemed are the 'Madonnas' of Correggio and Francis, the 'St. Jerome' of Correggio, and the 'Jesus Glorified' of Raphael.

The manufactures of P. are stockings, porcelain, sugar, wax-candles, and vessels of crystal, also silk, cotton, and fusian stuffs. The chief exports are cheese and silk goods; and in June there is an annual silk fair.

PARMA, BATTLES OF. An indecisive engagement took place here June 29, 1734, between the confederated armies of England, France, and Spain, and the Austrians; and on June 19, 1799, the French under Macdonald were routed by the Russians under Suwarof, with a loss of 10,000 men and 4 generals.

PARMELIA, a genus of Lichens, with a leafy horizontal thallus which is lobed and cut; and orbicular shields (*apothecia*) fixed by a central point, concave, and bordered by the inflexed

thallus. The species are numerous, and many are found in Britain. Some of them are occasionally employed in dyeing. Various chemical principles have been discovered in lichens of this genus, as *Usnine* or *Usnic Acid* (also found in species of the genus *Usnea*), and *Parietina*. Valuable medicinal properties—tonic and febrifugal—have been ascribed to *P. Parietina*, the Common Yellow Wall Lichen, or Common Yellow Wall Moss of the herb shops, a bright yellow species with deep orange shields, plentiful on walls and trees in Britain and most parts of Europe.

PARME'NIDÉS, a Greek philosopher of Elea, in Lower Italy, and in the opinion of the ancients the greatest member of the Eleatic school, flourished about the middle of the 5th c. B.C. Nothing is known with certainty regarding his life, but he is said to have visited Athens in his old age, and to have conversed with Socrates, then quite a youth. The story, though it rests on the authority of Plato, has a suspicious air, and seems as if it were intended to account for the influence which the philosophy of P. undoubtedly exercised on that of Socrates and Plato themselves. P., like Xenophanes of Colophon, sometimes regarded as the first of the Eleatics, expounded his philosophy in verse—his only work being a didactic poem *On Nature*. The leading design of this poem is to demonstrate the reality of Absolute Being, the non-existence of which P. declares to be inconceivable, but the nature of which, on the other hand, he admits to be equally inconceivable, inasmuch as it is dissociated from every limitation under which man thinks. P. is not a theologian in speculation, seeking rather to identify his 'Absolute Being' with 'Thought' than with a 'Deity.' Only fragments of his poem remain, which have been separately edited by Fülleborn (Züllichau, 1795); another collection is that by Brandis, in his *Commentationes Eleaticæ* (Altona, 1815); but the best is to be found in Karsten's *Philosophorum Græcorum ceterum Reliquiæ* (Amstelod, 1835).

PARMIGIANO, GIROLAMO FRANCESCO MARIA MAZZOLA, called Parmigiano or Parmigianino, born at Parma in 1503, an able painter of the Lombard school, and the most distinguished of those who followed the style of Correggio. His pictures attracted much attention when he was little more than fourteen years of age. In 1523 he went to Rome to follow out his studies, and was soon favorably noticed and employed by Clement VII. He was in that city when it was stormed by the imperialists under Bourbon in 1527, and, it is said, was calmly at work on his picture of 'The Vision of St. Jerome' (now in the National Gallery, London) when soldiers, bent on pillage, burst into his studio. He was, however, protected by their leader. After this event he left Rome for Bologna, where he painted various important works, and returned to Parma in 1531. Having engaged to execute several extensive frescoes in the church of S. Maria Steccata, after repeated delays, he was thrown into prison for breach of contract, and on being released, in place of carrying out his undertaking, he fled to Casal Maggiore, in the territory of Cremona, where he died soon afterwards in 1540. Vasari, in his notice of P., attributes his misfortunes and premature death to his passion for alchemy; but this oft-repeated story has been disproved by the researches of late biographers. He executed several etchings, and some wood-cuts are attributed to him.

PARNAHI'BA, or PARANAHYBA, a river of Brazil, rises in the Sierra dos Coroados, between the provinces of Goyas and Piauhí, about 11° S. It flows north-east and north, and enters the Atlantic in long. about 41° 40' W. by five mouths, which enclose a delta about 30 miles wide along the shore. These mouths, however, are only from two to four fathoms deep. It drains the province of Piauhí, and forms the boundary-line between it and the province of Maranhão. Total length estimated at 750 miles.—A chief tributary of the Parana also bears the name of Parnahiba.

PARNA'SSUS, a mountain greatly celebrated among the ancients, and regarded by the Greeks as the central point of their country. It was in Phocis. It has three steep peaks, almost always covered with snow, and seen from a great distance, the highest being fully 8000 feet above the level of the sea; but as only two of them are visible from Delphi, it was customary among the Greeks to speak of the two-peaked Parnassus. On its southern slope lay Delphi (q. v.), the seat of the famous oracle, and the fountain of Castalia (q. v.). The highest peak was the scene of the orgies of the worship of Dionysus (Bacchus); all the rest of the mountain was sacred to Apollo and the Muses, whence poets were said to 'climb Parnassus,' a phrase still thus employed.

PARO'CHIAL BOARD, in Scotland, is the board in each parish which manages the relief of the poor. In England, the same duty is performed by overseers, and in some cases by guardians of the poor.

PAROCHIAL RELIEF is the relief given to paupers by the parish authorities. See POOR.

PA'RODY (Gr. *para*, beside, and *ode*, a song) the name given to a burlesque imitation of a serious poem. Its peculiarity is that

it preserves the form, and as far as possible the words of the original, and thereby differs from a Travesty, which is a looser and less literal kind of burlesque. The invention of parodies is commonly ascribed to the Greeks (from whom, at least, we have derived the name); the first parodist, according to Aristotle, being Hegemon of Thasos, who flourished during the Peloponnesian war, according to others, Hipponax. From the fragments that are extant of ancient parody, we infer that Homer was the favorite subject of comic imitation. Thus Hipponax, in his picture of a glutton, ludicrously insinuates a comparison between the feats of his hero in eating and those of Achilles in fighting, by commencing as follows:

Sing, O celestial goddess, Enrymedon, foremost of gluttons,
Whose stomach devours like Charybdis, eater unmatched among mortals.

The *Batrachomyomachia* (Battle of the Frogs and Mice), erroneously ascribed to Homer, is also a happy and harmless specimen of the parody, which, however, soon began to exchange its jocose and inoffensive railery for a biting and sarcastic banter, of which numerous specimens may be seen in the comedies of Aristophanes; while the philosopher Timon of Phlius invented, under the name of *Silla*, a new species of satirical parody. Among the Romans we first meet with this form of literature in the period of the decline. All the power of Nero could not prevent his verses from being parodied by Persius. Among modern nations the French—as might naturally be expected from their character—have been most addicted to this literary mimicry. Corneille parodied Chapelein in his *Cid*, and Racine parodied Corneille. The *potpourris* of Désangiers are considered by his countrymen models of this ungracious kind of literature. Schiller's famous poem of the *Bell* has been often parodied by German wits. In England, perhaps the best compositions of this nature are the *Rejected Addresses* of the brothers James and Horace Smith. Many will remember, in particular, the parody on Scott's 'Battle of Flodden' in *Marmion*, ending—

'od rot 'em
Were the last words of Higginbotham.

Barham's *Inglotsby Legends* contains a felicitous parody on Wolfe's *Lines on the Burial of Sir John Moore*. We quote the first stanza as a specimen:

Not a sou had he got, not a guinea or note,
And he looked most comfoundedly flurried
As he bolted away without paying his shot,
And his landlady after him hurried.

The *Verses and Translations* and the *Fly-Leaves* of C. S. Calverley contain clever parodies of the style of our modern poets. Thackeray's *Miscellanies* and Bret Harte's *Condensed Novels* also contain some very clever and satirical prose parodies upon certain of their brother novelists.

See Moser in Daub's and Creuzer's *Studien*; also Moser's *Parodiarum Exempla*.

PARO'LE (literally, a word) is the declaration made on honor by an officer, in a case in which there is no more than his sense of honor to restrain him from breaking his word. Thus a prisoner of war may be released from actual prison on his parole that he will not go beyond certain designated limits; or he may even be allowed to return to his own country on his parole not to fight again, during the existing war, against his captors. To break *parole* is accounted infamous in all civilized nations, and an officer who has so far forgotten his position as a gentleman ceases to have any claim to the treatment of an honorable man, nor can he expect quarter should he again fall into the hands of the enemy he has deceived.

PAROLE EVIDENCE, in Law, means such evidence as is given by witnesses by word of mouth at a trial or hearing of a cause. Parole Agreement, in English Law, means any agreement made either by word of mouth or by writing not under seal. If the agreement is made by writing under seal, it is called a deed, or indenture, or covenant, according to the nature of its contents.

PAROPAMISA'N MOUNTAINS. See AFGHANISTAN.

PA'ROS, one of the larger islands of the Grecian Archipelago, is situated west of Naxos, from which it is separated by a channel from four to six miles wide. Greatest length 15 miles; greatest breadth, 9 miles; area about 95 square miles; pop. 6000. The surface is hilly, the scenery picturesque, and the soil naturally fertile, but imperfectly cultivated. The island is especially productive in cotton, wax, honey, partridges and wild pigeons. Near the middle of the island, the mountain Capresso (ancient *Marpessa*), abounds in the famous Parian marble, which was used by many of the greatest sculptors of antiquity. Parekhia on the west coast, is the principal town, and Naussa, on the north coast, is the chief port.

In ancient times, P., which is said to have been colonized by Cretans, attained great maritime prosperity, and became wealthy

and powerful. It submitted to the Persians; and after the battle of Marathon was assailed ineffectually by Miltiades, who received here the wound of which he soon after died. After the defeat of Xerxes, P. came under the supremacy of Athens, and shared the fate of the other Cyclades. Archilochus, the inventor of Iambic verse, was born here.

PARO'TID GLAND. See **SALIVARY GLANDS.**

PARQUETRY, a kind of wood mosaic used only for flooring. The art of making inlaid wood floors has until lately much declined in this country, but on the continent it has been much in use, and has been carried to great perfection. Parquetry floors are usually of oak, but other and more ornamental woods have also been much used for giving variety and beauty to the pattern. In the more elaborate kinds of parquetry, veneers are used, but it is much more generally composed of blocks of wood squared at the sides, and laid down so as to combine and form a geometric pattern. Of late, the taste for this work has revived in Britain, and it is beginning to be extensively employed in the better class of buildings.

PARR, SAMUEL, LL.D., a once notable scholar, was born January 15, 1747, at Harrow-on-the-Hill. He entered Emmanuel College, Cambridge, in 1765; but the death of his father, two years afterwards, necessitated his doing something for himself, and he was, in consequence, induced to accept an assistant-mastership at Harrow, where he remained five years. The head-mastership then becoming vacant, P. applied for it, but was rejected, whereupon he left, and started as an independent school-master. In 1777, he was appointed Master of Colchester School, where he was ordained priest, and obtained the curacies of Hythe and Trinity Church.

Next year, he became Master of Norwich School; but in 1786, settled at Hatton in Warwickshire, where he spent the rest of his life. In 1787, he published an edition of Bellenden, to which he prefixed his celebrated preface, which is as remarkable for its uncompromising advocacy of Whig principles as for the scrupulous Ciceronianism of its Latinity. He died March 6, 1825.

It is almost impossible to understand the reputation which P. once had. None of his voluminous writings justify it. That he was in some respects an accomplished, and even a great scholar, is undoubted, for he could write Latin of Ciceronian purity and finish; but it is equally undoubted that he never did anything with his boasted scholarship. P. has left the world absolutely nothing to keep it in remembrance of him, yet his complete works (edited by Dr. J. Johnstone in 1828)—exclusive of his contributions to periodicals—form eight enormous tomes, and contain 5734 octavo pages, many of them printed in small type. They relate to matters historical, critical, and metaphysical, but in all of them 'the thread of Parr's verbosity is finer than the staple of his argument.' What, then, gave him the fame that he certainly enjoyed during his life? Beyond all question, it was his conversational powers. He was an amazing, an overwhelming talker. Bold, dogmatic, arrogant, with a memory profoundly and minutely retentive, and with a genuine gift of ephemeral epigram, he seemed, at the tables of statesmen, and wits, and divines, to be a man of tremendous talent, capable of any literary feat; but the learning and the repartee have left little trace of their existence, and posterity declines to admire the wonders that it has neither seen nor heard. See De Quincey's famous essay on 'Dr. Samuel Parr on Whiggism in its Relations to Literature' (Author's edition, vol. 5. Edin. Adam and Charles Black, 1862).

PA'RRÁ. See **JACANA.**

PARRAKEE'T, or **PAROQUET**, a name very commonly given to many of the smaller species of the parrot family; generally to species having long tails, and natives of the East Indies, Africa, and Australia, not so frequently to American species; although it is sometimes also applied to some of these, indifferently with the name Parrot.—One of the most beautiful groups of the *Psittacidae*, combining gracefulness of form with splendor of plumage, is that to which the **ALEXANDRINA P.** or **RING P.** (*Palaeornis Alexandri*) belongs. It is about the size of a common pigeon, green, with a red collar, whence its name Ring P., and is a native of the East Indies. It is said to have been brought to Europe by some of the members of Alexander the Great's expedition to India, and to have been the first of the parrot tribe known to the Greeks and Romans, by whom it was highly prized, as it still is, not only for its beauty, but for its docility and its power of imitating human speech. Like many of its tribe, it is gregarious, and immense flocks make their abode in some of the coconut groves of the western part of Ceylon, filling the air with the most deafening screams. The Ring P. has many congeners, natives chiefly of the East Indies, exhibiting much variety of splendid plumage.—Somewhat like them in length and form of tail, but with longer and stronger legs, is the **GROUND P.**, or **GROUND PARROT** (*Peophorus formosus*), of Australia, a bird once common in the southern parts of Australia and in Tasmania; but now

nearly exterminated by cats run wild, which infest the scrubs. Its habits are very unlike those of parrots in general; it runs along the ground, and even seeks to escape from enemies by running, unwillingly takes wing, and then only for a short low flight. It makes no nest, but lays its eggs in a hole in the ground. It is a small bird, not much more than 12 inches in

Warbling Grass or Zebra Parrakeet (*Melopsittacus undulatus*).

entire length, one half of which is occupied by the tail; its color, dark green above, yellowish below, less brilliant than in many of the parrot tribe, but finely marked and mottled. Its flesh has a very strong game flavor.

There are numerous other Australian species; distributed in several genera, some of which, although less exclusively than that just noticed, live and seek their food on the ground. Some of them exhibit the greatest splendor of plumage. The only one we shall notice is the **ZEBRA P.** (*Melopsittacus undulatus*) a very beautiful little species, which has often been brought to England, and has sometimes bred in it. In the vast inland plains of Australia, this P. is to be seen in flocks of many hundreds feeding on the seeds of the grasses, which afford food also to many other small species.

PA'RRAS, a well-built town of Mexico, in the state of Coahuila 470 miles north-west of Mexico, near the east shore of Lake Parras. Pop. 8000.

PARRHASIUS, one of the greatest painters of ancient Greece, was the son of Evenor, himself an artist, and was born at Ephesus in the 5th c. B.C. He practised his profession, however, at Athens, the inhabitants of which held him in high estimation, and conferred on him the rights of citizenship. He was already celebrated in the time of Socrates, with whom, according to Xenophon, he held a conversation (*Mem.* 3, 10), and was also a younger contemporary of Zeuxis. The date of his death is unknown. Seneca, who lived several hundred years after, tells a monstrous story about him. He says that when P. was painting his 'Prometheus Vincens,' he got hold of one of the prisoners taken at the capture of Olynthus by Philip of Macedon (347 B.C.), and crucified him in his studio that he might copy from life the expression of agony. Fortunately for P.'s memory, the anecdote is almost certainly untrue, as it would require us to suppose that he was still alive and painting when upwards of 100 years old. P. appears to have surpassed all his predecessors in purity of design, accuracy of drawing, force of expression, and what is technically called 'finish.'

According to Pliny, he was the first who established a true proportion between the different parts of a picture, and delineated with elegance and precision all the minutiae of the features, even to those evanescent motions that betray the most delicate sentiments of the soul. He painted the extremities, such as the hands and fingers, in so exquisite a style, that the intermediate parts seemed relatively—but only relatively—inferior. Quintilian calls him the legislator of his art, because his canon of proportion for gods and heroes was followed by all contemporary and subsequent painters. Among his works were an apparently symbolical picture of the Athenian *Demos* ('People'), a 'Thesens,' 'Naval Commander in full Armor,' 'Ulysses feigning Madness,' 'Castor and Pollux,' 'Bacchus and Virtue,' a 'Meleager, Hercules, and Perseus' on one canvas, a 'Cretan Nurse with a Child in her Arms,' a 'Priest officiating with a Child bearing Incense,' 'Two Young Children,' an 'Achilles,' an 'Agamemnon,' &c. But his subjects

were not always of a pure or lofty character. His 'Archigallus' (high-priest of Cybele) and his 'Meleager and Atalanta' were most licentious representations, and gave such pleasure to the Emperor Tiberius, a man of unbounded sensuality, that he kept them in his bedroom, and valued the second in particular at more than a million sesterces.

P. was of an excessively proud and arrogant disposition. He called himself the prince of painters, and claimed to be descended from Apollo; he also painted himself as the god Mercury, and then exposed his own portrait for the adoration of the crowd. His vanity was equal to his pride, and showed itself even in his apparel, which was of the kind called 'gorgeous.' He generally dressed in a purple robe with a golden fringe, sported a gold-headed cane, and wore boots tied with golden clasps.

PA'RRICIDE (Lat. *paricida*) is rather a popular than a legal term. In the Roman law it comprehended every one who murdered a near relative; but in English the term is usually confined to the murderer of one's father, or of one who is *in loco parentis*. The parricide does not, in any respect, differ in Britain, from the murderer of a stranger; in both cases, the punishment is death by hanging. In the Roman law, a parricide was punished in a much more severe manner, being sewed up in a leather sack, along with a live cock, viper, dog, and ape, and cast into the sea to take his fate with these companions.

PARRISH'S CHEMICAL FOOD is the popular name for a non-official preparation medicinally known as *Compound Syrup of Phosphate of Iron*, every drachm of which contains 1 grain of phosphate of iron, 2½ of phosphate of lime, besides soda and potash. Mr. Parrish of Philadelphia was the first to publish a formula for this very useful compound.

PARROT (*Psittacus*), a Linnæan genus of birds, now the family *Psittacidae*, of the order *Scansores*, or Climbers (q. v.), comprehending a vast number of species, natives of almost all tropical and subtropical regions; a few species extending further north and south, in America, in New Zealand, and in Tasmania. They are mostly birds of splendid plumage; they vary very much in size, from the Great Macaw, more than three feet in length, tail included, to the little Love-birds, not larger than sparrows. They are mostly gregarious, and are often seen in vast flocks, generally inhabiting forests, and making their nests in trees, feeding chiefly on fruits and seeds, partly also on leaves and buds; but some of them live in open plains, feeding on the seeds of grasses and other plants, bulbs, and succulent parts of vegetables. The *Kea* or Mountain Nestor, a New Zealand parrot, has of late taken to attacking sheep and devouring the flesh of living animals, to the great damage of the flocks.

The voices of the P. tribe are generally harsh and discordant, although some of the smaller kinds have not unpleasant voices; but many of the larger have a remarkable power of imitating human speech, and in domestication become capable of articulating not only words but sentences. They exhibit a greater degree of intelligence than is usual in birds, with a monkey-like restlessness and love of trick; and although docile and affectionate, are generally of capricious irritable temper. They have a short, stout, hard beak, rounded on all sides, and enveloped at the base in a membrane in which the nostrils are pierced; the upper mandible generally much longer than the lower, much curved, and sharp pointed. The tongue is almost always very large, thick, round, and fleshy; the muscles which move the mandibles are more numerous and powerful than in most other birds. They make use of the powerful hooked bill as well as of the feet in climbing trees; and employ their feet as hands for holding their food, and bringing it up to the mouth. Their feet differ from those of all the other climbers, in being covered with small tubercle-like scales instead of plates. Some have short and some have long tails. Most of them have short wings. Their intestines are very long and slender, and without coeca.

The *Psittacidae* are easily distinguished from all other birds; but their division into distinct subordinate groups has not been found so easy. Whilst the name P. popularly includes all, except that it is seldom given to some of the smallest species, some are known by the names Macaw, Cockatoo, Parrakeet, Lory, Love-bird, &c. See these heads. But some of these names are very vaguely applied. And although the P. family is regarded as consisting of a number of very natural groups, the characters and limits of these groups have not yet been very well defined.

The name P., in its most restricted sense, is sometimes applied only to those species which have the upper mandible very distinctly toothed, the lower mandible longer than it is high; and the tail short, and square or rounded; but this use is rather ornithological than popular, the most restricted popular use equally including long-tailed species, such as the Caroline P., which are ornithologically ranked with the macaws.—The CAROLINE P. (*Conurus Carolinensis*) is the species of which the northern range extends far beyond all others of its tribe to the shores of Lake Michigan; although by the increase of cultivation, and the war

waged against these birds for their depredations on orchards and corn-rieks, their numbers have been greatly diminished in regions where they were once plentiful. Its whole length is about 14 inches, of which about one half is occupied by the tail; the general color is green, shaded with blue, and diversified with orange, the wing primaries almost black. It is gregarious, prefers to roost in the holes of hollow trees, and in such situations also the females lay their eggs. It seems to love salt, frequenting salt licks like pigeons. It is easily tamed, but does not acquire the power of articulation.—Of the short-tailed parrots, one of the best known is the GRAY P. (*Psittacus erythacus*), a West African species, about the size of a small pigeon, of an ash-gray color, with a crimson tail. It is famous for its docility, its power of articulation and of imitating noises of all kinds, its loquacity, and its mischievousness. It is very often brought to Europe, and often lives to a great age in confinement. Individuals have been known to attain the age of nearly 100 years.—The GREEN PARROTS (*Chrysotis*), natives of the tropical parts of South America, are also among the short-tailed parrots most frequently seen in Britain.

PARROT-FISH (*Scarus*), a genus of fishes of the family *Labridæ* (q. v.) or *Cyclo-Labridæ*, of oblong and massive form, with large scales, and remarkable for the structure of their jaws and teeth, the jaws being divided into halves by a median suture, the teeth incorporated with the bone in crowded quincuncial order, the surface even and polished in some species and rough in others, the oldest teeth forming the trenchant border of the jaw, and being succeeded by others as they are worn away, whilst new ones are formed behind. The species are numerous. Some of them feed on fuci, and some on corals, the younger branches of

Parrot-fish (*Scarus harid*).

which they crush, so that the animal part affords them nourishment, whilst the calcareous part is rejected. They are fishes generally of brilliant colors, some of them of wonderful splendor, and have received the name parrot-fish partly on this account, and partly on account of a fancied resemblance in their jaws to a parrot's bill. Most of them are natives of tropical seas. One species is found in the Mediterranean (*S. Oreticus*), the *Scarus* of the ancients, of which many wonderful stories were told, as to its love, its wisdom, its ruminating, its emitting of sounds, &c., and which was esteemed the most savory and delicate of all fishes. It is still held in high esteem for the table. The Greeks cook it with a sauce made of its own liver and intestines.

PARRY, SIR WILLIAM EDWARD, commonly known as SIR EDWARD PARRY, a celebrated English navigator, was born at Bath, 19th December 1790. His father, who was a physician of some eminence, destined him for the medical profession; but acting on the advice of a friend entered him as a first-class volunteer on board the *Ville-de-Paris*, the flag-ship of the channel fleet, in 1808. After several years' service, he received his commission as lieutenant, January 6, 1810. Though thus early engaged in active service, his education had not been neglected; he had attained at school to considerable eminence in classical knowledge; and for the first five years after entering the navy, he had particularly studied French and mathematics under the chaplain's superintendence, after which he constantly employed his leisure time in nautical and astronomical studies. In February 1810, he was sent to the Arctic regions in command of a ship, for the purpose of protecting the British whale fisheries and improving the admiralty charts of those regions; but in 1813, he was recalled and despatched to join the fleet then blockading the coast of the United States. He remained on the North American station till the spring of 1817, and during this time he wrote and distributed MS. copies of a work entitled *Nautical Astronomy by Night*, in which rules were given for determining accurately the altitude of the pole by observations of the fixed stars. This work he subsequently published in London. Having returned to England too late to take part in the African exploring expedition, he was, at his urgent request, backed by the recommendations of Mr. Barrow, secretary to the Admiralty, appointed to the command of the *Alexander*, under the orders of Captain John Ross in the

Isabella, and despatched in search of the 'North-West Passage' (q. v.) in April 1818. The expedition returned to England, having made no important discoveries.

The admiralty were dissatisfied with the report of Captain Ross; and P.'s opinion, though only communicated to his private friends, having become known to them, he was again sent out (May 1819), and this time commenced that career of discovery (see NORTH-WEST PASSAGE) which has immortalized him as the greatest of all Arctic explorers. P. on his return to Britain was hailed with the utmost enthusiasm, and was made commander (4th November 1820) and a member of the Royal Society. He subsequently made a second and a third voyage to the same regions, but effected nothing of importance. P. now devoted himself to the discharge of his duties as hydrographer, but such labors were too monotonous for one of his temperament, and he accordingly prepared a plan of an expedition for reaching the north pole, which being submitted to the admiralty and approved of by them, his old ship the *Hecla* was fitted out for a polar expedition, and P. set sail in her, accompanied by Lieutenant J. C. Ross, 4th April 1827. See POLAR VOYAGES. The *Journals* of these voyages were published by order of the admiralty.

P.'s career as an explorer was now closed, and he again returned to his duties as hydrographer, but his health now gave way under this sedentary mode of life, and he exchanged his office for that of commissioner to the Agricultural Company of Australia, for which country he sailed 20th July 1829. He returned to England in November 1834, and filled in succession various government appointments up till December 1846, when he retired from active service, receiving a sinecure office. On 4th June 1852 he was raised to the rank of Rear-admiral of the White, and in the following year was appointed lieutenant-governor of Greenwich Hospital—an office which he held till his death, 7th July 1855, at Ems in Germany, whither he had gone for the benefit of his health. A complete edition of his voyages was published in 1833 (Lond. 5 vols.). His life has been written by his son, the Rev. Edward Parry, M.A. of Balliol College, Oxford (1857).

PA'RSEES (People of Pars or Fars, i. e., ancient Persia) is the name of the small remnant of the followers of the ancient Persian religion, as reformed by Zerdusht, or Zoroaster, as he is commonly called. They are also known under the denomination of Guebres, under which head some account will be found respecting their recent history and present numbers. The pre-Zoroastrian phase or phases of their primeval religion will probably for ever remain shrouded in deep obscurity; so much, however, is fully established by recent investigations, that this, and what afterwards became the Brahmanic religion, were originally identical; that in consequence of certain social and political conflicts between the Iranians and the Aryans, who afterwards peopled Hindustan Proper, an undying feud arose, in the course of which the former forswore even the hitherto common faith, and established a counter faith (Ahura), a principal dogma of which was the transformation of the ancient, now hostile, gods into demons, and the branding of the entire Deva religion as a source of all mischief and wickedness. Zerdusht, the prophet, whose era is given very differently by ancient writers and by modern investigators, placed variously between 500 or 600 B.C. (Röth) and 1200 B.C. (Haug), had, like all prophets and reformers, many predecessors, chiefly among the Soshyantos or Fire-priests (Atharvans); yet to him belongs the decisive act of separating for ever the contending parties, and of establishing a new community with a new faith—the Mazdayasna or Parsee religion proper, which absorbed the old Ahura religion of the fire-priests. Referring for a summary of what is known and speculated about the person of the great reformer to the article under his name, we shall here confine ourselves to pointing out, as the characteristics of his leading doctrines, that the principle of his theology was as pure a Monotheism as ever the followers of the Jehovistic faith were enjoined. He taught the existence of but one deity, the Ahura, who is called Mazdaô (see ORMUZD), the creator of all things, to whom all good things, spiritual and worldly, belong.

The principle of his speculative philosophy is dualism, i. e., the supposition of two primeval causes of the real and intellectual world; the Vohu Manô, the Good Mind or Reality (Gaya), and the Akem Manô, or the Naught Mind, or Non-reality (Ajyâit); while the principle of his moral philosophy is the triad of Thought, Word, and Deed. Not long, however, did the pure idea of Monotheism prevail. The two sides of Ahura Mazdaô's being were taken to be two distinct personages—God and Devil—and they each took their due places in the Parsee pantheon in the course of time:—chiefly through the influence of the sect of the Zendiks, or followers of the Zend, i. e., Interpretation. According to Zerdusht, there are two intellects, as there are two lives—one mental and one bodily; and, again, there must be distinguished an earthly and a future life. The immortality of souls was taught long before the Semites had adopted this belief. There are two abodes for the departed—Heaven (Garô-Demâna, the House of the

Angels' Hymus, Yazna, xxviii. 10; xxxiv. 2; cf. Is. vi., Revelat., &c.) and Hell (Drâjoô-Demâna, the residence of devils and the priests of the Deva religion). Between the two there is the Bridge of the Gatherer or Judge, which the souls of the pious alone can pass. There will be a general resurrection, which is to precede the last judgment, to foretell which Sôsiosh (Soskyans), the son of Zerdusht, spiritually begotten (by later priests divided into three persons), will be sent by Ahuramazdaô. The world, which by that time will be utterly steeped in wretchedness, darkness, and sin, will then be renewed; death, the archfiend of creation, will be slain, and life will be everlasting and holy. These are the outlines of the Zoroastrian creed, as it flourished up to the time of Alexander the Great, throughout ancient Irania, including Upper Tibet, Cabulistan, Sogdiana, Bactriana, Media, Persis, &c.; and it is curious to speculate on the consequences which might have followed Marathon and Salamis had the Persians been victorious.

The religion of Ormuzd would have dethroned the Olympians, as it dethroned the gods of the Assyrians and Babylonians; and it would certainly have left its traces upon the whole civilized world unto this day in a much more direct and palpable shape than it now does. From the death of Alexander, however, it gradually lost ground, and rapidly declined under his successors, until, in the time of Alexander Severus, Ardshir 'Arianos' (cf. Mirkhond ap. de Sacy, *Mémoires sur div. Aut. de la Perse*, &c., p. 59), the son of Babegan, called by the Greeks and Romans Artaxerxes or Artaxares, who claimed descent from the ancient royal lineage of Persia, took the field against Artabanus, and slew him (225), thus putting an end to the four hundred years' rule of the Partians, and founded the Sassanide dynasty. This he effected in conjunction with the national Persians, who hated the 'semi-Greek' dynasty of the Arsacide, their leaning to the foreign, and contempt for the Zend religion, and finally for their powerlessness against the spreading conquests of the Romans. The first act of the new king was the general and complete restoration of the partly lost, partly forgotten books of Zerdusht, which he effected, it is related, chiefly through the inspiration of a Magian Sage, chosen out of 40,000 Magians. The sacred volumes were translated out of the original Zend into the vernacular, and disseminated among the people at large, and fire temples were reared throughout the length and the breadth of the land. The Magi or priests were all-powerful, and their hatred was directed principally against the Greeks. 'Far too long,' wrote Ardshir, the king, to all the provinces of the Persian empire, 'for more than five hundred years, has the poison of Aristotle spread.' The fanaticism of the priests often also found vent against Christians and Jews. The latter have left us some account of the tyranny and oppression to which they as unbelievers were exposed—such as the prohibition of fire and light in their houses on Persian fast-days, of the slaughter of animals, the baths of purification, and the burial of the dead according to the Jewish rites—prohibitions only to be bought off by heavy bribes. In return, the Magi were cordially hated by the Jews, and remain branded in their writings by the title of demons of hell (*Kidushin*, 72 a.).

To accept the instruction of a Magian is pronounced by a Jewish sage to be an offence worthy of death (*Shabb*. 75 a.; 156 b.). This mutual animosity does not, however, appear to have long continued, since in subsequent times we frequently find Jewish sages (Samuel the Arian, &c.) on terms of friendship and confidence with the later Sassanide kings (cf. Moed Katan, 26 a. &c.). From the period of its re-establishment, the Zoroastrian religion flourished uninterrupted for about 400 years, till in 651, A. D., at the great battle of Nahavand (near Ecbatana), the Persian army, under Yezdezhird, was routed by the Calif Omar. The subsequent fate of those that remained faithful to the creed of their fathers has been described, as we said before, under GUEBRES. At present, some remnants inhabit Yezd and Kirmân, on the ancient soil of their race; others, who preferred emigration to the endless tribulations inflicted upon them by the conquering race, found a resting-place along the western coast of India, chiefly at Bombay, Surat, Nawsari, Achmedâbâd, and the vicinity where they now live under English rule, and are recognized as one of the most respectable and thriving sections of the community, being for the most part merchants and landed proprietors. They bear, equally with their poorer brethren in Persia, with whom they have of late renewed some slight intercourse for religious and other purposes—such as their Rivâyets or correspondences on important and obscure doctrinal points—the very highest character for honesty, industry, and peacefulness, while their benevolence, intelligence, and magnificence outvies that of most of their European fellow-subjects. Their general appearance is to a certain degree prepossessing, and many of their women are strikingly beautiful. In all civil matters they are subject to the laws of the country they inhabit; and its language is also theirs, except in the ritual of their religion, when the holy language of Zend is used by the priests, who, as a rule, have no more knowledge of it than the laity.

We have spoken of the leading fundamental doctrines as laid down by their prophet. Respecting the practical side of their religion, we cannot here enter into a detailed description of their very copious rituals, which have partly found their way into other creeds.

Suffice it to mention the following few points. They do not eat anything cooked by a person of another religion; they also object to beef, pork, especially to ham. Marriages can only be contracted with persons of their own caste and creed. Polygamy, except after nine years of sterility and divorce, is forbidden. Fornication and adultery are punishable with death. Their dead are not buried, but exposed on an iron grating in the Dokhma, or Tower of Silence, to the fowls of the air; to the dew, and to the sun, until the flesh has disappeared, and the bleaching bones fall through into a pit beneath, from which they are afterwards removed to a subterranean cavern.

Ahuramazdao being the origin of light, his symbol is the sun, with the moon and the planets, and in default of them the fire, and the believer is enjoined to face a luminous object during his prayers. Hence, also, the temples and altars must for ever be fed with the holy fire, brought down, according to tradition, from heaven, and the sully of whose flame is punishable with death. The priests themselves approach it only with a half-mask (Penom) over the face, lest their breath should defile it, and never touch it with their hands, but with holy instruments. The fires are of five kinds; but however great the awe felt by Parsees with respect to fire and light (they are the only eastern nation who abstain from smoking), yet they never consider these, as we said before, as anything but emblems of Divinity.

There are also five kinds of 'Sacrifice,' which term, however, is rather to be understood in the sense of a sacred action. These are—the slaughtering of animals for public or private solemnities; prayer; the Daruns sacrament, which, with its consecrated bread and wine in honor of the primeval founder of the law, Hom or Heomoh (the Sanser. *Soma*), and Dahman, the personified blessing, bears a striking outward resemblance to the sacrament of the Lord's Supper; the sacrifice of Expiation, consisting either in flagellation, or in gifts to the priest; and, lastly, the sacrifice for the souls of the dead. The purification of physical and moral impurities is effected, in the first place, by cleansing with holy water (Nirang), earth, &c.; next, by prayers (of which sixteen, at least, are to be recited every day) and the recitation of the divine word; but other self-castigations, fasting, celibacy, &c., are considered hateful to the Divinity. The ethical code may be summed up in the three words—purity of thought, of word, and of deed: a religion 'that is for all, and not for any particular nation,' as the Zoroastrians say. It need hardly be added, that superstitions of all kinds have, in the course of the tribulations of ages, and the intimacy with neighboring countries, greatly defiled the original purity of this creed, and that its forms now vary much among the different communities of the present time.

Something like a very serious schism, however, has lately broken out in the Parsee communities, and the modern terms of Conservative and Liberal, or rather bigot and infidel, are almost as freely used with them as in Europe. The sum and substance of these innovations, stoutly advocated by one side, and as stoutly resisted by the other, is the desire to abolish the purification by the Nirang—a filthy substance in itself—to reduce the large number of obligatory prayers, to stop early betrothal and marriage, to suppress the extravagance in funerals and weddings, to educate women, and to admit them into society. Two counter alliances or societies, the 'Guides of the Worshipers of God' and 'the True Guides' respectively, are trying to carry out at this moment, by means of meetings, speeches, tracts, &c., the objects of their different parties.

The literature of the Parsees will be found noticed under PERSIAN LANGUAGE AND LITERATURE, and ZEND-AVESTA. Besides the latter, which is written in ancient Zend, and its Gujarati translation and commentaries, there are to be mentioned, as works specially treating of religious matters, the *Zardusht-Nameh*, or Legendary History of Zerdusht; the *Sadder*, or Summary of Parsee Doctrines; the *Dabistan*, or School of Manners; the *Desatir*, or Sacred Writings, &c. All these have been translated into English and other European languages.

On the influence Parsism has had upon Judaism and its later doctrines and ceremonial, and, through it, upon Christianity and Mohammedanism—which besides drew from it directly—we cannot dwell here at any length. So much, however, may be stated, that the most cursory reading of the sacred Parsee books will show, in a variety of points, their direct influence upon the three Semitic creeds. Of works treating on the subject of this article, we mention principally, Hyde, *Vet. Rel. Pers. Hist.* (Oxon. 1760, 4to); Ouseley, *Travels in the East* (Lond. 1819); Anquetil du Perron, *Exposition des Usages des Parsees*; Rhode, *Die heil. Sage der alten Babylonier*, *Meder u. Perser*, &c. (Frank-a-M., 1820, 8vo); Dosabhoj Framjee, *The Parsees*, &c. (Lond. 1858); Dadabhai Naoroji, *The Manners and Customs of the Parsees*; and *The Parsee Religion*

(Liverpool, 1861, 8vo); and lastly, Haug's *Essays on the Parsee Religion* (Bombay, 1862), and Spiegel's *Erân* (Berl. 1863).

PA'RSLEY (*Petroselinum*), a genus of plants of the natural order *Umbellifera*. The species are annual or biennial, branching, smooth, herbaceous plants, with variously pinnated leaves.—COMMON P. (*P. sativum*), which has tripinnate shining leaves, one of our best known culinary plants, is a native of the south of Europe, growing chiefly on rocks and old walls, and naturalized in some parts of England. The cultivation of P. is extremely simple, and an annual sowing is generally made, although when cut over and prevented from flowering, the plant lives for several years. A variety with curled leaflets is generally preferred to the common kind with plain leaflets, as finer and more beautiful, being often used as a garnish; it is also safer, as the poisonous Fool's P. (*q. v.*) is sometimes gathered by mistake instead of the other.—HAMBURG P. is a variety with a large white carrot-like root, cultivated for the sake of its root, and much in the same way as the carrot or parsnip. To produce large roots and of delicate flavor, a very rich soil is required. The foliage of P. is not merely of use for flavoring soups, &c., but is nutritious at the same time that it is stimulating, a quality which it seems to derive from an essential oil present in every part of the plant. P. contains also a peculiar gelatinous substance called *Apiine*. The bruised leaves of P. are sometimes employed as a stimulating poultice. The seeds are a deadly poison to many birds, and when powdered, they are sometimes used for killing lice.

PA'RSNIP (*Pastinaca*), a genus of plants of the natural order *Umbellifera*, having compound umbels with neither general nor partial involucre; yellow flowers with roundish, involute, sharp-pointed petals; calyx almost without teeth; fruit dorsally compressed and flat, with a broad border, the ridges very fine. The species are annual, biennial, or perennial herbaceous plants, with carrot-like, often fleshy roots, and pinnate leaves.—THE COMMON P. (*P. sativa*) is a native of England, although not of Scotland, and is abundant in some districts, particularly in chalky and gravelly soils. It is also found in many parts of Europe, and of the north of Asia. It is a biennial, with angular furrowed stem, 2–3 feet high, pinnate leaves with ovate leaflets, rather shining, cut and serrated, and a three-lobed terminal leaflet. The root of the wild plant is white, aromatic, mucilaginous, sweet, but with some acridness; and injurious effects have followed from its use. Cultivation has greatly modified the qualities both of the root and foliage, rendering them much more bland. The P. has long been cultivated for the sake of its root, which in cultivation has greatly increased in size, and become more fleshy. The flavor is disliked by some, as well as the too great sweetness, but highly relished by others; and the root of the P. is more nutritious than that of the carrot. The produce is also, on many soils, of larger quantity; and although the P. delights in a very open rich soil, it will succeed in clayey soils far too stiff for the carrot. It is rather remarkable that it has not been extensively cultivated as a field-crop, and for the feeding of cattle, except in the Channel Islands and in limited districts of continental Europe; more particularly as cattle are very fond of it, and not only the flesh of cattle fed on it is of excellent quality, but the butter of dairy-cows fed on parsnips in winter is far superior to that produced by almost any other kind of winter-feeding. The mode of cultivation of the P. scarcely differs from that of the carrot. There are several varieties in cultivation.

A very large variety cultivated in the Channel Islands on deep sandy soils, has roots sometimes three or four feet long; but this is fully twice the ordinary length, and there is a smaller turnip-rooted variety sometimes cultivated in gardens where the soil is very shallow. The P. is used chiefly in winter, whether for the table or for feeding cattle. It is improved rather than injured by frost; but is apt to become *rusty*, if allowed to remain too long in the ground; and exhibits acrid qualities after it has begun to grow again in spring. The root of the P. is much used in the north of Ireland for making a fermented liquor, with yeast and hops; and both in England and Ireland, for making *P. wine*, which has some resemblance to Malmsay wine.—Another species, the CUR-LEAVED P. or SEKAKUL (*P. Sekakul*), having pinnatifid cut leaflets, a native of India, Syria, and Egypt, is cultivated in the Levant, and is very similar in its uses to the common parsnip.

PARSON, in English Ecclesiastical Law, means the incumbent of a benefice in a parish. He is called parson (Lat. *persona*) because he represents the church for several purposes. He requires to be a member of the Established Church of England, and to be duly admitted to holy orders, presented, instituted, and inducted; and requires to be 23 years of age. When he is inducted, and not before, he is said to be in full and complete possession of the incumbency. The theory is, that the freehold of the parish church is vested in him, and as the legal owner, he has various rights of control over the chancel. He is also the owner of the churchyard, and as such is entitled to the grass. As owner of the body of the church, he has a right to control of the church bells, and is en-

titled to prevent the churchwardens from ringing them against his will. The distinction between a parson and vicar is, that the parson has generally the whole right to the ecclesiastical dues in the parish, whereas, the vicar has an appropriator over him, who is the real owner of the dues and tithes, and the vicar has only an inferior portion. The duty of the parson is to perform divine service in the parish church under the control of the bishop, to administer the sacraments to parishioners, to read the burial-service on request of the parishioners, to marry them in the parish church when they tender themselves. He is bound to reside in the parish, and is subject to penalties and forfeiture, if he without cause absent himself from the parish. He is subject to the Clergy Discipline Act, in case of misconduct.

PARSONSTOWN (anciently called BIRR), a considerable inland town on the river Brosna, in King's County, Ireland, 69 miles west-south-west from Dublin, with which city it is connected by a branch-line issuing from the great Southern and Western Railway at Ballybrophy. Pop. in 1881, 4955; of whom about 4000 were Roman Catholics, 700 Protestant Episcopalians, and the rest Protestants of other denominations. BIRR had its origin at an early period in a monastery founded by St. Brendan, and was the scene of many important events, both in the Irish and in the post-Invasion periods. The castle, which was anciently the seat of the O'Carrolls, was granted by Henry II. to Philip de Worcester; but it frequently changed masters, and even alternated between English and Irish hands. By James I., it was granted to Lawrence Parsons, ancestor of the present proprietor, the Earl of Rosse; but through the entire period of the civil wars, its possession was constantly disputed, until after 1690, when the Parsons family was finally established in possession. About this time, BIRR returned two members to parliament, but the privilege was temporary. The castle has been rebuilt. P. is one of the handsomest and best built inland towns in Ireland, with several fine churches and chapels, a nunnery, a statue of the Duke of Cumberland, a bronze statue (erected in 1876) of the third Earl of Rosse, a town-hall, a library, literary institute, a model and other schools. But the great attractions of P. are the castle, the observatory, and the laboratory of the late Earl of Rosse (q. v.), still maintained in active use by the present earl. P. is an important corn-market, a considerable center of inland commerce; but with the exception of a distillery and brewery, it is almost entirely without manufactures. It is a military station, and the seat of a union work-house.

PARS'WANATHA, the twenty-third of the deified saints of the Jainas, in the present era. He and *Mahaatra*, the twenty-fourth, are held in highest esteem, especially in Hindustan. In a suburb of Benares, called Belupura, there is a temple honored as the birthplace of PARS'WANATHA. See JAINAS.

PART, in music. When a piece of music consists of several series of sounds performed simultaneously, each series is called a part.

PARTA'NNA, a town of Sicily (prov. Trapani), 36 miles S.W. of Palermo. Pop. 13,000.

PARTERRE, in gardens laid out in the old French style, the open part in front of the house, in which flower-beds and closely-cut lawn were intermingled according to a regular plan.

PARTHENOGENESIS (from the Gr. *parthenos*, a virgin, and *genesis*, the act of production) is a term invented by Professor Owen to indicate propagation by self-splitting or self-dividing, by budding from without or within, and by any mode save by the act of impregnation; the parthenogenetic individuals being sexless or virgin females. See the article GENERATIONS, ALTERATION OF. For many remarkable facts in relation to parthenogenesis in insects, the reader is referred to Professor Owen's eighteenth lecture, *On the Anatomy and Physiology of Invertebrate Animals*; and to Siebold, *On Parthenogenesis*, translated by Dallas.

PARTHENON, the temple of Minerva at Athens; one of the most celebrated of the Greek temples, and usually regarded as the most perfect specimen of Greek architecture. Many of the sculptures have been brought to England, and are now in the British Museum. See GRECIAN ARCHITECTURE.

PARTHENOPEAN REPUBLIC (from *Parthenope*, the oldest name of the city of Naples) was the name given to the state into which the kingdom of Naples was transformed by the French Republicans, 23d January 1799, and which only lasted till the following June, when the invading army was forced to retreat.

PARTHIA, anciently a country of Western Asia, lying at the south-east end of the Caspian Sea, from which it was separated by a narrow strip, known as Hyrcania, now forms the northern portion of the province of Khorassan, and is an almost wholly mountainous region. Its rivers are merely mountain torrents, which are supplied by the melting snow on the Elburz range during winter and spring, but are mostly dry in summer and autumn.

The original inhabitants are believed to have been of Scythian

race, as shown by their language as well as by their manners, and to belong to the great Indo-Germanic family. If this be the case, as is very probable, the term Parthian, from its analogy to the Scythian word *parthe*, banished, seems to indicate that they were a tribe who had been driven to P. out of Scythia (i. e., Central Asia). The Parthians, during the time of the Roman Republic, were distinguished by primitive simplicity of life and extreme bravery, though at the same time much given to bacchanalian and voluptuous pleasures. They neglected agriculture and commerce, devoting their whole time to predatory expeditions and warfare. They fought on horseback, and after a peculiar fashion. Being armed solely with bows and arrows, they were rendered defenceless after the first discharge; and, to gain time for adjusting a second arrow to the bow, turned their horses, and retired, as if in full flight, but an enemy incautiously pursuing, was immediately assailed by a second flight of arrows; a second pretended flight followed, and the conflict was thus carried on till the Parthians gained the victory, or exhausted their quivers. They generally discharged their arrows backwards, holding the bow behind the shoulder; a mode of attack more dangerous to a pursuing enemy than to one in order of battle. The Parthians first appear in history as subject to the great Persian Empire. After the death of Alexander the Great, P. formed part of the Syrian kingdom, but revolted under Antiochus II., and constituted itself into an independent kingdom under the *Arsacidae* (see ARSACES), 250 B.C., a race of kings who exercised the most completely despotic authority ever known, treating their subjects as if the vilest of slaves; yet so accustomed did the Parthians become to this odious rule, that some of the later monarchs, who had received a Roman education, and after their accession treated their subjects with ordinary justice and humanity, were completely despised.

The capital of the Parthian monarchy was Hecatompylos ('the city of the hundred gates'), now Dangan. The Parthian dominion rapidly extended to the Euphrates on the west and the Indus on the east, and became a most powerful and flourishing empire; Seleucia, Ctesiphon—the capital of the Persian emperors of the Sassanidae—and other celebrated cities date their rise from this period, and soon eclipsed, in size and splendor, the ancient Hecatompylos. In spite of repeated attacks on the part of the Romans, the Parthians maintained their independence (see CRASSUS, SURENA); and though Trajan, in 115–116 A.D., seized certain portions of the country, the Romans were soon compelled to abandon them. In 214 A.D., during the reign of Artabanus IV., the last of the Arsacidae, a revolt, headed by Ardshir, son of Babegan, broke out in Persia, and the Parthian monarch, beaten in three engagements, lost his throne and life, while the victor substituted the Persian dynasty of the SASSANIDÆ (q. v.) for that of the Arsacidae. Some scions of the Parthian royal family continued for several centuries to rule over the mountainous district of Armenia, under the protection of the Romans, and made frequent descents upon Assyria and Babylonia; but their history is obscure and of little importance.

PARTIAL LOSS, in the law of Marine Insurance, is a loss which is not total; and therefore the insurer is not entitled to abandon or give up the remains of the ship or cargo, and claim the entire insurance money; but he is bound to keep his ship or goods, and claim only in proportion to his actual loss or damage.

PARTICIPLE (Lat. *participium*, part-taking), the name of a class of words which have the meaning of a verb with the form of an adjective. The name is said to have been given from their partaking of the nature both of a verb and of an adjective. Some grammarians make the participle a distinct part of speech, but it is more commonly classed as a part of the conjugation of the verb. There are in English two participles, one in *ing*, usually called the present, but properly the imperfect, because it expresses continued unfinished action, e. g., *loving, writing*; and the other expressing past action, and ending either in *ed* (t) or in *en*, e. g., *loved, written*. In Ang.-Sax. and Old Eng., the imperfect participle ended in *and*, e. g., *haband* (having), corresponding to the modern Ger. *habend*, Gr. *echont* (os), Lat. *habent* (is). In the sentence, 'He is *writing* a letter,' *writing* is the imperfect participle; in 'the *writing* of the letter occupies him,' or 'writing is a difficult art,' it is a substantive, and had a different origin. In the latter case, *ing* corresponds to the Ang.-Sax. termination *-ung*, used in forming substantives from a large class of verbs; thus, Ang.-Sax. *halgung* (hallowing) is equivalent in meaning and in etymology to Lat. *consecratio*; similarly, modern Ger. *Vernichtung*, annihilation, from *vernichten*, to annihilate. Such a phrase as, 'while the letter is *writing*,' seems to be a shortened form of the now antiquated, 'is a *writing*,' which was originally, 'is in *writing*.' Although this mode of expression is liable in some cases to ambiguity, it is terser and more idiomatic than the circumlocution of, 'is being written,' which is often substituted for it. The verbal substantive in *-ing* is often exactly equivalent to the infinitive; thus, 'standing long in one position is painful' = 'to stand,' &c. It has this advantage, that while it can be construed as a noun

(e.g., with a possessive case), it can retain at the same time the usual adjuncts of a verb; as, 'What are we to infer from the the king's dismissing his minister?' The use of this form contributes not a little to the peculiar brevity and strength of the English language.

PARTICK, a town of Scotland, in the county of Lanark, prettily situated, chiefly on a rising ground on the Kelvin, immediately above its junction with the Clyde, and about three miles west-north-west of the Cross of Glasgow, of which city it now forms a suburb. Nine-tenths of the workmen of P. are engaged in ship-building, and there are numerous ship-building yards, flour-mills, cotton factories, and bleach-fields. A large proportion of the inhabitants are engaged in business in Glasgow, and for their accommodation extensive ranges of handsome villas have been built here. Pop. (1851) 8181; (1861) 8188; (1871) 17,707; (1881) 27,410.

PARTINICO, **SALA DI**, a post-town of Sicily, in the province of Palermo, and 19 miles south-west of the city of that name, at the foot of a grand precipice of red limestone. The plain in the vicinity is of surpassing fertility; corn, wine, oil, fruit, and sumach are produced in rich abundance; and linen and woollen goods are manufactured. Pop. (1872) 20,154. Scattered vestiges of ancient habitations are still to be seen on the summit of the height above the town, and are said to be the ruins of the ancient *Parthenium* mentioned in the *Itinerary* of Antoninus, and there only.

PARTISAN is a name for a halberd or pike, or for a marshal's baton. The name is also given to the leader of a detached body of light troops, who make war by harassing the enemy, rather than coming to direct fighting, by cutting off stragglers, interrupting his supplies, and confusing him by rapid strategy. The action of such a corps is known as *Partisan warfare*.

PARTITION, a thin interior wall dividing one apartment from another. It is usually of brick-work, 4½ or 9 inches thick, or of timber with standards about 4½ inches thick covered with lath and plaster. Wooden partitions are used when there is no sufficient support for brick. When these have to carry joists or any other weight, they ought to be constructed in the form of a truss (q. v.).

PARTITION, or **PARTITURA**, in Music. See **SCORE**.

PARTITION LINES, in Heraldry, lines dividing the shield in directions corresponding to the ordinaries. According to the direction of the partition lines, a shield is said to be party or parted per fess, per pale, per bend, per chevron, per saltire; a

Partition Lines in Heraldry.

shield divided by lines in the direction of a cross, is said to be quartered; and a shield parted at once per cross and per saltire, is said to Gironné (q. v.) of eight. The partition lines are not always plain; they may be engrailed, invected, embattled, wavy, nebuly, indented, dancetté or raguly—forms which will be found explained under separate articles.

PARTNERSHIP, in the law of England, is the union of two or more individuals acting under a contract, whereby they mutually contribute their property or labor for the purpose of making profits jointly. When a partnership is confined to a particular transaction or speculation, it is usually called a joint-adventure, and the parties are joint-adventurers. The usual criterion by which a partnership is ascertained to exist, as distinguished from other arrangements, is that there is a community of profit; it is not essential that both should suffer losses equally or proportionably, for one partner may stipulate that he shall not be liable to loss. This stipulation is binding between the partners, but of course is insufficient to prevent the partners from being all liable to third parties. So one partner may contribute all the capital or all the labor. A dormant partner is one whose name does not generally appear to the world as a partner, but who nevertheless is to all intents and purposes a partner, with equal rights and liabilities to the rest. In order to constitute that kind of community of profit which is the chief ingredient in a partnership, it is necessary that the partner share in the profits as a partner; for in many cases, clerks, servants, or agents receive a commission or remuneration proportioned to profits, and yet are not partners, for this is merely one mode of ascertaining the salary which they

are to receive. In all such cases, therefore, the distinction as to whether there is a partnership or not turns on the consideration whether the alleged partner receives a share of the profits, as such, or merely receives a salary proportioned to profits, without having a specific interest in the firm.

The contract of partnership may be entered into either by word of mouth or in writing. If no specified term be agreed upon, it is a partnership at will, and may be dissolved by either of the parties at pleasure. Sometimes, also, the Court of Chancery will interfere to dissolve the partnership before the time appointed; but this only happens when some unforeseen and urgent reason exists, as that one of the partners has become a lunatic, or has proved grossly dishonest, or the object of the partnership cannot be carried out. Mere differences of opinion on minor matters are no ground for seeking a dissolution. The partners may make any kind of arrangement between themselves that they think proper; but if these are unusual and special stipulations, there is no certainty of securing the same being adhered to, without a formal deed or indenture of partnership being executed. Thus, it is common to stipulate as to the capital each is to contribute, and as to the proportion of profits he is to receive, as to what is to be done in case of the death of a partner, &c. Unless a stipulation is made to the contrary, the rule is, that the death of one of the partners dissolves the partnership. So does his bankruptcy. It is also a rule that no new partner can be introduced without the consent of the rest. There was once a peculiarity in the law of England as to the form of remedy—the rule being, that partners cannot sue each other in a court of law in respect of partnership transactions, but the only remedy is by a bill in Chancery. As against third parties, whatever may be the secret arrangements between themselves, the rule is, that any partner can bind the firm in all matters which are within the scope of the partnership, each being by the nature of the contract made the agent of all the rest for business purposes. Thus, any one may accept a bill in the name of the firm, provided such be one of the modes of doing business.

It is, however, to be borne in mind, that the firm is only bound by one of the partners in those matters which are strictly within the proper business of the firm, which is an important qualification of the general power. Within the above limits, each partner can bind the rest of his copartners, however imprudent or foolish may be his act, for it is one of the implied conditions, that all have full confidence in each other. It follows from this principle, that the firm is liable for the dealings of each partner on its behalf within the scope of the partnership, and each is liable to the full extent for all the debts of the firm; in short, each is liable to his last shilling for the solvency of the firm. Hence, it is often of importance for a partner, on leaving the firm, to know how to terminate this liability. The rule is, that as regards all strangers, a notice in the *Gazette* is good notice; but as between the firm and those who have had dealings with it, the *Gazette* notice is of no use, unless it can be proved that the party had actual notice given to him—and hence a circular notice sent to customers announcing the fact of retirement, is the only course effectual.

The practice of individuals entering into large associations, now called joint-stock companies, which were originally only extended partnerships, has led to a separate code as to these being framed for the United Kingdom. See **JOINT-STOCK COMPANIES**. The practise of limiting the liability of partners or shareholders in joint-stock companies had of late years led to the belief, that a similar restriction might well be extended to ordinary partnerships, and accordingly a bill was introduced into parliament in 1864 to enable this to be done. But that view was not carried out except to a limited extent, though an attempt was made to simplify some of the rules as to partnership liability, which are somewhat perplexing. It had long been matter of complaint that every man who had a share of the profits of a trade was said to be liable also to bear his share of the loss; whereas by lending money at a fixed rate of interest he was a mere creditor, and could be exposed to no risk but the loss of his advance.

The House of Lords, however, in 1860, had held it to be a mistake to suppose that a person who advanced money on terms of sharing profits was necessarily a partner. To remove part of the difficulty, however, an act of 28 and 29 Vict. c. 86 was passed, which enacts that if advances are made by written contract to a person in trade on terms of sharing profits, that of itself will not make the lender a partner. Nor will the payment of a servant or agent by a share of profits, nor the receipt by a deceased partner's widow or child of part of the profits as annuity, make any of these a partner. But the benefit of this act was confined in most cases to written contracts, and thus the old law remains as to other cases. It is still the law that a person, not a partner, becomes liable as one, if he has either represented himself as a partner, or authorized another so to represent him; and the third person dealing with the firm must have known this representation to enable him to hold the dormant partner liable. In 1870, a bill was passed 'to facilitate compromises and arrangements between

creditors and shareholders of joint-stock and other companies in liquidation,' but these points do not call for notice here.

In Scotland, the law of partnership, though in its essential features the same with the law of England, differs in one or two particulars. The partnership is treated as a distinct person in law, the partners being only its sureties or cautioners; and the consequence of this is, that in actions by or against the firm, the individual partners need not be named, though in practice one or two of them generally are named. Each partner may also sue the firm as if it were a distinct person; and the firm may be made bankrupt without any of the partners being sequestrated. See *Paterson's Comp. of E. and S. Law*, p. 214.

PARTRIDGE (*Perdix*), a genus of gallinaceous birds, of the family *Tetraonidae*, having a short, strong bill, naked at the base; the upper mandible convex, bent down at the tip; the wings and tail short, the tarsi as well as the toes naked, the tarsi not spurred.—The COMMON P., or GRAY P. (*P. cinerea*), is the most plentiful of all the game-birds in Britain, and becomes increasingly plentiful as cultivation is extended, whilst the range of the moorfowl is restricted. It is not found in the Outer Hebrides. On the continent of Europe, it is abundant in almost all districts suitable to its habits, from Scandinavia to the Mediterranean, and is found also in the north of Africa, and in some parts of the west of Asia. It varies considerably in size; those found in rich lowlands being generally the largest, and about 12½ inches in entire length; whilst those which inhabit poorer and more upland districts are rather smaller. The female is rather smaller than the male. The upper parts of both are ash-gray, finely varied with brown and black; the male has a deep chestnut crescent-shaped spot on the breast, which is almost or altogether wanting in the female. A variety called the Mountain P. has the plumage brown. The P. is seldom found far from cultivated land. It feeds on grain and other seeds, insects and their larvæ and pupæ, and the pupæ of ants are generally the food sought at first for the young. The nest is usually on the ground, among brushwood and long grass, or in fields of clover or corn, and generally contains from twelve to twenty eggs. The young run as soon as they are hatched. Both parents show a very strong attachment to their young, and great courage in repelling assailants; they have also recourse, like many other birds, to stratagem, to draw off the most powerful and dangerous enemies, such as dogs, in another direction, fluttering close before them as if broken-winged, whilst the brood escape. Until the end of autumn, the parent birds and their broods keep together in a covey; late in the season, several coveys often unite into a pack, when it becomes much more difficult for the sportsman to approach them.

The flight of the P. is strong and rapid for a short distance, but it does not seem to be capable of a long-sustained flight. The eggs of partridges are often hatched, and the young birds reared, by the domestic hen, the chief requisite being a plentiful supply of ants when the birds are very young. Partridges thus reared become very tame, but they seldom breed in the aviary.—The RED-LEGGED P. (*P. rufus*, or *Caccabis rufus*), the genus or subgenus *Caccabis* being distinguished by a rudimentary blunt spur on the tarsi) is a native of the south of Europe and of the Channel Islands, and is now also plentiful in some parts of England, particularly Norfolk and Suffolk, into which it has been introduced. It is rather larger than the Common P., stronger on the wing, and less easily approached by the sportsman, whilst it is also less esteemed for the table. The upper parts are of a reddish-ash color; the throat and cheeks white, bounded by a collar of black, which expands in black spots on the breast; and the sides exhibit bars of black. The plumage is smooth.—Two other species, nearly allied to this, are found in some of the southern parts of Europe. India has a number of species. The habits of all the species much resemble those of the Common Partridge.—The name P. is sometimes extended so as to include the species of *Oryz* (see VIRGINIAN QUAIL), and in South America is sometimes given to the Tinamous.

PARTRIDGE BERRY. See GAULTHERIA.

PARTRIDGE PIGEON (*Geophaps*), an Australian genus of *Columbida*, approaching more than most of the pigeons, in character and habits, to the true gallinaceous birds and particularly to partridges. Their plumage is beautiful, and generally with a bronze tinge and lustre on the wings, which causes them to be sometimes called Bronze-wings. There are several species. They live mostly on the ground, and rise with a whirring noise, like the pheasant, when disturbed. They are highly esteemed for the table.—*Geotrygon montana*, a species of another genus of *Columbida*, bears the name of PARTRIDGE DOVE in the West Indies. It also seeks its food chiefly on the ground, although it affects well-wooded districts.

PARTRIDGES, in Artillery, were very large bombards formerly in use at sieges and in defensive works. They are mentioned in Froissart.

PARTRIDGE-WOOD, a very pretty hard-wood from the West Indies and Brazil; it is usually of a reddish color, in various shade from light to dark, the shades being mingled in thin streaks; but in some choice sorts they are curled upon one another so as to resemble the feathers of the partridge, whence its name. One variety occurs in which the colors are remarkably bright, and it is consequently called Pheasant-wood. In Brazil, this beautiful wood is so plentiful that it is employed in ship-building, and it is said to be used in our navy-yards under the name of Cabbage-wood, but this is doubtful; many woods are known as partridge, and several as cabbage-wood. Among the Brazilians, it is called 'Angelim,' and they describe four sorts—*Angelim de pedra* (the Stone Angelim), *A. vermelho* (Red Angelim), *A. amargoso* (Bitter Angelim), and *A. varzea* (Cultivated Angelim). Its chief use in this country is for cabinet-work, Tunbridge-ware, parasol-sticks, fans, and other small matters for which its beauty recommends it. It is said to be yielded by the leguminous tree (*Andira inermis*), which is found not only in the Brazils, but in other parts of South America and the West Indies.

PARTS OF SPEECH are the several kinds or classes into which the words of a language are divided. There is nothing in the outward form of words that would enable us to divide them into classes. The distinction lies in the offices that the several words perform in a sentence (q. v.). All words performing the same office in sentences belong to the same class. The essential parts of speech are the Noun, Adjective, Pronoun, Verb, Adverb, Preposition, Conjunction (see these several heads). The Articles (q. v.) are not distinct parts of speech, being essentially pronouns; and Interjections (q. v.) hardly belong to articulate speech. To name the class or part of speech to which each word of a sentence belongs, is called to *parse* it.

PARTURITION. See MIDWIFERY.

PARTY, in Heraldry. See PARTITION LINES.

PARTY-WALL is the wall dividing two houses or tenements, and which is, in a certain sense, one and indivisible, though the property of two or more parties. The question as to who is the owner of any particular part of the party-wall, is solved by ascertaining who is the owner of the soil on which it is built. In the absence of evidence to the contrary, it is presumed that half of the soil belongs to the owner on one side, and the other half to the owner of the other side; and unless the wall has stood twenty years and upwards, each owner can do what he likes with his own half, and can pare it away if he likes. But in general, mutual interest prevents each party from resorting to his strict legal rights. A practice exists for one who builds a house adjoining the wall of a neighbor, to pay for half the expense. In Scotland, a party building close to the wall of another's house, can compel the owner of the first house to give him half of the wall or gable, on paying half the expense; while in England there is no such compulsion.

In Scotland, where the practice exists of building houses in flats lying each upon the other, the law is not clearly settled, and requires to be cleared up as to what is the nature of the property or interest which each proprietor of a flat has in that part of the gable bounding his own flat. The better opinion is, that each is the entire owner of his half of the gable, the others having merely cross servitudes; and hence it follows, that if the flats on both sides of a gable belong to one owner, he can make a communication through the gable, provided he do not injure the chimney-flues of the lower flats, or the stability of the structure.

PARVATI (from the Sanscrit *parvata*, mountain, literally, mountain-born) is one of the names by which Durgā, the consort of Śiva, is usually called, she being the daughter of the mountain Himalaya.

PA'RVISE, a porch or open space in front of the door of a church.

PASCAGOU'LA, a river, and bay at its mouth, in Mississippi, U. S. The river, formed by the junction of the Leaf, the Chickahay, with numerous branches, drains the south-eastern portion of the state, and flows into Mississippi Sound through two mouths which form the bay. It is navigable 100 miles through a sandy region of pine-forests, supplying turpentine. The villages on the bay are summer resorts from Mobile and New Orleans; and on the shores at night are heard sounds like the Æolian harp, supposed to be caused by some kind of shell-fish.

PASCAL, BLAISE, one of the most distinguished philosophers and scholars of the 17th c., was born at Clermont, in Auvergne, France, June 19, 1623. His father, Etienne Pascal, was president of the Cour des Aides at Clermont. His mother, Antoinette Bezon, died while he was little beyond infancy. He had two sisters—the elder, Gilberte, Madame Perier, afterwards his biographer; the younger, Jacqueline, who became a nun of Port Royal, under the celebrated Mère Angelique, sister of Antoine Arnauld.

From childhood, Blaise gave evidence of extraordinary abilities; and when he reached his eighth year, his father resigned his office at Clermont, and came to Paris, in order personally to direct the boy's education. For the purpose of concentrating all the boy's efforts upon languages, his father kept out of his reach all books treating the subject of mathematics, for which he had early evinced a decided taste; and it is recorded that by his own unaided speculations, drawing the diagrams with charcoal upon the floor, he made some progress in geometry. One account represents him as having thus mastered the first thirty-two propositions of the first book of Euclid's *Elements*—a statement which carries its own refutation with it. Thenceforward, he was permitted freely to follow the bent of his genius. In his sixteenth year, he produced a treatise on Conic Sections, which extorted the almost incredulous admiration of Descartes. In his nineteenth year, he invented a calculating-machine; and turning his attention to the novel questions as to the nature of fluids, which Torricelli's theories had raised, he produced two essays, which, although not published till after his death, have established his reputation as an experimental physicist. His father having accepted an office at Rouen, P. was there brought much into intercourse with a distinguished preacher, Abbé Guillebert, a member of the Jansenists, but a man of great eloquence, a great master of ascetic theology, from whom and from other members of the same rigid sect, as well as from the writings of Arnauld, St. Cyran, and Nicole, P.'s mind received a deeply religious turn; and his health having suffered much from excessive study, he gave himself up in great measure to retirement and theological reading, and to the practice of asceticism. The death of his father, and his sister Jacqueline's withdrawal to Port Royal, confirmed these habits; and it is to this period that we owe his magnificent though unfinished *Pensées*, which have extorted the admiration even of his unbelieving, and therefore unsympathizing critics.

Having fully identified himself with the Jansenist party, he was induced (1655) to take up his residence at Port Royal, although not as a member of the body, where he resided till his death, entirely given up to prayer and practices of mortification, among which practices may be mentioned that of wearing an iron girdle, studded with sharp points, which he forced into his flesh whenever he felt himself assailed by sinful thoughts. In the controversy to which the condemnation of Arnauld by the Sorbonne (1655) gave rise, P. took a lively interest; and it was to this controversy that he contributed the memorable *Lettres Provinciales*, published under the pseudonym of Louis de Montalt. These famous Letters (eighteen in number, not reckoning the nineteenth, which is a fragment, and the twentieth, which is by Lemaître), are written, as if to a provincial friend, on the absorbing controversial topic of the day. The first three are devoted to the vindication of Arnauld, and the demonstration of the identity of his doctrine with that of St. Augustine. But it was to the later letters that the collection owed both its contemporary popularity and its abiding fame. In these P. addresses himself to the casuistry and to the directorial system of Arnauld's great antagonists, the Jesuits; and in a strain of humorous irony which has seldom been surpassed, he holds up to ridicule their imputed laxity of principle on the obligation of restitution, on simony, on probable opinions, on directing the intention, on equivocation and mental reservation, &c. In all this, he professes to produce the authorities of their own authors. Of the extraordinary ability displayed in these celebrated Letters, no question can be entertained; but the Jesuits and their friends loudly complain of their unfairness, and represent them as in great part the work of a special pleader. The quotations, with the exception of those from Escobar, were confessedly supplied by P.'s friends.

It is complained that many of the authors cited are not Jesuits at all; that many of the opinions ridiculed and reprobated as opinions of the Jesuit order, had been in reality formally repudiated and condemned in the Society; that many of the extracts are garbled and distorted; that it treats as though they had been designed for the pulpit and as manuals for teaching, works which in reality were but meant as private directions of the judgment of the confessor; and that, in almost all cases, statements, facts, and circumstances are withheld, which would modify, if not entirely remove, their objectionable tendency. See JESUITS. To all which the enemies of the Jesuits reply, by arguments intended thoroughly to vindicate Pascal. P. himself entertained no compunctious feeling for the production of these Letters, but even at the approach of death declared his full satisfaction with the work, such as it was. His later years were made very wretched by continued, or at least frequently recurring hypochondria, under the influence of which he suffered from very painful fantasies, which he was unable to control. His strength was completely worn out by these and other infirmities, and, prematurely old, he died at the early age of thirty-nine in Paris, in the year 1662. His *Pensées sur la Religion, et sur quelques autres Sujets*, being unfinished, were published with suppressions and modifications in 1669; but their full value was only learned from the complete

edition which was published at the instance of M. Cousin (Paris, 1844). Of all his works, the *Lettres Provinciales* have been the most frequently reprinted. They were translated into Latin in the lifetime of P. by Nicole, under the pseudonym of a German professor, 'Wilhelm Wendrock;' and an edition in four languages appeared at Cologne, in 1684.

PASCHAL. See PASSOVER.

PA'SCO, or CE'RO DE PASCO, an important mining city in Peru, in the department of Junin, stands at an elevation of about 14,000 feet above sea-level, 80 miles north-east of Lima, in a direct line, but upwards of 130 miles by the winding mountain road. It consists of a collection of huts spread over an area that has been hollowed out and perforated in all directions by mines. The number of the inhabitants varies according to the state of the mines; being sometimes considerably more than 12,000 and often much less. It possesses a journal of literature and mining. The Cerro, or 'mountain knot,' of Pasco rises, in Sacshuanata, 16,000 feet above the level of the sea. Coal is found.

PAS-DE-CALAIS (Fr. for Strait of Dover), a department in the north of France, bounded on the N. by the department of Nord and the Strait of Dover, and on the W. by the Strait of Dover and the English Channel. Area, 2540 square miles, of which 883,300 acres are cultivated, and 236,707 in meadows. Pop. (1880) 819,022. The surface is level, with the exception of a ridge of hills running from the south-east to the north-west, ending in Gris-nez Cape (q. v.), and forming the water-shed between the North Sea and the English Channel. The rivers, which are of no considerable length, are the Scarpe and Lys in the basin of the North Sea, and the Authie and Canche belonging to the basin of the English Channel. The rivers are navigable within the department, and are connected by canals. The coast-line is 80 miles in length, and the shores are in certain parts low and sandy; while for several miles on either side of Gris-nez, cliffs similar to those of Dover front the sea. The climate is mild, but exceedingly inconstant. The soil is very fertile—all the usual cereal and leguminous crops are produced in abundance—and the country is very productive both as regards agriculture and manufactures. Fishing is actively carried on, on the coast particularly in the neighborhood of Boulogne. Coal of an indifferent quality is raised, the excellent quarries of the department are worked, and considerable quantities of turf are cut.

The industrial establishments are numerous and important, as iron-foundries, glass-works, potteries, tanneries, and numerous bleach-works, and mills and factories of various kinds. Boulogne and Calais are the principal harbors. There are six arrondissements—Arras, Béthune, St. Omer, St. Pol, Boulogne, and Montreuil. The capital is Arras.

PASENG. See GOAT.

PA'SEWALK, a town of Prussia, in the government of Stettin, 25 miles west-north-west of the city of that name, on the Uker. It contains two churches, two hospitals, and several woollen-cloth and leather factories; and carries on an active general trade. Pop. (1880) 9469.

PASHA', or PACHA, a title used in the Ottoman empire, and applied to governors of provinces, or military and naval commanders of high rank. The name is said to be derived from two Persian words—*pa*, foot or support, and *shah*, ruler—and signifies 'the support of the ruler.' The title was limited in the early period of the Ottoman empire to the princes of the blood, but was subsequently extended to the grand-vizier, the members of the divan, the seraskier, capitan-pasha, the begler-begs, and other civil and military authorities. The distinctive badge of a pasha is a horse's tail, waving from the end of a staff, crowned with a gilt ball; in war, this badge is always carried before him when he goes abroad, and is at other times planted in front of his tent. The three grades of pashas are distinguished by the number of the horse-tails on their standards; those of the highest rank are pashas of three tails, and include, in general, the highest functionaries, civil and military. All pashas of this class have the title of vizier; and the grand-vizier is, *par excellence*, a pasha of three tails. The pashas of two tails are the governors of provinces, who generally are called by the simple title 'pasha.' The lowest rank of pasha is the pasha of one tail; the sanjaks, or lowest class of provincial governors, are of this rank.

The pasha of a province has authority over the military force, the revenue, and the administration of justice. His authority was formerly absolute, but recently a check was imposed on him by the appointment of local councils. The pasha is in his own person the military leader and administrator of justice for the province under his charge, and holds office during the pleasure of the sultan—a most precarious tenure, as the sultan can at any moment, in the exercise of his despotic power, exile, imprison, or put him to death; and this has frequently been done in cases where the pasha's power has excited the apprehension, or his wealth the aversion of his royal master.

PASKEVITCH, IVAN FEODOROVITCH, Count of Erivan, Prince of Warsaw, and a Russian field-marshal, was born at Poltava, May 19, 1782. He was descended from a Polish family, and was at first a page to the Czar Paul, but entered the army, and served in the campaign in 1805, which was ended by the defeat of Austerlitz; and then against the Turks. He took a prominent part in the campaign of 1812, and several times defeated the French under Eugène, Ney, and St. Cyr; he was also present at Leipzig and the conflicts under the walls of Paris. In 1825, he was appointed commander-in-chief against the Persians, whom he completely defeated, conquering Persian Armenia, taking Erivan, and ending the war by the peace of Turkmanshah (q. v.), a peace exceedingly favorable to Russia. In recompense for these services, he was created Count of Erivan, and received a grant of 1,000,000 rubles (£158,600). In 1828 and 1829, he made two campaigns against the Turks in Asia, signalized by the taking of Kars, Erzerum, and other important provinces, and terminated by the treaty of Adrianople in 1829.

In 1831, P., now a field-marshal, was appointed viceroy of Poland, put an end to the revolt within three months after his appointment, and reconstructed the administration on the basis of a complete incorporation with Russia. Such was the vigor and severity of his rule, that the eventful year 1848 passed over without any attempt at revolution. When Russian intervention in Hungary had been resolved upon, P., though now 67 years of age, marched into that country at the head of 200,000 men, and, after a junction with the Austrians, defeated the Hungarians in several battles, and by mere force of numbers crushed out the last spark of insurrection. The 50th anniversary of his military service was celebrated at Warsaw, in 1850, with the utmost rejoicings, and on this occasion the sovereigns of Austria and Prussia conferred on him the rank of field-marshal in their respective armies. In 1854, he unwillingly took the command of the Russian army on the Danube; but fortune, which had hitherto invariably smiled upon him, deserted him at Silistria; and after undergoing a succession of sanguinary repulses, and being himself grievously wounded, he withdrew his army, and resigning the command, retired to Warsaw, where he fell into a state of profound melancholy, and died January 29, 1856.

PA'SMA is the name given to a non-official healing-powder, which is regarded as very serviceable in burns, ulcers, excoriations, &c. It is composed of 30 parts of silica, 13 of magnesia, 6 of alumina, 2 of protoxide of iron, and 50 of starch from the oilgro root.

PA'SPALUM, a genus of grasses, with spikes either solitary or variously grouped, one-flowered spikelets, and awnless paleæ. The species are numerous, natives of warm climates.—*P. serotum* is cultivated as a cereal in India, where it is called Koda. See MILLET. It will grow in very barren soils, and delights in a dry louse soil. *P. exile* is cultivated in like manner in the west of Africa, where it is called Fundi (q. v.) or Fundungi.—Other species are valuable as fodder-grasses. *P. purpureum* is a very important fodder-grass in the coast districts of Peru, during the dry months of February and March. *P. stoloniferum*, also a Peruvian species, has been introduced into France; but is apt to be injured by frosts, and seldom ripens its seeds in the neighborhood of Paris.

PASQUE FLOWER (*Pulsatilla*), a genus of plants of the

Pasque Flower (*Anemone pulsatilla*).

natural order *Ranunculaceæ*, by many botanists still included in

Anemone, the chief distinguishing characteristic being the long feathery awns of the fruit. The species are perennial, silky, herbaceous plants, with doubly pinnatifid or doubly trifid leaves, and a simple one-flowered scape. They are narcotic, acrid, and poisonous. The Common P. (*Pulsatilla vulgaris* or *Anemone pulsatilla*) is a native of many parts of Europe, and of chalky pastures in several parts of England. It has widely bell-shaped bluish-purple flowers. Another species, P. or *A. pratensis*, a native of the continent of Europe, not of Britain, has smaller and more perfectly bell-shaped blackish-purple flowers.—These plants emit, when bruised, a pungent smell; and contain, as their principal constituent, a peculiar pungent essential oil, which, in combination with *Anemoniac Acid*, forms an acrid and very inflammable substance called *Anemonine*, or *Pulsatilla Camphor*, and is sometimes used in medicine. *Pulsatilla* is a favorite medicine of the homeopaths. *Easter Eggs* are colored purple in some places by the petals of the pasque flower.—More acrid than any of the species just named is *Pulsatilla patens*, which occasionally even blisters the skin.

PASQUINA'DE, an anonymous or pseudonymous publication of small size, sometimes printed, sometimes only posted up or circulated in manuscript, and having for its object the defamation of a character, or at least the turning of a person to ridicule. The name is derived from *Pasquino*, a tailor remarkable for his wit and sarcastic humor, who lived in Rome towards the close of the 15th c., and attracted many to his shop by his sharp and lively sayings. Some time after his death, a mutilated fragment of an ancient statue, considered to represent Menelaus supporting the dead body of Patroclus, was dug up opposite his shop, and placed at the end of the Braschi Palace, near the Piazza Navoni. It was named after the defunct tailor, and thus the practice originated of affixing to it placards containing satires and jests relative to the affairs of the day—the pope and the cardinals being favorite victims of the invisible satirists. It till recently continued to be the only outlet which the Roman had for his opinions and feelings. One or two may be quoted as specimens of the mordant style of the Pasquin statue. 'Great sums,' said the satirist one day, in an epigram addressed to Pope Paul III., 'were formerly given to poets for singing; how much will you give me, O Paul, to be silent?'—On the marriage of a young Roman called Cesare to a girl called Roma, the statue gave the following advice: 'Cave, Cæsar, ne tua Roma republica fiat.' Next day the rival statue of Marforio, in the Capitol, replied: 'Cæsar imperat;' to which Pasquin with exquisite malice retorted: 'Ergo coronabitur.'

PA'SSAGE, WEST, a seaport town upon the western shore of the estuary of the river Lee, in the county of Cork, Ireland, which has risen into importance chiefly as a watering-place, and as the shipping-port and marine suburb of the city of Cork, from which it is distant, by the Cork and Passage Railway, about 6 miles. As the river above P. is not navigable for ships above 400 or 500 tons burden, ships of higher tonnage discharge their cargoes at Passage. It is also a ship-building station. Pop. 2440, about four-fifths of whom are Catholics. The rest belong mainly to the Protestant Episcopal Church, other denominations being sparsely represented.—There is another small town of the same name, **EAST PASSAGE**, near the mouth of the Suir, in the county of Waterford; pop. (1881) 688.

PASSAGLIA, CARLO, a Roman Catholic theologian of great eminence, who has obtained much notoriety in connection with the recent movement for the unity of Italy, is a native of the duchy of Lucca, where he was born May 2, 1812. His origin is very humble, and he entered extremely young as a scholar of the Jesuit Society, of which he was enrolled a member in the year 1827. Having obtained much distinction in the schools of the order, and having, as is usual with its members, taught for some time in the lower schools, he completed his theological studies in the Roman College, and was appointed Professor of Canon Law, and eventually of Dogmatical Theology. His reputation for learning stood in the very first rank of Roman Catholic theology, and his lectures were exceedingly admired for their eloquence and erudition, but were considered in some respects too diffuse for the class of pupils who frequented his school. During the temporary withdrawal of the Jesuits from Rome in 1848—1851, P. with some of his brethren came to England, where he taught theology to the young brethren of his order, and on the re-establishment of the Jesuits in the Roman College, he resumed possession of his chair.

During the discussions which preceded the definition of the doctrine of the Immaculate Conception of the blessed Virgin Mary (q. v.), P. published an elaborate treatise on the doctrine and history of that question, which was published at the cost of the Roman government. Soon afterwards, however, the dissatisfaction which was expressed at the unsuitable character and method of his lectures by the authorities of the order led to his resignation of the professorship of theology. Still, however, he continued a member of the Society; and the pope, who felt a warm

friendship for him, established in the Roman university a special chair of Philosophy for him, which he did not long retain. In 1858 or 1859, he left the Society of the Jesuits, and entered warmly into the discussions as to the temporal power of the pope, in connection with which he undertook a voluntary mission to Turin, which, however, led to no results. Having fallen under suspicion in Rome, and his house having been invaded by a domiciliary visit of the police, he withdrew from that city to Turin, where he established a journal entitled *Il Mediatore*, which appeared till 1866. He was appointed by the king professor of moral philosophy, and subsequently of theology in the university of Turin. In 1863 he became a member of the Turin parliament, but his success fell far short of his reputation. He is said to have sought reconciliation with the Church, but to have failed to make the required retraction.

P.'s principal works are the treatise on the Immaculate Conception already referred to (4 vols. 4to); a treatise (Latin) on the Primacy of St. Peter (8vo, 1850); a Scholastic treatise entitled *Commentarius Theologicus de Partitione Divinae Voluntatis* (8vo, Rome, 1851), an apology for the cause of Italian unity, entitled *Pro Causa Italica; ad Episcopos Catholicos* (Florence, 1861), in which he recommends the church to make peace with the nation; several essays on religious and political subjects, and recently a learned and very detailed Reply to Renan's *Vie de Jesus* (Italian).

PASSA'IC, a river of New Jersey, U. S., rises in Morris County, and after a circuitous south-easterly course of 90 miles, empties into Newark Bay. It is navigable for sloops for a short distance; and its falls of 72 feet at Patterson, furnish water-power to numerous factories, and are an attraction to tourists.

PASSAMAQU'DDY BAY opens out of the Bay of Fundy, between Maine and New Brunswick, North America. It is 12 miles long by 6 wide, and shut in by a cluster of islands so as to form an excellent harbor. It receives the St. Croix, Didgequash, and other rivers, and forms the harbor of the flourishing town of Eastport. The bay abounds in fish, and has tides of 25 feet.

PA'SSANT, a heraldic term used to express the attitude of an animal in a walking position, with his head straight before him

(fig. 1); fig. 2 represents the attitude, *Passant gardant*; fig. 3, *Passant regardant*.

PASSA'ROWITZ, or POSHAREWATZ (Servian *Pozarevaz*), a town in the principality of Servia, 5 miles south of the Danube. Its streets are wide and unpaved, its houses detached, and surrounded with palisades. Pop. (1874) 7829. The town is chiefly noteworthy for the treaty which was signed here by Prince Eugene and the grand vizier, July 21, 1718. By this treaty, which put an end to the war undertaken by the Turks against Venice in 1714 for the conquest of the Morea, a truce of 25 years was established, and the Banat of Temesvar, the western portion of Walachia and Servia, the town and territory of Belgrade, and a part of Bosnia, were secured to the House of Austria.

PASSAU, an ancient, picturesque, frontier town of Bavaria, at the confluence of the Inn and the Ilz with the Danube, 90 miles east-north-east of Munich. It consists of P. Proper (triangular in shape, and occupying an eminence on the tongue of land between the right bank of the Danube and the left bank of the Inn), and the suburbs, Innstadt, on the right bank of the Inn; Anger and Fort Oberhaus, between the Danube and the Ilz; and Ilzstadt, on the left bank of the Ilz. At the point of junction, the Inn is both wider and has had a longer course than the Danube, the former being 834 feet; while the latter is only 696 feet wide. The railway bridge and another iron bridge on eight piers of granite, connect Innstadt with P., and the Danube is crossed by a fine bridge resting on seven piers, also of granite. Fort Oberhaus, on the left bank of the Danube, stands on steep, wooded cliffs, at an elevation of upwards of 400 feet, and is connected with the castle of Niederhaus by old walls; both are now used as prisons for criminals from the upper classes and military offenders. The appearance of P., situated at the confluence of two great rivers, and rising like an amphitheater on the most beautiful spot of the Danube, is strikingly effective and picturesque. Among the chief buildings are the cathedral, the bishop's palace, the post-office, where the treaty of P. was signed in 1552; the Jesuits' College, a large building, now used as a school; and the Church of St. Michael's. In the Cathedral Square (Domplatz) is a bronze statue of King Maximilian Joseph, erected in 1828. P. contains also numerous picture-galleries, collections of antiquities,

and benevolent and charitable institutions. The women of P. are famous for their beauty. Pop. (1875) 14,752; (1880) 15,365.

The natural advantages of this site, in a military point of view, were appreciated at an early period by the Romans, who erected a strong camp here, garrisoned it with Batavian troops, and from this circumstance named it *Batava Castra*. P. was long the seat of an independent bishopric founded in the 7th c., but secularized in 1803. By the treaty of P., signed here in 1552 by the emperor Charles V. on the one side, and the Protestant princes of Germany on the other, public recognition of the Lutheran faith among the institutions of the empire was granted. The cathedral of P. and great part of the town were consumed by fire in 1662.

PASSECAILLE and PASSEPIED, two old French dances, the music of the former being in $\frac{2}{4}$, the latter in $\frac{3}{4}$ time. Compositions under these names, suggestive of the dances in question, though not meant for dancing, occur among the 'Suites,' or collections of short pieces for the harpsichord or clavichord by Sebastian Bach and Handel.

PA'SSENGER PIGEON (*Ectopistes migratorius*), a species of pigeon, native of North America, and particularly interesting from the marvelous numbers of which its flocks are often composed. The genus to which it belongs has, like the turtle doves, a bill more slender than the ordinary pigeons, notched, and with a tumid fleshy covering above at the base; the head is small in proportion to the body, the legs are short and strong, the feet naked, the tail either rounded or wedge-shaped, the wings long and pointed.

The P. P., generally known in North America as the Wild Pigeon, has a long wedge-shaped tail; the whole length being from 15 to 17 inches, of which the tail occupies nearly one half. It is a beautiful bird, of very graceful form and finely-colored plumage. The plumage of the female is duller than that of the

Passenger Pigeon (*Ectopistes migratorius*).

male.—The P. P. is found in almost all parts of North America, from the Gulf of Mexico to the Arctic regions. It is not, properly speaking, a bird of passage; its migrations being apparently altogether consequent on the failure of the supplies of food in one locality, and the necessity of seeking it in another, and not connected with the breeding season or the season of the year. Its power of flight is very great, and it is supposed to be able to sustain a long flight at the rate of sixty miles an hour. Passenger pigeons have been killed in the neighborhood of New York, with their crops full of rice, which they must have collected in the fields of Carolina or Georgia not many hours before. It is not, therefore, very wonderful that wanderers of this species should occasionally appear in Britain and in other regions far from their native abode. The nest of the P. P. in the American forests generally consists of a few dry twigs placed in a fork of the branches of a tree, and containing two eggs, sometimes only one egg. They breed two or three times in a season. In the backwoods, vast numbers of pigeons building in one breeding-place, many nests, sometimes 100 or more, are often to be seen in one tree. These great breeding-places extend over a vast tract of forest, sometimes not less than forty miles in length; but in the more cultivated parts of the United States the P. P. builds singly and not in communities.

The numbers of birds forming the communities of the western forests surpass calculation. Flocks of them are to be seen flying at a great height in dense columns, eight or ten miles long; and there is reason to suppose, from the rapidity of their flight, and the number of hours taken by a column in passing a particular spot, that in some of their great migrations the column, a mile broad, is more than 150 miles long. Their roosting-places, as

well as their breeding-places, are of prodigious magnitude. The graphic descriptions of Wilson and Audubon are too long to be quoted; but there is perhaps nothing of the kind so wonderful in relation to any species of bird. The noise of wings and of cooing voices is as loud as thunder, and is heard at the distance of miles. It drowns the report of guns. The multitudes which settle on trees, break down great branches by their weight, so that it is dangerous to pass beneath. They crowd together, alighting one upon another, till they form solid masses like hogheads, and great numbers are killed when the branches break. The inhabitants of the neighboring country assemble, shoot them, knock them down with poles, stifle them by means of pots of burning sulphur, cut down trees in order to bring them in great numbers to the ground, eat them, salt them, and bring their hogs to fatten on them. Wolves, foxes, lynxes, cougars, bears, raccoons, opossums, polecats, eagles, hawks, and vultures all congregate to share the spoil. The flesh of the P. P. is of a dark color, but tolerably pleasant. That of young birds is much esteemed. The nestlings are in general extremely fat, and are sometimes melted down for the sake of their fat alone. The food of the P. P. consists chiefly of beech-mast and acorns, but it readily eats almost any kind of nut, berry, or seed.

PASSENGERS BY LAND AND SEA. The law affecting passengers by land, in a carriage or public conveyance, may be stated as follows: The owners of the railway or other carriage do not contract to carry the passenger with perfect safety; they do not warrant that he will not be injured; but they merely contract to carry him without any negligence on their part. Hence, in case of accident, though it is not strictly correct in point of law to assume that the accident arose from some negligence of the carrier, unless there is evidence to support it, this presumption is in point of fact always made, and it lies on the carrier to show that it was from no fault or negligence on his part that the accident happened. As questions of negligence must almost always be decided by a jury, and their prepossessions are against admitting the idea that accidents arise from any cause except negligence of the carrier—which is a wholesome doctrine—it seldom ever happens that a railway or public company attempt to dispute their responsibility on that ground. The rule is that a railway company is responsible for the negligence of any of their servants; and hence, in case of accidents, all passengers injured, and in case of death, the parent, husband, wife, or children of the deceased passenger, invariably make a claim of compensation, except when the accident was caused by the passenger's own personal negligence. For while a carrier is bound to use due care to carry the passenger with safety, it is equally true that the passenger is at the same time bound to take ordinary care of himself, and not act in a rash or foolish way, so as to lead to an accident. Before railways and canals were in use, it was sometimes doubted whether it was not the duty of carriers by coach to carry all persons who presented themselves and offered to pay their fare; but this notion is exploded, and even railway companies are not bound to carry everybody who comes, but merely to give reasonable accommodation to the ordinary number, otherwise their liability would be enormous on particular occasions where crowds assemble. Their interest is usually a sufficient inducement on such occasions to provide the accommodation required. A passenger has a right to carry along with him Luggage (q. v.).

In the case of passengers by sea, a peculiar code has been constructed, owing to the peculiarity of their situation. The fundamental rule of the common law is the same as on land carriage—that the carrier by sea does not engage to carry with absolute safety, but merely to omit nothing in his power, and to use due care. The legislature, however, has passed statutes to regulate the duties of carriers by sea, so as to secure due care; and their minute and detailed regulations apply to every sea-going vessel, whether British or foreign, carrying more than fifty passengers. Payment of the passage money must be made before commencing the voyage, and the owners are not bound to forward steerage passengers by the very ship contracted for, if an equally eligible ship be offered, provided, however, that families are not to be separated. If the ship is disabled on the voyage, the owners are bound to repair the ship in six weeks, or send on the passengers. If the passengers exceed 300, a medical practitioner must be on board, and the provisions must be according to a certain scale of diet. The Emigration Commissioners require to inspect emigrant ships, and to give a certificate as to fitness. As to passenger steamers in this country, a certificate is required from the Board of Trade, specifying the voyage and number of passengers allowed to be carried, and their survey, once every year.

PA'SSERINE BIRDS. See INSESSORES.

PASSING-BELL, a bell tolled during the death agony of a dying person, at the moment of the soul's 'passing' from earth to its eternal abode. Its use in Catholic countries is to invite the hearers to join in the prayers which are ordered for the dying in

their 'hour of agony,' and which the priest with his attendants recite in the death chamber. See BELL.

PASSING-NOTES, in Music. In passing from one chord to another, an intervening note, not belonging to either chord, may be used to assist the progression. Such a note is called a passing-note or note of transition, as the notes D and F in the upper part of the subjoined example:

PA'SSION CROSS, a cross of the form on which our Saviour suffered, with a long stem and a short traverse near the top. It is of occasional occurrence as a heraldic charge, though less frequent than many other varieties of cross. A passion cross, when elevated on three steps or degrees (which have been said by heralds to represent the virtues of Faith, Hope, and Charity), is called a Cross Calvary.

PASSIONFLOWER (*Passiflora*), a genus of plants almost exclusively natives of the warm parts of America, and belonging to the natural order *Passifloraceae*; an order of exogenous plants, of which more than 200 species are known, mostly climbers, having tendrils which spring from the axils of the leaves, herbaceous or half shrubby, natives of tropical and subtropical countries, but rare in Asia and Africa. The leaves of the *Passifloraceae* are alternate, simple, and variously lobed. The flowers are generally

Passionflower (*Passiflora corulea*).

hermaphrodite, with a colored calyx, generally of five segments; the segments of the corolla equal in number to those of the calyx or absent, and several rows of filamentous processes springing from within the cup which is formed by the consolidated calyx and corolla; the stamens, generally five, and generally united by their filaments, inserted at the base of the tube of the calyx; the ovary free, generally elevated on a long stalk, one-celled; three thick styles with dilated stigmas; ovules numerous. The fruit is either fleshy or capsular. In the Passionflowers it is fleshy. This genus has received its name from fanciful persons among the first Spanish settlers in America, imagining that they saw in its flowers a representation of our Lord's passion; the filamentous processes being taken to represent the crown of thorns, the nail-shaped styles the nails of the cross, and the five anthers the marks of the wounds. The species are mostly half shrubby evergreen climbers, of rapid growth; and most of them have lobed leaves, with from two to seven lobes. The flowers of many are large and beautiful, on which account they are often cultivated in hothouses. Some of the species are also cultivated in tropical countries for their fruit, particularly those of which the fruit is known by the name Granadilla (q. v.).

The fruit of *P. edulis* is also somewhat acid and of a pleasant flavor, and is flavored with it are delicious. Its fruit is about two inches long, and an inch and a half in diameter, of a livid purple color, with orange pulp.—The fruit of some species of *P.*, however, is not only uneatable, but fetid; and the roots, leaves, and flowers of some, as well as of other *Passifloraceae*, have medicinal properties, narcotic, emmenagogue, antelmintic, febrifugal, &c. *P. rubra* is called Dutchman's Laudanum in Jamaica, because a tincture of the flowers is used as a substitute for laudanum.

num. The most hardy species of P. is the BLUE P. (*P. caerulea*), which grows well enough in some parts of France, and even in the south of England. Where the climate is suitable, passion-flowers form an admirable covering for arbors and trellises.

PASSIONISTS, a religious congregation of priests of the Roman Catholic Church, the object of whose institute, indicated by their name, is to preach 'Jesus Christ and him crucified.' The founder, Paul Francis, surnamed Paul of the Cross, was born in 1694 at Ovada, in the diocese of Acqui in the kingdom of Sardinia. Having commenced his career as a hermit he formed the design of enlisting others in the missionary life; and being ordained priest in 1737, he associated himself with ten others, and obtained for his plan the approbation of successive popes, together with the convent on the Celian Hill, at Rome, which still forms the mother-house of the congregation. The special object of the institute was to instil into men's minds by preaching, by example, and by devotional practices, a sense of the mercy and love of God as manifested in the passion of Christ. Hence the cross appears everywhere as their emblem, in their churches, in their halls, and in the courts and public places of their monasteries.

A large crucifix, moreover, forms part of their very striking costume. They go barefooted, and practise many other personal austerities, rising at midnight to recite the canonical hours in the church; and their ministerial work consist chiefly in holding what are called 'missions,' wherever they are invited by the local clergy, in which sermons on the passion of Christ, on sin, and on repentance, together with the hearing of confessions, hold the principal places. Paul of the Cross died in 1775. For a time his congregation remained in obscurity; but it has risen into notice within the last half century, new houses having been founded in England, Ireland, Belgium, America, and Australia.

PASSION PLAY. See MYSTERIES.

PASSION-WEEK, the name commonly given in England to the week immediately preceding Easter, and otherwise called **HOLY WEEK** (q. v.). But by the proper rubrical usage, Passion Week is that which precedes Holy Week, commencing on **PASSION SUNDAY**, the fifth Sunday of Lent. In the Roman calendar, the whole of the last fortnight of Lent is known by the name of Passion-tide, and all the services of that time differ in many respects from those, not alone of the year, but even of the rest of Lent. The verse *Gloria Patri* is discontinued both in the mass and in the Breviary, and all pictures, crucifixes, statues, and other sacred representations are veiled during the whole of Passion-tide.

PASSIVE TITLE, in the Law of Scotland, is the liability of an heir, or one who represents and interferes with the estate of a deceased person, to pay all the debts of the deceased. It was considered that so great an opportunity of fraud in secreting the goods of a deceased person existed, that the heir was presumed to be liable for all the debts of the deceased, unless he took good care to give up an inventory, and so show what property there was. The barbarous doctrine of holding an heir universally liable has latterly been much restricted; but the explanation is entirely technical.

PASSOVER (*Pesach, Pascha*), the first and greatest of the three annual feasts (*Regalim*) instituted by Moses, at which it was incumbent upon every male Israelite to make a pilgrimage to the house of the Lord. It was celebrated on the anniversary of the Exodus from Egypt—i. e., on the 14th day of Nisan, otherwise called Abib, the period of the first full moon in the spring—and lasted eight days. In commemoration of the incidents connected with the great event of the liberation of the people, it was ordained that unleavened bread only should be eaten during this festive period, whence it also bore the name *Chag hamazzoth* (Feast of Unleavened Bread); and, further, that a lamb one year old, and free from all blemish, roasted whole, together with bitter herbs, should form the meal in every house on the eve of the feast. Prayers and thanksgivings, all with a reference to the redemption from bondage, accompanied the repast, at which the members of the family or families who had joined in the purchase of the lamb had to appear in traveling garb. At a later period, a certain number of cups of red wine were superadded to this meal, to which, as its special ceremonies and the order of its benedictions were fixed, the name *Seder* (arrangement) was given. The name P. was more strictly limited to the first day, in which the paschal lamb was entirely consumed, the reserving of any part of it to the next day being expressly forbidden (Ex. xii. 10); and the name Feast of Unleavened Bread belonged rather to the remaining days, on which other animal food was eaten; but the names were often used indiscriminately.

The P. is generally regarded by Christian theologians as at once a sacrifice and a sacrament, and in the former character as an eminent type of the sacrifice of Christ. The death of Christ at the very time of the P. is regarded as corroborative of this view, which is indeed plainly adopted in certain passages of the New Testament, as John xix. 36, and 1 Cor. v. 7, in which last place our Saviour is designated 'Christ our Passover.' The P. is re-

garded as typical of Christ, in its connection with the deliverance of Israel from the bondage of Egypt, held to typify our salvation from the bondage of sin; in its being a sacrifice, and that of a lamb without blemish—the perfection of the paschal lamb, as of the other sacrificial victims, being supposed to signify the perfection of the great sacrifice; and in many other minor particulars, of which one is that referred to in John xix. 36, that no bone of the paschal lamb was to be broken.

The Paschal meal, as at present celebrated among the Jews, has more the character of a hallowed family-feast, with reference, however, to the great national event. The greater part of those—it may be added here—who live out of the Holy Land celebrate it on the two first evenings, as, owing to the uncertainty prevalent at one time with respect to the fixing of the new moon by the Sanhedrim at Jerusalem, it was ordained that the 'Exiles' should celebrate all their festivals—except the Day of Atonement—on two successive days, a law still in force among the orthodox. The regulations of the 'lamb for each house,' the traveling garb, &c., are abrogated, but many further symbolical tokens have been superadded; reminiscences, as it were, both of the liberation from Egypt, and the subsequent downfall of the sanctuary and empire. The order of prayers and songs to be recited on these evenings has also received many additions, and even medieval German songs have crept in, as supposed to contain a symbolical reference to the ultimate fate of Israel. See *HAGGADA* (*shel Pesach*), **FESTIVALS**, **EASTER**, **LORD'S SUPPER**.

PASSPORT, a warrant of protection and permission to travel, granted by the proper authority to persons moving from place to place. Every independent state has the right to exclude whom it pleases from its territory, and may require that all strangers entering it be furnished with properly authenticated documents, showing who they are, and for what purpose they are visiting the country. Passports are sometimes issued by the ministers and consuls of the country which the traveler intends to visit, which cannot, however, be done without the consent or connivance of the state of which the holder of the instrument is a subject; they properly proceed from the authorities of the state to which the traveler belongs, and ought to bear the *visa* or countersignature of the minister or consul of the country which he is about to visit. In some European states no one is allowed to go abroad without a passport from his government authorizing him to leave the country—a provision used as a means of detaining persons charged with crime; and passports are even required by the natives to enable them to go from place to place in their own country. The regulations of different states have varied much regarding the use of passports; and of late years there has been a great relaxation of the stringency of the regulations connected with them. Since the facilities of traveling have so greatly increased, it seems to have become the prevalent opinion that the passport system tends to obstruct the free intercourse that is desirable between citizens of different countries; while it is ineffectual to prevent the entrance of dangerous or suspicious characters, who can obtain passports on false pretences, or make their way in without them.

Within the United Kingdom, no passports are required; but for a British subject traveling in some parts of the continent they are still requisite. 'At one time the greater part of British subjects traveling abroad used to be furnished with passports from the ministers or consuls of the countries which they purposed to visit; the lord provost of Edinburgh was also in the way of issuing passports to Scotchmen. Of late years the passport most used by British subjects is that of the British Secretary of State for Foreign Affairs, which is now granted to any British subject for a fee of two shillings, and is good for life.' If the applicant be not personally known to the Secretary of State, he must either be recommended to him by some person who is known to him, or produce an application in his favor by some banking firm established in London or elsewhere in the United Kingdom, or a certificate of identity signed by a mayor, magistrate, justice of the peace, minister of religion, physician, surgeon, solicitor, or notary, resident in the United Kingdom. In certain cases, the production of a certificate of birth may be required. If the applicant be a naturalized British subject, his certificate of naturalization must be forwarded to the Foreign Office. If it be dated subsequently to 24th August 1850, and previously to 1st August, 1858, his passport will be good for one year only; if subsequently to 1st August 1858, for six months only. The passport of a British subject naturalized by act of parliament is good for life. Where the passport system is in full force, it is required that the passport be countersigned by the minister or consul of the country which the holder means to visit, the visa being only of force for a year.

The French government allows British subjects to enter and leave France, and travel in it without passports; but they are said to be sometimes asked for when France is entered from the south and east. In Belgium, Holland, Germany, Switzerland, Austria, Italy, Denmark, Norway, and Sweden, passports are no longer required. For Greece and Portugal they are necessary, and the

visa is insisted on in Russia, Turkey, and Egypt. A British subject traveling in countries where passports are not *de rigueur*, will sometimes find it an advantage to have one as an evidence of his identity and nationality. Till lately, throughout the greater part of Europe, a traveler was liable to be called on to produce his passport, not only at every frontier town, but at every garrison town through which he passed. In several of the countries where passports are not required of travelers, they are of a decided advantage, if not a necessity, to those who propose to settle there for some time—for example in Germany, especially since the anti-socialist legislation.

In time of war, passports or safe-conducts are granted by the supreme authority on the spot—i. e., the officer in command—to insure safety to the holders when passing from spot to spot, or while occupied in the performance of some act specified in and permitted by the passport. Passports may be granted for goods as well as individuals; and, in time of war, the passport of a ship is the formal voucher of its neutral character. It purports to be a requisition on the part of the government of a state to allow the vessel to pass freely with her company, passengers, goods, and merchandise, without hindrance, seizure, or molestation, as being owned by citizens or subjects of such state.

PASSY, a town of France, in the department of Seine, a suburb of Paris, and included within the fortifications of that city. See PARIS.

PASTA, GIUDITTA (JUDITH), one of the most distinguished opera singers of modern times, was born near Milan in Italy in 1798, and received her musical education partly at Como, under the chapel-master of the cathedral there, and partly in the conservatoire at Milan. After 1811 she appeared at various theaters of the second rank in Northern Italy, and obtained a respectable success, but did not give any particular indication of possessing more than average ability. Her first great triumph was achieved at Verona in 1822. The year following she was engaged at the Paris Italian Opera, where her singing excited great admiration. From this moment she labored incessantly to reach the ideal perfection she had set before her mind. From 1825 to 1830 was the period of her most splendid triumphs, which were won principally in London and Paris. Vienna, where she accepted an engagement in 1832, witnessed the last. Some time afterwards she withdrew from the stage, and purchased a villa on the banks of Lake Como, where, and at Milan, she resided till she died in 1865. P. in her best days had a magnificent voice, which easily passed from clear shrill soprano notes to the gravest contralto tones. In addition she had a fine dramatic energy and stateliness of manner, that suited lofty and imposing characters. Her principal rôles were *Medea*, *Desdemona*, *Semiramide*, *La Sonnambula* (the opera of this name was written for her by Bellini), and *Giulia* in *Romeo e Giulia*.

PASTE, a term applied to various compositions in which there is just sufficient moisture to soften without liquefying the mass.

Common or adhesive paste is made by mixing wheaten flour with cold water in the proportion of about two pounds to a gallon. The water is added by degrees, and well stirred in, so as to prevent lumpiness. About an ounce of powdered alum is sometimes added to increase its adhesiveness, and for shoemakers and bookbinders about an ounce and a half of finely-powdered rosin is substituted for the alum, which thickens it much and renders it much more tenacious. When the ingredients are thoroughly mixed, they are boiled, great care being taken to stir them thoroughly whilst boiling to prevent burning. This paste is used for a great variety of purposes, more especially by paper-hangers, bill-stickers, bookbinders, paste-board makers, &c. An adhesive paste, called *Chinese Paste*, is made by reducing to perfect dryness bullock's blood. It is then powdered and mixed with one tenth of its weight of finely-powdered quicklime. When used, it is mixed with water sufficient to form a paste, which is a strong cement for pottery, wood, stone, &c.

Fruit Paste is made by taking the juice of any fruit and dissolving in it an ounce to a pint of gum-arabic, or gum-senegal, which many prefer; then evaporate by a gentle heat until the liquid is as thick as syrup, and add to every pound of it a pound of finely-powdered refined-sugar; continue the heat, and stir it until the sugar and juice are thoroughly incorporated, after which it is poured out on a marble slab slightly oiled. When cooled, it may be formed into lozenges for use. An imitation of this is made very generally by mixing three parts of citric acid, twenty-four parts of gum, and forty-eight parts of refined sugar, and dissolving the whole in water, and gently heating it to insure complete solution and mixture. It is then variously colored and flavored with any of the fruit essences. This paste is often sold under the name of jujubes, which were formerly lozenges of fruit paste prepared from the juice of the jujube fruit, *Ziziphus jujuba*.

Polishing Pastes vary according to the materials upon which they are to be employed. For brass, the best kind is a mixture of two parts of soft soap with four parts of rotten-stone in very fine powder. Another sort is eight parts of fine rotten-stone

powder, two parts of oxalic acid powdered, three parts olive oil, and enough of turpentine to make them into a paste. For iron, a mixture of emery powder and lard is used; and for pewter a mixture of finely powdered bath-brick and soft soap. For wood, a paste called furniture paste is made by adding spirit of turpentine to beeswax sufficient to form it into a soft paste, which is rubbed on thinly with a brush and woollen rag, and afterwards polished with a dry woollen cloth and soft brush.

Shaving pastes are very numerous, but the base of all is soap. The best of all is the true Naples soap (see SOAP), but it is often mixed with other ingredients according to the fancy of the vendor. For other applications of the word Paste, see GEMS (IMITATION), and MACARONI.

PASTEL, chalk mixed with other materials and various colors, and formed into pencils or crayons (q. v.).

PASTEL. See WOAD.

PASTEUR, LOUIS, distinguished for his achievements in chemistry and microscopic biology, was born 27th December 1822, at Dôle in the department of Jura. On the completion of a course of scientific studies at Paris, he obtained chairs at Besançon, Dijon, Strassburg, Lille, and, in 1863, at Paris; and in 1867, he became professor of Chemistry in the Sorbonne. In molecular chemistry, P. has achieved important results; and in the province of fermentation, and the Germ Theory, his works are of special value. His studies on the diseased conditions of wine and of beer have rendered possible the prevention of these conditions. His investigations into the silk-worm's disease, *pebrine*, and its cure, have proved of signal service. His discovery of bacteria as the cause of anthrax (see SPLEENIC APOPLEXY) in cattle was quite an epoch in the science of disease. Similar results were obtained with regard to fowl cholera; and in his hands led to a very important method of preventing the various diseases caused by septic bacteria—viz., by inoculating the animals with a milder form of the disease by means of a weaker brood of bacteria, artificially cultured. In 1883 he studied cholera in Egypt. See GERM THEORY.

PASTILE, PASTIL, or PASTILLE, a diminutive of paste. This term was originally applied to lozenges as little portions of confectionery paste, but it has been of late chiefly confined to a mixture of odoriferous materials, as in the case of the *fumigating pastilles*, which are burned either as incense or as a means of diffusing an agreeable odor. They are composed of charcoal powder, with such aromatic gums as benzoin, labdanum, &c.; and powders of sweet-scented woods and barks, as sandal-wood, cinnamon, and especially cascarilla barks. Essential oils are also added, and the whole are worked into a paste with a little gum-mucilage, and formed into small sharp-pointed cones about an inch and a half high, and half an inch broad at the base. When perfectly dry, they are used by lighting at the point, and as they burn down an agreeable odor is given out with the smoke. Very tasteful vessels, called pastille burners, usually of porcelain, are made for using them. Another kind of pastille, usually in the form of a small pill covered with gold or silver leaf, is used for perfuming the breath; it is made of the same kind of ingredients, excepting the charcoal.

PASTO, a town of the United States of Colombia, on a high plateau between two ridges of the Andes, 148 miles north-east of Quito. Height above sea-level upwards of 8500 feet. It is in the direct route from the Popayan Pass to Quito. Pop. about 7000.

PASTOR, a genus of birds of the Starling family (*Sturnida*),

Rose-colored Pastor (*Pastor roseus*).

differing from starlings in the compressed and slightly-curved bill. In habits, as in characters, they are very nearly allied to starlings. The name P. is supposed to be derived from their being frequently seen with flocks of sheep. The only European species is the ROSE-COLORED P., or Rose-colored Ouzel (*P. roseus*), a rare visitant of Britain and of the northern parts of Europe, and more common in the north of Africa, Syria, and India than in any part of Europe.

PASTORAL LETTER, a letter addressed either at certain stated times, or on the occurrence of some notable occasion, by a 'pastor,' but especially by a bishop to the clergy under his jurisdiction, to the laity of his flock, or to both. Of the former class, in the Church of Rome, are the so-called Lenten Mandates, or Instructions, issued before the commencement of Lent, and making known the regulations enacted for the observance of the Lenten fast, the dispensations granted, and the devotions and other pious works prescribed. Such also are the letters issued by a bishop on many of the chief festivals of the year. It is usual for bishops, besides their stated letters, to address to their clergy or people instructions suited to any particular emergency which may arise, and sometimes to take occasion from the issuing of the stated pastoral letter to offer instruction on some topic of importance which may engage public attention at the time, on some prevalent abuse or scandal, or some apprehended danger to the faith or to morals. To this class belong many of the remains of the early fathers, especially in the Western Church. In some countries the government, as formerly in Austria, claimed a right to exercise a censorship over the pastoral letters to be issued by the bishops. This right, however, is regarded by churchmen as a usurpation, and although submitted to, is admitted only under protest. See PLACETUM REGIUM, FEBRONIANISM.

PASTORAL POETRY is that kind of poetry which professes to delineate the scenery, sentiment, and incidents of shepherd-life. It is highly probable that the first attempts to give a rhythmic expression to human feeling were to some extent of this character. Men were originally shepherds, and their festal songs and hymns would derive at least substance and imagery from their primitive occupations; but as a distinct branch of poetic art, pastoral poetry was not cultivated till a comparatively late period; for although critics are fond of pointing to the lives of the Hebrew patriarchs, and to the story of Ruth, as specimens of the antiquity of the pastoral in the East, yet, as these profess to be history, and not fiction, they can be instanced only to prove that the material for this kind of poetry existed from the earliest ages. In point of fact, it was only after innocence and simplicity had passed away, or were thought to have passed away, from real life, that men began, half from fancy, and half from memory, to paint the manners of the past as artless, and the lives of their ancestors as constantly happy. It was thus the *Brass Age* that made the *Golden*. The oldest specimens of the classic pastoral are the *Idylls of Theocritus* (q. v.), which appeared about 275 B. C.—long after Greece had produced her masterpieces in epic narrative, in the war ode, and almost all other kinds of the lyric, in tragedy, comedy, history, philosophy, and rhetoric. Theocritus was imitated by Bion and Moschus, whose pastorals approximate in form to the drama. Among the Latins, the refined and courtly Virgil, in the reign of Augustus, wrote his *Bucolica* or *Ecloques*, on the model of his Greek predecessors; but, however beautiful and melodious the verses of these urban writers are, we cannot suppose for a moment that the rude shepherds and shepherdesses of Italy or Sicily indulged in such refined sentiments, or spent their time so poetically as they are made to do. Virgil, we may rest assured, is as far from giving a genuine picture of pastoral life in his verse, as any modern poet who prates of Chloe and Phyllis.

During the middle ages, pastoral poetry in this artistic, and therefore conventional sense of the term, was almost unknown; but with the first glimpse of reviving classicism, the pastoral reappears. The earliest specimens are afforded by Boccaccio (q. v.), about the first modern Italian who studied Greek. It is to the countrymen of Boccaccio that we owe the creation of the pastoral drama, of which there is no trace in ancient literature. The *Favola di Orfeo* of Politian (q. v.), performed at the court of Mantua in 1483, is the first dramatic poem which pretends to represent the sentiments, incidents, and forms of pastoral life. Critics have forgotten this work when they make Tansillo the inventor of the *favola pastorale*, or *boscareccia*, on account of his *I due Pellegrini* (1539), or Agostino Beccari, whose pastoral comedy, *Il Sacrificio*, was played at Ferrara in 1554. However, it is true that the extraordinary popularity of Beccari's piece originated a crowd of *favole boscareccie*, the finest and most poetical of which is the *Aminta* of Tasso, represented at the court of Ferrara in 1572. A later, but hardly less famous production is the *Pastor Fido* of Guarini (q. v.), published at Venice in 1590; and in the 18th c., the poet Metastasio (q. v.) revived for a moment the interest in this graceful and picturesque, but unreal branch of literature. In Spain, during the first part of the 16th c., it abundantly flourished. The first who wrote pastoral dialogues was Juan del Encina (cir. 1500); he was followed by Garcilaso de la Vega, and others.

During the reign of the Emperor Charles V., one may say that Spanish imaginative literature was almost wholly of a bucolic character; but in Spain, as elsewhere, it took largely the form of prose-romance (see NOVELS) rather than of poetry, deriving its inspiration from the *Daphnis and Chloë* of Longus, the Byzantine romancist, not from the tuneful strains of the Mantuan swan.

England, however, can boast of Spenser's *Shepherd's Calendar*, which is at least full of charming poetry, and is appropriately dedicated to Sir Philip Sidney, whose pastoral romance of *Arcadia* outstrips in point of literary beauty all other fictions of that class. The Germans reckon Shakspeare's *As You Like It* in the list of pastoral dramas; but its right to be so classified is by no means clear, although we may admit that it betrays the influence of the pastoral poetry and romance that had just ceased to be the rage among the scholarly geniuses of Europe. A similar influence is visible in the writings of other Elizabethan dramatists, as, for example, in the *Faithful Shepherdess* of Fletcher. In France, pastoral poetry is perhaps older than in any of the western nations. The comedy of Adam de Lehalle, surnamed Le Bossu d'Arras (The Hunchback of Arras), entitled *Le Jeu de Robin et Marion* (and which exists in MS. in the *Bibliothèque Impériale*), belongs to the middle of the 13th century. During the civil wars in the latter half of the 16th c., the pastoral was turned to political uses. In the following century it continued for some time to be popular, or rather, let us say, fashionable. Even the great Richelieu alleviated the cares of office with the composition of *La Grande Pastorale*; but here, too, the poem soon gave way to the prose-romance, which was hardly less unreal, and more exciting.

Perhaps the best pastoral, ancient or modern, is the *Gentle Shepherd* of Allan Ramsay (q. v.), published in 1725. 'It is,' says Mr. Carruthers (Chambers's *Cyclopædia of English Literature*, vol. i., p. 601; p. 523 of 3d ed.), 'a genuine picture of Scottish life, but of life passed in simple rural employments, apart from the guilt and fever of large towns, and reflecting only the pure and unsophisticated emotions of our nature. The affected sensibilities and feigned distresses of the Corydons and Delias find no place in Ramsay's clear and manly page. He drew his shepherds from the life, placed them in scenes which he actually saw, and made them speak the language which he every day heard—the free idiomatic speech of his native vales.' His English contemporaries, Pope, Ambrose Philips, Gay, and others, who form the 'Augustan,' or Queen Anne school of poets, also addicted themselves to the composition of pastoral poetry; but though there is much fine description in the verses, they are, in general, purely conventional performances, in imitation of the classic poets, who, as we have said, did not themselves imitate nature. From this censure, however, must be excepted the six pastorals of Gay, entitled the *Shepherd's Week*, which are full of honest country humor, and contain charming pictures of English country life. Since the early part of the 18th c., however, pastoral poetry, strictly so called, has ceased to be cultivated in England and almost everywhere else. *In the pages of Wordsworth, who lived all his days among the Cumberland shepherds, we indeed find many exquisite glimpses of pastoral life, as it represented itself to the profound and tender imagination of that great poet of nature, but few direct delineations of pastoral manners. Germany imitated abundantly the French and Italian models during the greater part of the 18th century. The last and best of the German series is the *Erwin and Elmire* of Goethe's youth. The general impression appears to be that the age of pastoral poetry has passed away forever, and that Damon and Chloë will never reappear in verse.

PASTORAL STAFF, sometimes also, although not properly, called CROSIER (q. v.) (Lat. *baculus pastoralis*), one of the insignia of the episcopal office, sometimes also borne by an abbot. It is a tall staff of metal, or of wood ornamented with metal, having, at least in the Western Church, the head curved in the form of a shepherd's crook, as a symbol of the pastoral office. The head of the pastoral staff of an archbishop, instead of the crook, has a double cross, from which its name of *crosier* is derived. In the Greek Church the staff is much shorter, and the head is either a plain Greek cross of the form of the letter *Tau*, or it is a double-headed crook, which sometimes appears in the shape of the up-silon, *Ζ*. It is difficult to determine the time at which the pastoral staff first came into use. The first distinct allusion to it is in St. Augustine's commentary on the 124th psalm. Gregory of Tours, in his life of St. Martin, mentions the pastoral staff of St. Severinus, who was Bishop of Cologne in the end of the 4th century. From an early time, the pastoral staff was connected with the actual possession of the jurisdiction which it symbolizes. The giving of it was one of the ceremonies of investiture; its withdrawal was part of the form of deprivation; its voluntary abandonment accompanied the act of resignation; its being broken was the most solemn form of degradation. So also the veiling of the crook of an abbot's pastoral staff, during the episcopal visitation, signified the temporary subjection of his authority to that of the bishop.

Pastoral Staff.

An abbot being required to carry his pastoral staff with the crook turned inwards, showed that his authority was purely domestic. The pope alone does not use a pastoral staff. In the later mediæval period the material was often extremely costly, and, referring to the relaxation of the times, it was said 'that formerly the church had wooden pastoral staves and golden bishops, but that now the staves are of gold and the bishops of wood.' The workmanship was sometimes extremely beautiful. We annex as a specimen of the highest art the pastoral staff of William of Wykeham, now in New College, Oxford. This is a sample of the Norman pastoral staff. The Saxon was by no means so tall. The Irish pastoral staff is of a type quite peculiar, and some of the sculptured specimens preserved in the British Museum, at the Royal Irish Academy, and elsewhere, are very interesting. St. Fillan's Crosier, now in Edinburgh, resembles these.

PASTORAL THEOLOGY, that branch of theological science which regards the duties and obligations of pastors in relation to the care of souls. It comprises two parts; first, that which treats of the obligations of the pastors themselves, and which is therefore designed for the training and preparation of the candidates for the pastoral office. The other part of pastoral theology, which might perhaps better be called Popular Theology, comprises the objective teaching which is to be employed in the instruction and direction of the flock committed to the pastor's charge. This branch of theology has long formed a leading portion of the training of candidates in the Evangelical Churches of France and Germany. Numerous works on the subject represent the practice of the various sections of the Protestant church; and more recently Catholic manuals of P. T. have appeared.

PA'STRY, articles of food in which the chief part consists of a paste made of flour. This would of course apply to bread, but it has been limited by custom to such lighter articles as are made by the pastry-cook, and chiefly to those in which the paste is made to assume a light flaky character by the addition of butter, &c., and by the mode of working it up. The commonest kind is made of a dough of flour and water, into which butter or lard is worked by hand, in the proportion of six ounces to the pound. The finest kind is usually termed *puff paste*, and considerable skill is required to make it well, for it depends, next to the goodness of the materials, upon lightness of hand in kneading the ingredients together. These ingredients consist of fine wheaten flour and butter in the proportion of four ounces of butter to a pound of flour, with cold water just sufficient to make a good stiff elastic dough; this is rolled out with a *rolling-pin*, and double the previous quantity of butter is then spread over it. It is then rolled up and lightly kneaded, so as to work the butter in thoroughly. Coolness is very important in making pastry; a marble slab is therefore most desirable for making it upon. The thinner it is rolled out before the butter is then spread the better, because when it is put in the oven the laminæ which have been formed by folding or rolling up the butter with the dough, separate by the disengagement of the watery vapor, and the thinner and lighter the flakes are the better is the puff paste. Another kind is called *short paste*; in this the flour is made warm, and the butter or lard used is often melted, and a little sugar and an egg or two are added. This, when baked, has none of the flaky character of puff paste, but it is better adapted for meat and some other kinds of pies which require to be baked without a dish. Game-pies, with elaborately-decorated crusts, are made of this pastry.

PA'STURAGE, in English Law called Common of Pasture, is classed among rights of common or profits *à prendre*, and is the right of one who is not the owner of land to put his sheep or cattle on such land to feed there. In Scotland it is called a servitude of pasturage. In both countries the right can be established by prescription, in England of thirty years, and in Scotland of forty years. Where the parties entitled to pasturage dispute as to their respective proportions of cattle, the suit to redress the matter is called in Scotland an action of 'sowing and rowning.'

PA'STURES (Lat. *pasco*, to feed) are fields or tracts of land devoted to the feeding of oxen, sheep, and other herbivorous animals, which eat the grass and other herbage as it grows. Grass is grown sometimes in the rotation with grain and other crops, when it remains on the ground for one or more years, is frequently mown during the first summer, and grazed afterwards, but is again ploughed up to be succeeded usually by oats or wheat. For such purposes, rye-grass, red, white, yellow, and alsike clovers, are used either alone or mixed in varying proportions. On the uplands of Great Britain, wherever from any cause grain crops cannot profitably be grown, and throughout many of the richest plains and valleys, especially of England and Ireland, there are thousands of acres of land which have been under grass from time immemorial. Such permanent pastures are estimated to occupy fully 14,000,000 acres in England, nearly 8,000,000 in Scotland, and about 9,000,000 in Ireland. Sometimes they have been self-sown, occasionally they have been laid down with care,

seldom are they as highly cultivated and liberally managed as they should be. The best of them are used for feeding heavy bullocks; those of somewhat poorer description are often grazed by dairy stock; whilst the down or upland pastures are especially profitable for sheep.

It has now become a common practice, and is every year becoming more and more general, to give additional food of various kinds to animals fed on pastures. Even cattle grazing on the richest pastures are supplied with linseed cake, &c., to hasten the process of fattening, and to improve their quality; roots are given to sheep when fattening for the market, and hay to those which are to be kept as stock; whilst when oats or beans are cheap, many sheep-farmers find it advantageous to give them even to the hardy stock of exposed hill-pastures. All pastures are much improved by thorough drainage. The application of farmyard dung, soil, lime, and almost every sort of top-dressing is beneficial. Irrigation is sometimes profitable, and in some other countries is far more common and far more requisite than in Britain. Rich pastures on which oxen are fed are injured by sheep, which reject the coarsest grass, and pick out the finest; but a few horses turned into them during the autumn or winter help to consume the coarser tufts. The coarsest and rankest grass may once or twice a year be cut over by the scythe; and either made into rough hay, or if left on the ground, the cattle, when it has partially dried, will readily eat it up. A dressing of lime and salt scattered over the rougher parts of the fields in autumn will sweeten the herbage, and induce the stock to eat it down regularly. Moss, which is a great pest in many pastures, may be got rid of by penning sheep, well fed with swedes, cake, or corn, regularly over the field; or by harrowing the surface in several different directions during January or February, applying then a top-dressing of soil or dung, and in March or April sowing some clover or other seeds, which will be firmed down by the bush harrow, clod-crusher, or heavy roller. The droppings of the cattle ought to be broken up and scattered over the ground.

Rich pastures intended for the fattening of cattle ought not to be used during winter, but allowed to become luxuriant before the cattle are turned upon them in spring. Very lean animals, whether oxen or sheep, cannot with advantage be at once placed on very rich pasture, but must be gradually fitted for it. In some of the hill districts of Scotland, devoted to sheep-farming, increased productiveness has resulted from breaking up portions of the pasture, and after two or three crops have been taken, laying them down as pastures again. All good pastures produce a very mixed herbage, not consisting merely of one kind of grass, but of several or many, with clovers and other plants. Different species of Meadow-grass (*Poa*), Fescue (*Festuca*), Foxtail (*Alopecurus*), Oat-grass (*Avena*), Cock's-foot (*Dactylis glomerata*), Rye-grass (*Lolium*), Hair-grass (*Aira*), Vernal-grass (*Anthoxanthum*), and Timothy or Cat's-tail (*Phleum*), are among the most common grasses of British pastures. Yarrow (*Achillea millefolium*) is very abundant in some pastures, and is sometimes sown with grass, clover, &c., in land meant for permanent pasture. Different kinds of clover are adapted to different soils and situations. The presence of rushes is very indicative of the want of drainage. Thistles and docks are injurious, and are to be extirpated as much as possible. Some of the plants naturally abundant on high hill-pastures, as *Nardus stricta* and *Juncus bufonius*, are very unwholesome; and the substitution of others in their stead, is one of the benefits derived from the breaking up of such lands.

PATAGO'NIA, the most southern region of South America, extending from lat. 38° southwards to the Strait of Magellan, and occupying the extremity of the continent. The name P. is sometimes confined to the territory east of the Cordilleras; the district to the westward forming now a province of Chili. The possession of the country east of the Andes, long disputed, was in 1881 made over to the Argentine Republic. Length upwards of 1000 miles, greatest breadth about 480 miles; area about 350,000 square miles; population estimated by a recent traveler, Mr. Musters, at not more than 3000. The coast of the Atlantic has extensive bays and inlets, none of which, however, are of much importance or advantage, in a commercial point of view. Along the western coast, and stretching from 43° S. to the Strait of Magellan, are numerous islands, with precipitous shores, belonging apparently to the system of the Cordilleras. The principal islands are Chiloe, the Chonos Archipelago (q. v.), Wellington Island, the Archipelago of Madre de Dios, Queen Adelaide's Archipelago, and Desolation Island. These islands—which, together with several peninsulas, form a coast almost as rugged as that of Norway—are mountainous; but in none of them, except in Desolation Island, do the mountains rise to the snow-line.

Surface, Soil, &c.—The country of P. divides itself into two regions, very unequal in size and very different in character. These are Eastern and Western P., which are divided by the great mountain range of the Andes. Western P., comprising this range, the coast districts, and the islands, is rugged and moun-

tainous. Opposite the island of Chiloé are two active volcanoes, one of which, Minchinmavida, is 8000 feet high. The slope of the country from the Andes to the Pacific is so steep, and the strip of shore so narrow, that the largest river of this district has its origin only about 13 miles from its embouchure on the coast. In the island of Chiloé, in the north of Western P., the mean temperature of winter is about 40°, that of summer rather above 50°; while at Port Famine, in the extreme south of this region, and 800 miles nearer antarctic latitudes than Chiloé, the mean temperature is not much lower, being in winter about 33°, and in summer about 50°. This unusually small difference in the mean temperature of the extremes of Western P., which extends over about 14° of lat., is due to the great dampness of the atmosphere all along the coast. The prevailing winds of this region blow from the west; and, heavily surcharged with the moisture they have drawn from the immense wastes of the Pacific Ocean, they strike against the Andes, are thoroughly condensed by the cold high mountains, and fall in rains that are almost perpetual from Chiloé to the Strait of Magellan. South of 47° S. lat., hardly a day passes without a fall of rain, snow, or sleet. This continual dampness has produced forests of almost tropical luxuriance. A kind of deer wanders on the east side of the mountains; guanacos, pumas, and water-fowl abound in the region between the Andes and the Atlantic; and along the coast, seals, otters, sea-elephants, fish, and shell-fish are found.

Eastern P. comprises by far the larger portion of P., and extends eastward from the Andes to the Atlantic. Its surface has not yet been thoroughly explored, but the recent wanderings of Mr. Musters have at last furnished us with some authentic information. It mainly consists of high undulating plains or plateaux, frequently intersected by valleys and ravines, or rising into successive or isolated hills, which generally occupy the crest of the country. These plateaux are occasionally covered with coarse grass, but more frequently the surface is sterile, with a sparse vegetation of stunted bushes and round thistle clumps; and even these are sometimes wanting; absolutely nothing clothing the bare patches of clay or gravel; elsewhere, it is strewn with huge round boulders, and again rugged with confused heaps or ridges of bare, sharp-edged rocks, many of them of volcanic origin: this more particularly applying to the northern part of the country. Piercing blasts sweep almost incessantly from various points, but chiefly from the west; and snow, sleet, and rain seem to prevail during the greater part of the year. The descent from these plains or pampas to the valleys or more sheltered and fertile ground bordering the banks of the streams and rivers, is commonly termed 'barranca,' or bank, from the scarped slopes, varying in depth from fifty to two or three feet, and in angle from an easy to an almost perpendicular descent. The soil in many places is strongly impregnated with saltpetre, and salt-lakes and lagoons are numerous. North of the Rio Chico, and towards the sea-coast, there is a wild, weird, desolate region called by the Indians 'The Devil's Country'; it is said to be almost impassable. Several inhospitable wastes of this kind fringe the Atlantic, and have probably induced the belief that P. is a barren and waterless desert; but the interior, though not fertile, really abounds in lagoons, springs, and streams, and the banks of the Rio Negro and even the Santa Cruz are capable of cultivation.

Along the eastern base of the Andes, also, there is a great tract of territory which is astonishingly picturesque and fertile. Here great forests abound, to which the Indians retire for shelter from the freezing winds of winter. There are also deep valleys furrowed by mountain torrents; and numerous lakes, the haunts of wild-duck and other water-fowl. The largest of these lakes are Nahuel Huapi in the north, Coluguape in the middle, and Viedma in the south. Except pasture, Eastern P. has no productions. However fertile the soil in some places may be, it is nowhere cultivated. The Indians live upon the produce of the chase alone, and seem to desire no better sustenance. The principal rivers are the Rio Negro (q. v.); the Chupat, which flows through a good soil, producing excellent pasture and good firewood; the Rio Desire, probably rising in Lake Coluguape; and the Rio Chico, which flows out of Lake Viedma, through a valley sometimes opening out into wide grass-covered plains dotted with incense bushes, and sometimes rising in huge, bare ridge and burrow-like undulations. All these rivers rise in the Andes, and flow east or south-east. Herds of horses are reared, dogs abound, and, in the more favored regions, cattle are bred; pumas and foxes are met with, as well as condors, hawks, partridges, and water-fowl. But by far the most important animals are the guanaco or Huanaco (q. v.); the Rhea Darwinii, called by the Patagonians *mekyush*, and by the Spaniards *avestrus* or ostrich; and the gama, a kind of deer.

Inhabitants.—The Patagonians have been hitherto described only in the most general terms, and in many cases very inaccurately. Little was known of their appearance, habits, and employments. The work of M. Guinnard, *Trois Ans d'Esclavage chez les Patagons* (1864) was for a time believed to form a valuable addi-

tion to our knowledge of P. and its inhabitants; but the publication of Mr. Musters' record of his travels from the Straits of Magellan to the Rio Negro, under the title of *At Home with the Patagonians* (1871), has utterly destroyed the Frenchman's claim to be an authority. Mr. Musters is decidedly of the opinion that M. Guinnard was never in Patagonia at all, and that his 'experiences' were confined to the Indians north of the Rio Negro.

The Patagonians or Tehuelche Indians are divided into two great tribes, the northern and the southern. They speak the same language, but are distinguishable by difference of accent; and the southern men appear to be on an average taller and finer, and are more expert hunters. The northern range chiefly over the district between the Cordillera and the Atlantic, from the Rio Negro to the Chupat, and even the Santa Cruz River. The southern occupy the rest of P. as far south as the Strait of Magellan. The two divisions, however, are much intermixed, and frequently intermarry. The question is often asked: 'Are the Patagonians of gigantic stature?' Mr. Musters' statement is: 'The average height of the Tehuelche male members of our party with which I traveled was rather over than under 5 feet 10 inches.' Two others, measured carefully by Mr. Clarke (while resident at Santa Cruz), stood 6 feet 4 inches each. The muscular development of the arms and chest is extraordinary, and in general the Patagonians are well proportioned. They are splendid swimmers, can walk great distances without being tired, and can go for two and even three days without being tired.

As an illustration of their strength of arm, Musters mention that he has seen them 'ball' an ostrich over seventy yards distant. The expression of their face is ordinarily good-humored, except in the settlements: their eyes are bright and intelligent, their noses aquiline and well formed, their foreheads open and prominent. The complexion of the men, when cleansed from paint, is a reddish brown. Thick flowing masses of long hair cover their heads, and are combed out by their wives at least once a day. The scanty natural growth of beard, mustaches, and even eyebrows, is carefully eradicated. The young women are frequently good-looking, displaying healthy, ruddy cheeks when not disguised with paint. The dress of the men consists of a *chiripa* or under garment round the loins, made of a poncho, a piece of cloth, or other material; a long mantle of hide worn with the fur inside, and drooping in unbroken outline from their shoulders to the ground; and potro boots or buskins made from the skin of horse's hock, and occasionally from the leg of a large puma. The dress of the women is similar, except that the under garment is made of calico or stuff sacque, and extends from the shoulders to the ankle. Both sexes are fond of ornaments, wearing huge earrings of square shape, suspended from small rings passing through the lobe of the ear; also silver or blue bead necklaces. The reason assigned for the use of paint is that it forms a protection against sun and wind, and Musters states that he 'found from personal experience it proved a complete preservative from excoriation or a chapped skin.'

The arms of the Tehuelches consist of gun or revolver; sword or dagger; a long, heavy lance, used only by dismounted Indians, and altogether different from the light lance of Araucanian and Pampa horsemen; and the *bola perdida*, or single ball, so called because once thrown from the sling, it is not picked up again.

Their houses, called *toldos*, are formed of three rows of stakes driven into the ground. The middle row is higher than the others, and the three rows are tied together with strings of hide, and so kept in their place. This frail framework is covered with hides which reach the ground on all sides, and are fastened to it by small stakes of bone. At night-fall, guanaco hides are spread on the ground within the tents, and the men and women, laying aside their mantle, their only garment, and which sometimes serves as a blanket, go to sleep under the same roof and in the same apartment. Bathing in cold water every morning, throughout the whole year, is a custom to which men, women, and children conform; and although the morning bath may not free them from vermin—a national characteristic—yet it has the effect of preventing disease, and of enabling them the more easily to endure the severities of winter. Their only manufactures are mantles of guanaco hide, and saddles, bridles, stirrups, and lassos. The lassos and the articles of harness are chiefly plaited, and evince wonderful ingenuity and nicety of execution.

The religion of the Patagonians (according to Mr. Musters) is distinguished from that of the Pampas and Araucanians by an absence of any trace of sun-worship. They believe in a great and good spirit who created the Indians and animals, and who dispersed them from a place which they call 'God's Hill'; but Mr. Musters is inclined to think that this belief owes its origin to a confused apprehension of the story of creation as told by the Christian missionaries. Curiously enough, this great and good spirit takes no concern with the beings whom he has created. Idols are unknown, and during the whole of his wanderings, Mr. Musters saw no trace of any periodic religious festival. Whatever religious acts the natives performed were prompted by their

dread of malicious demons, the chief of whom, Gualichu, is always on the watch to cause mischief. To propitiate or drive away this spirit is the function of the wizard, doctor, or medicine-man, who (as in other countries) combines the medical and magical arts. The Gualichu lurks outside the *toldos*. He is invisible (except to the 'doctor,' who has the gift of second-sight), and he can enter into the bodies of people, and cause sickness and disease of every sort. Besides the Gualichu, there are, as has been said, many other evil spirits, who are supposed to inhabit subterranean dwellings, underneath certain woods and rivers, and peculiarly shaped rocks, all of whom are saluted on occasion with special incantations. The cry of the nightjar on the Cordillera betokens sickness or death, a certain toad-like lizard mysteriously lames horses, a fabulous two-headed guanaco is a sure forerunner of epidemic disease, &c. To counteract the influence of these, charms and talismans are liberally employed.

Their language is quite different from either Pampa or Araucanian. 'Though able to converse in Tehuelche,' says Mr. Musters, 'I could not at all understand the Pampas; and this is noted with reference to statements made in M. Guinnard's work, which, coupled with other internal evidences . . . compel me to doubt that the author was ever in the hands of the real Patagonians.' The same writer has a more favorable opinion of their character than is common. He found them 'kindly, good-tempered, impulsive children of nature, taking great likes or dislikes, becoming firm friends or equally confirmed enemies.' They are, however, 'steadily and rapidly decreasing,' through the combined effect of disease and bad liquor supplied to them by traders at the stations; and before long the race will be extirpated. The largest of these stations is Patagones (formerly El Carmen), at the mouth of the Río Negro, in the extreme north-east of the country, and bordering on the Argentine territory. It has a population of about 2000, composed of Spanish and other settlers, negroes, and convicts from Buenos Ayres. At the mouth of the Chupat there was from 1865 till 1870 an unprosperous Welsh colony; at the mouth of the Santa Cruz, further south, there is also a petty station; and at Punta Arenas (Sandy Point), on the Strait of Magellan, the Chilean government have established a colony and a penal settlement.

See *At Home with the Patagonians, a Year's Wanderings*, by George Chaworth Musters (Lond. 1871); more recently, *Across Patagonia*, by Lady Florence Dixie (1880).

PATAŁA (from *pat*, fall) is, in Hindu Mythology, the name of those inferior regions which have seven, or, according to some, eight divisions, each extending downwards ten thousand *yojanas*, or miles. The soil of these regions, as the *Vishn'u-Purān'a* relates, is severally white, black, purple, yellow, sandy, stony, and of gold; they are embellished with magnificent palaces, in which dwell numerous Dānavas, Daityas, Yakshas, and great snake-gods, decorated with brilliant jewels, and happy in the enjoyment of delicious viands and strong wines. There are in these regions beautiful groves, and streams and lakes, where the lotus blows, and the skies are resonant with the kokila's songs. They are, in short, so delightful, that the saint Nārada, after his return from them to heaven, declared among the celestials that P. was much more delightful than Indra's heaven. Professor Wilson, in his *Vishn'u-Purān'a*, says 'that there is no very copious description of Pātāla in any of the *Purān'as*; that the most circumstantial are those of the *Vāyu* and *Bhāgavata Purān'as*; and that the *Mahābhārata* and these two *Purān'as* assign different divisions to the Dānavas, Daityas, and Nāgas. . . . The regions of the Pātāla and their inhabitants are oftener the subjects of profane than of sacred fiction, in consequence of the frequent intercourse between mortal heroes and the serpent-maids. A considerable section of the *Vṛ'ihat-Kathā* consists of adventures and events in this subterranean world.' For inferior regions of a different description, see NARAKA.

PATANJALI is the name of two celebrated authors of ancient India, who are generally looked upon as the same personage, but apparently for no other reason than that they bear the same name. The one is the author of the system of philosophy called Yoga (q. v.), the other the great critic of Kātyāyana (q. v.) and Pāṇini (q. v.). Of the former, nothing is known beyond his work—for which see the article YOGA. The few historical facts relating to the latter, as at present ascertained, may be gathered from his great work, the *Mahābhāṣya*, or 'the great commentary.' The name of his mother was Gon'ikā; his birthplace was Gonarda, situated in the east of India, and he resided temporarily in Cashmere, where his work was especially patronized. From circumstantial evidence, Professor Goldstücker has, moreover, proved that he wrote between 140 and 120 B.C. (*Pāṇini's Place in Sanskrit Literature*, p. 235 ff.). The *Mahābhāṣya* of P. is not a full commentary on Pāṇini, but, with a few exceptions, only a commentary on the Vārttikas, or critical remarks of Kātyāyana on Pāṇini. 'Its method is analogous to that of other classical

commentaries: it establishes, usually by repetition, the correct reading of the text, in explaining every important or doubtful word, in showing the connection of the principal parts of the sentence, and in adding such observations as may be required for a better understanding of the author. But frequently Patanjali also attaches his own critical remarks to the emendations of Kātyāyana, often in support of the views of the latter, but not seldom, too, in order to refute his criticisms, and to defend Pāṇini; while, again, at other times, he completes the statement of one of them by his own additional rules.'

P. being the third of the grammatical triad of India (see PĀṆINI), and his work, therefore, having the advantage of profiting by the scholarship of his predecessors, he is looked upon as a paramount authority in all matters relating to classical Sanskrit grammar; and very justly so, for as to learning, ingenuity, and conscientiousness, there is no grammatical author of India who can be held superior to him. The *Mahābhāṣya* has been commented upon by Kaiyyat'a, in a work called the *Bhāṣya. Pradīpa*; and the latter has been annotated by Nagojibhatta, in a work called the *Bhāṣyapradīpodyota*. So much of these three latter works as relates to the first chapter of the first book of Pāṇini, together with the Vārttikas connected with them, has been edited at Mirzapore, 1856, by the late Dr. J. R. Ballantyne, who also gave a valuable literal translation of the first forty pages of the text.

PATA'PSCO, a river of Maryland, U.S., rises on the northern boundary of the state, and flows south-easterly 80 miles to the Chesapeake Bay, 14 miles south of Baltimore, to which city it is navigable. Its falls furnish water-power to numerous factories.

PATCHOULI. This very interesting material is the dried branches of *Pogostemon Patchouli* (natural order *Labiatae*), which was first introduced to this country as an article of merchandise in 1844. The plant is a native of Silhet, the Malay coast, Ceylon, Java, the neighborhood of Bombay, and probably also of China; but owing to the fondness of Asiatics for the perfume which it yields, it is difficult to say where it is native or cultivated. Every part of the plant is odoriferous, but the younger portions of the branches with the leaves are chosen; they are usually about a foot long. The odor is peculiar and difficult to define, but it has a slight resemblance to sandal-wood; it is very powerful, and to many persons is extremely disagreeable. The odor of patchouli was known in Europe before the material itself was introduced, in consequence of its use in Cashmere to scent the shawls with a view of keeping out moths, which are averse to it; hence the genuine Cashmere shawls were known by their scent, until the French found the secret, and imported the herb for use in the same way. Its name in India is *Pucha-pat*, and it is there used as an ingredient in fancy tobaccos, and as a perfume for the hair. It is also much prized for keeping insects from linen and woollen articles. The essence of patchouli is a peculiar heavy brown oil, with a disagreeably powerful odor; it is obtained by distillation, and requires extreme dilution for perfumery purposes.

PATE'LLA, or KNEE-CAP, is a Sesamoid Bone (q. v.), developed in the single tendon of the *rectus, vastus externus*, and *vastus internus* muscles—the greater extensor muscles of the leg. It is heart-shaped in form, the broad end being directed upwards, and the apex downwards. The anterior or external surface is convex, perforated by small apertures for the entrance of vessels, and marked by rough longitudinal striæ, while the posterior or internal surface is smooth, and divided into two facets by a vertical ridge, which corresponds and fits into the groove on the lower articulating surface of the femur or thigh-bone, while the two facets (of which the outer is the broader and deeper) correspond to the articular surface of the two condyles.

This bone is liable both to dislocation and fracture. Dislocation may occur either inwards or outwards; but it is most frequent in the outward direction. The displacement may be caused either by mechanical violence, or by too sudden contraction of the extensor muscles in whose conjoined tendon it lies; and is most liable to occur in knock-kneed, flabby persons. It may be readily detected by the impossibility of bending the knee, and by the bone being felt in its new position, and, except in one rare variety, the dislocation is capable of being reduced without any difficulty. Fracture of the patella may (like dislocation) be caused either by muscular action or by mechanical violence.

Fig. 1.—Posterior surface of right Patella.

- 1, outer facet; 2, inner facet;
- 3, surface to which the ligamentum patellæ is attached.

Fracture by muscular action is the more common of the two forms, and occurs thus: A person in danger of falling forwards, attempts to recover himself by throwing the body backwards, and the violent action of the extensors (chiefly the *rectus*) snaps the patella across, the upper fragment being drawn up the thigh, while the lower portion is retained *in situ* by that portion of the common tendon which is continued from the patella to the tubercle of the tibia, and which is called the ligamentum patellæ. The treatment consists in relaxing the opposing muscles by raising the trunk, and slightly elevating the limb, which should be kept in a straight position. In consequence of the great difficulty of bringing the broken surfaces into exact apposition, as may be readily understood from the accompanying figure, it is very difficult to obtain bony reunion of the parts, and the case generally results either in mere ligamentous union or in no true union at all.

Fig. 2.

PATELLA and PATELLIDÆ. See LIMPET.

PA'TEN (Lat. *patina*, a dish), the plate employed for the elements of bread in the Eucharistic service. Anciently it was of considerable size; and while the practice of the OFFERTORY (q. v.) continued, there was a special paten for the bread-offering. In the Roman Catholic Church, in which the unleavened wafer-bread is used, and the communion is distributed from a distinct vessel called PYX (q. v.), the paten is a small circular plate, always of the same material with the chalice. It is often richly chased or carved, and studded with precious stones. It is used only in the mass.

PATENT is an exclusive right granted by the crown (in letters patent or open, whence the name) to an individual to manufacture and sell a chattel or article of commerce of his own invention. The policy of the present law of patents has latterly been much canvassed, and it has been suggested that, instead of the present monopoly, with the drawback of litigation to which it uniformly gives rise, the use of all inventions should be dedicated to the public at once, and the inventor rewarded by a pension from the state, according to the merits and utility of the invention. The present law allows the inventor to have a monopoly of his invention for fourteen years, with a further privilege at the end of that time, provided he has not been sufficiently remunerated, to have the patent renewed for a further term of fourteen years. That some mode of rewarding the individual whose perseverance and ingenuity have enabled him to discover a new invention should be established, is universally admitted, but whether it should be at the expense of that part of the public who are purchasers, and therefore benefited by his discovery, or by the public at large in the shape of a pension, is a matter still undecided. The evils of the present law are that there is a great deal of uncertainty in the mode of ascertaining what is a new invention. Hence, when a patent has been granted, if it is of such a nature as to lead to competition, infringements are almost matters of course, and the only mode of discovering and checking the infringement is so tedious, costly, and ineffective, that inventors generally pass their lives in constant litigation, fighting in detail a succession of imitators who often have nothing to lose by defeat, and therefore entail all the greater burden on the legitimate manufacturer.

It has been said that not more than three patents per cent. are remunerative. A royal commission has latterly been engaged in inquiries as to the best mode of remunerating inventors, and improving the law in reference to infringements; but it is doubtful how far the subject is capable of being put on a better footing, so many difficulties being inherent in it. The crown seems always to have enjoyed the prerogative right to grant monopolies, and this had been so greatly perverted in the time of Elizabeth, that the popular clamor led to a statute in the following reign, having for its object to prevent the crown in future making any grants of that kind which should be prejudicial to the interests of trade. By that act an exception was expressly made in favor of new inventions. At first the judges construed grants of monopoly to inventors very strictly; but afterwards it was seen that they were for the benefit of trade, and were dealt with more liberally. An important modification of the law was introduced by a statute of Queen Anne, which required every inventor to describe in detail the nature of the invention in an instrument called a specification. Another statute of 5 and 6 Will. IV. c. 83, further altered the law by allowing parties who had a difficulty in separating what was new from what was old in their invention to enter an express

disclaimer of that part which was not new. But the most important alteration was made in 1852, by the statute of 15 and 16 Vict. c. 83, which reduced the fees, and otherwise improved the practice attending the obtaining of patents for the United Kingdom. Before stating shortly the substance of this act, it may be observed that there has always been a difficulty in defining what is an invention that is patentable—a difficulty which no act of parliament can get rid of, for it is inherent in the subject-matter. It has been held that a patent must be not merely a discovery of a new substance or article of food, but it must be a combination of processes producing some new result, or an old result by different means. It is of the essence of the patent that it be entirely new, that is, that it should not have been described in a published book, or well known in the business of the world, nor publicly used before. The specification must give a full disclosure of the secret, and describe it so that an intelligent person could from the description make the article itself.

There is a patent-office in London, in Edinburgh, and in Dublin, but the Scotch and Irish offices have long been used only as places for inspecting copies of patents, specifications, and documents. From 1852 till the new Act of 1883 came into force, the commissioners of patents were the Lord Chancellor, Master of the Rolls, Attorney and Solicitor General of England and Ireland, and the Lord Advocate and Solicitor-General of Scotland. The inventor first presented a petition for a grant of letters-patent, accompanied by a statement in writing of the specification, a copy of which was left at the patent-office. The application was referred, as a matter of course, to one of the law officers of the crown, who might call to his aid a scientific person to be paid by the applicant. A provisional patent might be applied for in the first instance, and the complete patent deferred for six months—the patent dating from the first application. After a patent was granted, and had been in existence for three years, a fee of £50 fell to be paid; and, at the end of the seven years, a fee of £100. The letters-patent extend to the whole of the United Kingdom. The practice with reference to patents, especially as to the drawing of the specification, was too minute to justify an inventor to attempt to take out a patent without professional aid; and a class of persons called patent agents (a business for which no qualifications were required by any constituted authority) devoted themselves to this branch of business—their charges (often exorbitant) being generally ascertained by estimate beforehand. The fees payable to the law officers were as follows: On leaving petition for grant of letters-patent, £5; on notice of intention to proceed with application, £5; on warrant of law officer for letters-patent, £5; on sealing of letters-patent, £5; on filing specifications, £5; at or before expiration of third year, £50; at or before expiration of seventh year, £100. Besides these fees, if opposition was entered to the grant, additional fees were incurred, both by the party applying and the party opposing.

At the date of the passing of the Patents, Designs, and Trade Marks Act of 1883, there were nine acts on patents more or less fully in force; and six others on copyright of designs. Now the management of this branch of the public service is put under the Science and Art Department, and the new responsible official, called the Comptroller of Patents, is an officer of the Board of Trade—from whose decisions, however, there is in certain cases an appeal to a court comprising some of the chief law officers of the crown. There is a paid examiner of patents, to whom applications are first submitted. Heretofore, seven different applications were necessary; now one suffices, and that may be sent through the post. The formulas are simplified, with the hope of enabling the patentee to dispense with the services of patent agents. In contrast with the scale of fees given above, the charges under the new law are: £1 paid down at once, when the provisional specification is lodged at the Patent Office; £3 more after nine months, when the final specification is passed by the Comptroller, and sealed; £50 after the fourth year; and £100 after the ninth. The latter two payments may be made in annual instalments. (The Board of Trade has power hereafter to reduce the fees, on obtaining the consent of the Treasury.) A register of patents is to be kept, and an Illustrated Journal of Patents officially published. Patents, as formerly, hold for 14 years, and extend to the whole of the United Kingdom.

A patent obtained in this country does not extend to the colonies, but several of the colonies have machinery for granting patents for a like period. In the United States, patents are granted for a term of 17 years. In France, the term is 5, 10, or 15 years, at the option of the applicant; in Prussia, for 15 years; in Russia, for 3, 5, or 10 years; in Spain, for 5, 10, or 15 years; in Belgium, for 20 years; in Holland, for 5, 10, or 15 years; in Austria, not more than 15 years; in Sardinia, 15 years. In all cases, fees are exigible from the patentee. See PATENT LAWS and PATENT OFFICE.

PATENT LAWS. Since the introduction of the amended Patent Law in 1852 (see PATENTS), many manufacturers have boldly advocated the abolition of the patent system altogether;

on the plea, that the good results, whatever they may be, are overbalanced by the bad. The great majority of advisers, however, call for further reform, not abolition. The Economic Section of the British Association has discussed this matter during a long series of years. The Society of Arts, also, have had many discussions on the subject; and the arguments *pro* and *con*. will be found at length in the *Transactions* of these bodies. The various Chambers of Commerce throughout the kingdom have likewise debated the subject at length. The actual operation of the system may be briefly illustrated. Mr. Bennett Woodcroft, in 1864, examined 100 patents out of those which had been applied for in 1855. Of the 100, he found 96 frivolous in character, of little or no value as to the merit of the inventions; 4 of moderate value; and not one of striking promise. Out of the 100 applications, 70 patents were granted, of which one became void at the end of six months, 51 more at the end of three years, and 15 more at the end of seven years—because the patentees declined to pay the successive instalments of fees. There were therefore, in 1863, only 3 patents left out of the 100 which had been applied for in 1855. Mr. Woodcroft finds that about the same ratio is exhibited in the whole of the 8000 or so applied for every year. In 100 of the average applications in 1858, he pronounced that there was not one invention of much value, 8 of some, and 97 of little or no value. In 1862, he found 1 of much, 1 of some, and 98 of little or no value. As to statistics of actual numbers, see PATENT OFFICE, LIBRARY AND MUSEUM.

In 1862, a royal commission was appointed to consider the whole subject of the patent laws, and to suggest alterations which might be useful. The commission collected evidence in that and the two following years, and made its Report in 1864. Other commissions and committees have made later inquiries, and offered suggestions founded on the evidence collected; but the opinions expressed, on almost every point, are most conflicting. The divided opinion of practical men has hitherto discouraged any attempt to legislate on their recommendations; and the act of 1852 remains still in force.

PATENT OFFICE LIBRARY, AND MUSEUM. The present organization of these establishments arose mainly out of the act relating to *Patents* (q. v.) passed in 1852. Rooms were rented in Southampton Buildings, London, for the office as reorganized; a superintendent of specifications was appointed; and a plan was adopted for making the system as useful to the public as possible.

The Office.—All the specifications of patents from the earliest date were examined, and minutely classified according to their contents. The patents from 1711 to 1852 were found to amount to the large number of 12,977; and the specifications of the whole of these were printed between 1853 and 1858. There were a few of earlier date, between 1617 and 1711, but none in so complete a form as to render them worth printing. The whole fill many hundred quarto volumes, with the lithographed illustrations bound in separate folio volumes. The expense of the whole undertaking—for paper, printing, and lithographing—was £92,000; the number of copies printed was small; but any single specification can be reprinted if a demand for it should arise. The next work was to utilize this immense collection by a thorough system of indexing. Three indexes were prepared—*Chronological*, *Alphabetical* (according to the names of the inventors), and *Subject-matter*. Arrangements were at the same time made for printing and indexing the specifications of all patents obtained under the new law (1852); and this has been done year by year. (The total number of patents from 1617 to 1878 exceeded 100,000.) These specifications are sold to the public at the price of paper and print, varying from 1*d.* to about 4*s.*, averaging about 8*d.* each. The printing and publishing are completed within three weeks of the time when each final specification reaches the hands of the superintendent. Any copy of any of these, if stamped and certified, is received in any court of law or equity in the kingdom, in evidence of the patent to which it relates, without the necessity of producing the original document itself.

There are generally over 4000 petitions for new patents every year; about 800 of the petitioners usually fail to give notice of their intention to proceed, and 200 more fall away before the actual sealing of the patent; so that, roughly speaking, about 3000 specifications of patents are added to the list every year. Of this number, not more than 500 to 600 over-live three years. In 1878, 5343 applications for patents were made; but 1905 of these lapsed during the year, for various reasons. The old and new specifications from 1711 to 1878, amounting to 110,334, have all been printed and published. These works are acquiring ever-increasing value as standards of reference for intending patentees. To render the new specifications equally available with those of older date, three indexes are prepared for each year's collection, of the kinds already described. There has also been prepared a reference index to the whole series. In 1871, a new plan was

adopted, of publishing weekly abridgments of the specifications of new patents: dispensing with any further alphabetical and subject-matter indexes. Besides this, abridgments have been drawn up of most of the specifications, and will be eventually of all: setting forth, in a few words, the general nature of the invention. These abridgments are collected into 12mo volumes, one or more to each class of subjects; and the volumes are sold at 6*d.* to 10*s.* each, according to their bulk. At the end of 1878, there were 115 volumes of these useful works, relating to no less than 94 groups or classes of abridgments. By reference to one of these handy volumes, or to the *Subject-matter* index, an inventor can see whether any person has preceded him in the particular subject for which he desires a patent.

The Library and Reading-room.—Special arrangements are made to render the specifications, and all that relates to them, as available as possible to the public. Complete sets of the printed specifications, indexes, &c., have been presented to universities, government offices, provincial towns, colonies, and foreign governments; and partial sets to 800 mechanics' institutes and scientific and literary societies. A complete set comprised in 1880 above 3600 volumes, from folio to 12mo, and cost no less than £2500 for paper, printing, and lithographing; about 160 of these complete sets have been presented. At the head office in Southampton Buildings, a Reading-room has been provided, open to such of the public as may wish to consult the specifications at their leisure. But besides this, the commissioners have gradually become possessed of a large and valuable collection of scientific and technical books and periodicals, to which additions are every year made by purchase. A new Library and Reading-room, occupying the upper part of the old building, has been constructed at a cost of £15,000, and was finished and opened in 1867. All the scientific and technical works of the Library of 80,000 volumes, as well as the specifications of the patents, may here be consulted.

The Museum.—The commissioners having come into possession, by gift and otherwise, of several models illustrating patented inventions, had no place of their own to deposit them for preservation and exhibition. But an arrangement was made with the authorities at South Kensington for the reception of these models; and, greatly augmented by specimens, drawings, diagrams, and portraits, the Patent Museum now occupies a site adjacent to the South Kensington Museum.

The commissioners have for many years sought permission to erect a large and handsome building to accommodate the whole of their departments—offices, Library, Reading-room, and Museum. They possess the pecuniary means, but lack the authority. Their receipts exceed £100,000 a year, in the form of fees from patentees; and after a very liberal expenditure for salaries, superannuation allowances, editing, compiling, printing, purchase of books and periodicals, &c., there is a considerable surplus. A clause in the act of 1852 prevents them from buying land and erecting buildings without the consent of the Treasury. One suggestion made by the commissioners is for permission to build in a new street to be formed from the Horse Guards to the Thames Embankment; and another is, that the new building should be on the Embankment itself, a still more prominent site.

PA'TERA (Lat.), a round dish, imitations of which were carved

Patera.

by the Romans in the panels of their ceilings, &c. The name is also applied to the foliated ornaments used in the same position.

PATERCULUS, C. VELLEIUS, a Roman historian, born about 19 B.C. He served under Tiberius, as prefect or legate in Germany, Pannonia, and Dalmatia; and in 14 A.D. was appointed prætor. He was alive in 30 A.D. P.'s claim to remembrance is his *Historia Romana*, a compendium of universal, but more particularly of Roman history, in two books. The work, as we have it, is not complete; the beginning, and a portion following the 8th chapter, being wanting. The work is, on the whole, impartial and discriminating; its style is based on that of Sallust. The *editio princeps* appeared at Basel in 1520.

PATERE'ROS, were small pieces of ordnance, now obsolete, worked on swivels; most commonly used on board ships, where they were mounted on the gunwale, and discharged showers of old nails, &c., into hostile boats.

PATERNO (anc. *Hybla Major*), a town of Catania, Sicily, 11 m. N.W. by W. from Catania, at the southern base of Mount Etna. Near P. are salt-springs and a salt-mine. Pop. (1871) 14,790.

PATER-NOSTER (Lat. 'Our Father'), called also **THE LORD'S PRAYER**, a short form of prayer suggested or prescribed by our Lord to his disciples (Matt. vi. 9—13, Luke xi. 1—4) as the model according to which, in contrast with the prayers of the Pharisees, their petitions ought to be composed. The Pater-Noster has been accepted as, by excellence, the form of Christian prayer. It formed part of all the ancient liturgies. So sacred, indeed, was its use, that it was reserved from pagans and catechumens under what is known as the Discipline of the Secret. The early fathers—Origen, Tertullian, Cyprian—refer to it in terms which show that even then it was a recognized form of private prayer. It was recited in baptism, and one of the privileges of the baptized was the use of the Pater-Noster. More than one of the fathers, and very many later writers, have devoted special treatises to the exposition of this prayer, as embracing all the fitting and legitimate objects of the prayer of a Christian. The Catechism of the Council of Trent contains a detailed exposition and commentary of it, and in all the services, not only of the Roman Missal, Breviary, Ritual, Processional, and Ordinal, but in all the occasional services prescribed from time to time, it is invariably introduced. In the Rosary (q. v.) of the Virgin Mary, it is combined with the Hail Mary (whence the larger beads of the 'Rosary' are sometimes called *Pater-Nosters*), and perhaps the most usual of the shorter devotions among Roman Catholics is the recitation of the 'Pater,' with one or more 'Ave Marias,' concluding with the Doxology. The Pater-Noster as commonly used by Protestants concludes with the clause, 'for Thine is the kingdom, and the power, and the glory for ever. Amen.' This clause is not used by Roman Catholics. Of the two gospels—that of Matthew and that of Luke—in which the prayer is contained, that of Luke has not this clause; and even in the Gospel of Matthew it is found only in the later MSS., in which it cannot be doubted that it is a modern interpolation. It was retained, however, in Luther's German translation, and in the Authorized Version, whence its use became common among Protestants.

Many polyglot collections of the Pater-Noster have been published from the 16th c. downwards, the most remarkable of which are those of John Chamberlayne in 150 languages (1715), of Conrad Gesner in 200 (1748), and that of Padre Hervaz in 307 (1787).

PATERSON, a city of New Jersey, U.S., at the falls of the Passaic River, on the Morris Canal, and New York and Erie Railway, 17 miles north-west of New York, a city with 25 corporations or firms engaged in the manufacture of silk, machine factories, paper-mills, and factories of carriages, cotton, flax, hemp, &c., to which the falls of the Passaic furnish water-power. The manufacture of locomotives is conducted on an extensive scale. The city contains county buildings, an academy, 2 banks, 6 newspapers, and 39 churches. Pop. (1870) 33,579; (1880) 50,887.

PATERSON, WILLIAM, the most celebrated, after John Law (q. v.), of the commercial schemers of the 17th c., was, like Law, a Scotchman, and was born in the parish of Tinwald, Dumfriesshire, in 1658. His early career is obscure, but before he was thirty he was a merchant, carrying on considerable transactions with the West Indies and other countries. It was he who first projected the Bank of England (incorporated in 1694), and he was one of the original directors. He is best known, however, in connection with the famous Darien Scheme (q. v.), of which he was the prime mover, and which obtained the royal sanction in 1695. This project came to ruin in a few years; but the scheming activity of P. continued unabated. When in 1701 William resolved to carry the contest with Louis XIV. into the heart of Spanish America, P. was taken into the king's confidence, and, but for that monarch's death, might have seen his dreams of Darien realized. He had a considerable hand in the union of Scotland with England, and was elected to the first united parliament by the Dumfries burghs. By a special act of parliament in 1715, he was awarded £18,241 as indemnity for his losses by the Darien Scheme; but he did not long live to enjoy it, for he died in 1719.—See *W. Paterson*, by S. Bannister (1858); *The Birthplace of W. P.*, by W. Pagan (1865).

PATHOLOGICAL ANATOMY, or the anatomy of diseased organs, is included in, but must not be confounded with pathology, as until comparatively lately was often the case. It is merely a section—although a most important section—of pathology, contributing (as Professor Vogel has well remarked) 'to practical medicine the solid materials from which to construct a basement, without having the power to erect a perfect edifice.' Pathological anatomy enables the surgeon to decide whether a suspicious tumor is malignant or of a comparatively harmless nature, and in many other ways is of the greatest importance to surgery; and although at first sight it might appear to be of small importance in relation to Therapeutics, this is not in reality the case. Scientific treatment necessarily demands an accurate knowledge of the material changes which lie at the foundation of the various morbid symptoms. Hence pathological anatomy not only forms a

portion of the positive basis of Therapeutics, but it also points out the processes by which the different altered parts may be gradually restored to their normal condition. It not merely indicates what requires healing, but in many cases also the course that must be adopted in order to aid the curative tendency of nature. It likewise serves as a check on therapeutics, exposing in a most conclusive manner, the absurdity of many pretended methods of cure. It points out, for example, that in a certain stage of inflammation of the lungs (Pneumonia) a fibrinous fluid separates from the blood, and by its coagulation renders a portion of the tissue of the lung impermeable to air; and further that it requires several days for this coagulated matter to resume the fluid condition and to be removed. If any one should assert—and such assertions have often been made—that in this stage of the disease he could apply a remedy which would cure the patient in a few hours, a very slight knowledge of pathological anatomy would show the folly of such an assertion. The best English works on this subject are Vogel's *Pathological Anatomy of the Human Body*, and Jones and Sieveking's *Manual of Pathological Anatomy*.

PATHOLOGY (from the Gr. *pathos*, disease, and *logos*, a discourse) is that department of medicine, which treats of the doctrine of morbid actions or diseases. In this country the term is so far restricted as not to include the causes, treatment, &c., of diseases, but the most eminent French and German writers regard it as equivalent to 'the Theory and Practice of Medicine,' and consider it as treating not only of the classification, causes, symptoms, and physical signs of diseases, but as also including their seat, the phenomena which precede and follow them, their progress, their duration, their modes of termination, the different forms in which they occur, their complications, the changes to which they give rise in the solids and fluids of the body, and their treatment.

PA'TMOS, a bare and rocky island in the Ægean Sea, about 45 miles in circumference. It belongs to the group called the Sporades, lies to the south of Samos, and is now called Patino, but in the middle ages *Palmosa*, although there is now only one palm-tree in the whole island. It is celebrated as the place to which the apostle John was exiled, and where he saw the visions recorded in the Book of Revelation. On the top of a mountain stands the famous monastery of 'John the Divine,' half way up to which a cave is pointed out to the traveler in which, according to tradition, the apostle received his revelations. See Ross's *Reisen auf den Griechischen Inseln des Agäischen Meeres*, and Guérin's *Description de l'Île de Patmos*, &c. (Paris, 1856).

PA'TNA, or more correctly, **PATTANA** (i. e., the town), an important trading town of Hindustan, chief town of a British district and division of the same name in Bahar, Presidency of Bengal, stands on the right bank of the Ganges, and 397 miles by land N.W. of Calcutta. The city proper, forming a quadrangle, extends a mile and a half along the river-side, and is half that extent in breadth. P. is generally supposed, however, to include the suburbs, which stretch on each side of it, on the S. bank of the Ganges. The European quarter is on the W. of the town proper. Here are a church, chapel, Roman Catholic cathedral; government offices; school; the Nabob's palace; the great tank; and several noteworthy mosques and tombs. The streets of P. are covered with mud and slime in winter, and its air is thickly impregnated with choking dust in summer. Pop. (1871) 158,900.

P., under the former name of *Padmavadi*, is supposed to have been the capital of Bahar, 419 years B.C. Here, at an early period, the English established factories, and traded in opium, rice, &c. In 1763, disputes about transit-duties arose between the Company's servants and the native government. A war ensued, resulting in the British taking possession of the district. P. was the headquarters of the Wahabi or Mussulman conspiracy in 1864. Chief seat of the opium trade; trade also in table-linen, wax-candles, toys, bird-cages, and talc-pictures.—The division of P. has an area of 23,732 sq. m., and a pop. of (1872) 13,122,743; the district, an area of 2101 sq. m., and a pop. of 1,559,638.

PATOIS (of uncertain derivation), the French term applied to corrupt dialects of a language spoken by the uneducated. See **DIALECT**.

PATON, **SIR JOSEPH NOEL**, R.S.A., one of the most distinguished living Scottish artists, was born in Dunfermline in 1823. It is understood that in early life he employed himself in making designs for the damask manufacturers of his native place, and for the muslin and lace embroiderers of Paisley. He, however, soon turned his attention to the walk of art proper, and his cartoon sketch, 'The Spirit of Religion,' gained one of the three premiums at the Westminster Hall competition in 1845. Two years thereafter, his oil-picture of 'Christ bearing the Cross,' and his 'Reconciliation of Oberon and Titania,' jointly gained the prize of £300. He subsequently executed a companion-picture to the 'Reconciliation,' entitled the 'Quarrel of Oberon and Titania;'

and both now adorn the Royal Scottish Academy's galleries in Edinburgh. These pictures made the artist's reputation. Although somewhat hard and dry in color, and without any retiring and shadowy depth, they are full of brilliant fancy; and the multitudes of figures, and the variety of fairy incident, affect the spectator much in the way that the constant sparkle of Congreve or Sheridan affects the reader. He has since painted much more simply and powerfully. 'Dante Meditating the Episode of Francesca,' was exhibited in Edinburgh in 1852; and the 'Dead Lady,' a work of great and solemn pathos, in 1854. In 1855, his great picture, 'The Pursuit of Pleasure,' was exhibited in that city, where it was much criticised and much admired. He has since painted 'Home from the Crimea,' a replica of which is in the possession of Her Majesty; and 'In Memoriam,' a scene from the Indian mutinies; and for the Association for the Promotion of the Fine Arts in Scotland, a series of picture-illustrations of the 'Dowie Dens o' Yarrow.' Among his other pictures of importance are 'Dawn: Luther at Erfurt,' 'The Fairy Raid,' 'Faith and Reason,' 'Gethsemane,' 'Christ and Mary at the Sepulchre,' 'The Man of Sorrows,' 'Mors Janna Vitæ,' 'The Spirit of Twilight,' 'Thy Will Be Done' (1879), &c. Many of his works have been engraved, and are deservedly popular. Along with his brother he illustrated Aytoun's *Lays of the Scottish Cavaliers*, and in 1864 he executed twenty illustrations of the *Ancient Mariner*. P. was appointed Queen's Limner for Scotland in 1865, received the honor of knighthood in 1867, and in 1876 was made LL.D. by Edinburgh University. He has published two volumes of poems.

PATO'NCE, **CROSS**, in Heraldry (Lat. *patens*, expanding), a cross with its terminations expanding like early vegetation or an opening blossom.

PA'TOS, **LAGO DES**. See **RIO GRAND DO SUL**.

PATRAS (ancient *Patra*, Turk. *Balıbadra*), a fortified seaport, and the most important trading town in the west of Greece, in the government of Achaia and Elis, stands on the eastern shore of the gulf of the same name, 12 miles south-south-west of Lepanto. It is overlooked by the strong citadel—on the site of the ancient Acropolis—crowning a ridge, on the southern slopes of which the ancient city, as well as the modern one before the revolution, was built. The P. of to-day stands on a level space close to the sea. The plain of P. is exceedingly valuable for the currants grown, and which are the most important export of the town. Its harbor, though protected by a mole, is unsafe, and exposed to heavy seas. Earthquakes frequently occur, and most of the houses are on that account only of one story. Capotes are made here of mixed wool and goat's hair; and, besides currants, oil, valonia, raw silk and cotton, wool, hides, wax, &c., are exported. P. is by far the most important commercial town on the continent of Greece, though it suffered severely during the Greek revolution. Pop. about 24,000.

Patra is the only one of the 'twelve cities' of Achaia which still exists as a town; but most of its relics have been swept away by earthquake and revolution.

PA'TRIA POTE'STAS is the term used to express the power which the civil law gave to the Roman father over his children, and which has been the foundation of the greatly modified paternal authority recognized in modern systems of jurisprudence. The right of a parent to control his child not come to years of discretion is a part of natural law, but the more extensive *patria potestas* of the Romans was probably a relic of those early times in which families, or tribes considered as families, led a wandering pastoral life in dread of each other, under the guidance of a chief, whom it was necessary to invest with an almost unlimited authority.

By the Roman law, the *patria potestas* was acquired naturally, by the birth of a child in wedlock, or civilly, by legitimation or adoption. An unemancipated son or daughter, a grandchild by a son, or any other descendant by males, was viewed as a part of the parent's property. In early times a father had the power of life and death over his children: by the Laws of the Twelve Tables he could sell them as slaves, or could transfer them to another family by adoption. Under the republic, the despotic authority exercised by fathers over their offspring was practically limited to a considerable extent by the censors, and several emperors issued constitutions to restrain the cruelties often perpetrated by fathers towards their children. First the right of sale, and then that of life and death was taken away. Alexander Severus restricted the right of the father to moderate chastisement, and Constantine declared that the father who should kill his son was to be held guilty of murder. By the early Roman law, the son, being in his father's power, could not acquire property for himself; his acquisitions all belonged to his father; hence he was incapable of making a testament. There were, however, particularly in later times, modes by which he could acquire *peculium*, or property which should be independent of his father. A father

might give his son property to trade on, which would be his own; and latterly a son acquired for himself whatever he gained in military service, or by the discharge of certain civil functions. In all matters belonging to the *res publicum* a son was independent of his father; he could vote at the elections, hold the most important offices of state, or command the army. He could also be a tutor, tutory being considered *munus publicum*. In later times, a son promoted to the consular dignity ceased to be under the restraints of paternal control, but, unlike an emancipated son, he retained his rights of succession. Lawful children were entitled to aliment from their parents; an obligation attached in the first instance to the father and mother, and, failing them, to the grandfather. Until the time of Justinian, illegitimate children had only a claim for support against their mother; that emperor gave them a right to demand aliment from their father.

In no modern system has the paternal power been carried so far as under the Roman law. According to the French 'Code Civile,' a child is under the authority of his parents till majority or emancipation; up to that time he cannot quit the paternal residence without leave of his father, except for enrolment in the army at 18 years of age. Majority is attained at the age of 21, but a minor is emancipated by marriage. At 15, a minor may be emancipated by his father, or, if his father be dead, by his mother, by a simple declaration before a magistrate. The father possesses somewhat extensive powers of chastisement. He may obtain a warrant to arrest his child under 16, and detain him in prison for a month; and an order may be obtained for the incarceration for six months of a child above 16, on cause shown to the satisfaction of the magistrate. Parents are entitled to the usufruct of their children's property till the age of 18 or emancipation, subject to the burdens of maintenance and education; but this right does not extend to property acquired by the industry of the children, or bequeathed by a stranger under the condition of an exclusion of parental interference.

By the law of England, a father is guardian to his lawful children in minority, though this right ceases to some extent at 14. He has the power of moderate chastisement. As guardian, he receives the rents of any real estate which the child may possess, which he must account for when majority is attained. The paternal power never extends beyond majority, and to some effect, marriage acts as an emancipation. A father may by deed appoint a guardian to such of his children as are unmarried at his death till they attain majority.

In Scotland a father has a general control over the persons of his children during pupilarity; that is, till the age of 14 in the case of sons, and 12 in the case of daughters. He may fix their place of residence, direct their education, and inflict reasonable chastisement. The limits of the *patria potestas* as regards children who have attained puberty, but are under 21 years of age, are not very exactly defined; but it seems to be understood that in ordinary circumstances minors are not entitled to choose their own place of residence in defiance of paternal authority. The father is administrator-in-law, and tutor and curator of his children, unless in the case of an estate left by a stranger and placed under separate management. This guardianship ceases on majority, or on the marriage of a daughter.

PA'TRIARCH (Gr. *patriarches*, the head of a tribe) is the name given to the heads of the families in the antediluvian period of Scripture history, and is still more familiar as the designation in Jewish history of the three progenitors of the Jewish people, Abraham, Isaac, and Jacob. In the later history of the Jews, too, after the destruction of Jerusalem, the name was used to designate the heads of the Sanhedrim, one of whom, the patriarch of the west, resided at Tiberias, in Galilee, and the other, the patriarch of the Eastern Jews, at Babylon. The most familiar use of the word, however, is in the history of the Christian church. It is the name given to the bishops of certain great Metropolitan (q. v.) Sees, who not only held rank beyond other metropolitans, but also enjoyed a jurisdiction almost identical with that of the metropolitan in his own province over all the metropolitans themselves (with their provinces) included in their district, which was called a **PATRIARCHATE**. The name patriarch originally seems to have been given commonly to bishops, or at least was certainly given in a less special sense than what it eventually assumed; nor can the date at which the title first assumed its now received use be exactly determined.

It is certain, however, that the name and the office were both recognized before the Council of Nice, at which time, as we learn from the sixth canon, the patriarchal sees, acknowledged by 'ancient customs' were three in number, Rome, Antioch, and Alexandria. After the translation of the seat of empire to Byzantium, thenceforward called Constantinople, that see, originally subject to the metropolitan of Heraclea, obtained, first metropolitan, and afterwards patriarchal rank; and eventually established a precedence over the patriarchs of Antioch and Alexandria, being second only to Rome. The contests between the

Patonce.

patriarchs of Rome and Constantinople were among the chief causes of the GREEK SCHISM (q. v.). To these four patriarchates was added a fifth, in the year 451, that of Jerusalem, which was formed out of the ancient patriarchate of Antioch. The limits of these five patriarchates can only be loosely assigned. The authority of a patriarch was, in the main, that of a metropolitan, but extended over the metropolitans themselves. He had a right to consecrate the metropolitans, and to preside over the councils of his patriarchate. After the Greek Schism, and particularly after the establishment of the Latin Kingdom of Jerusalem, Latin prelates were appointed with the title and rank of patriarch in the four great Eastern sees. It was hoped that the union of the churches, effected at the Council of Florence, would have put an end to the contest thus created; but that union proved transitory, and the double series of patriarchs has been continued to the present day. The Nestorian and Eutychian sections of the Eastern Churches, too, have each their own patriarch, and the head of that portion of the former, which in the 16th c. was reconciled with the Roman see, although known by the title of *Catholicos*, has the rank and authority of patriarch. After the separation of the Russian Church from that of Constantinople, the name and authority of the metropolitan in the end was transformed into that of patriarch. But the office was suppressed by Peter the Great.

Besides these, which are called the Greater Patriarchates, there have been others in the Western Church known by the name of Minor Patriarchates. Of these the most ancient were those of Aquileia and Grado. The latter was transferred to Venice in 1451; the former was suppressed by Benedict XIV. France also had a patriarch of Bourges; Spain, for her colonial missions, a patriarch of the Indies; and Portugal a patriarch of Lisbon. These titles, however, are little more than honorary.

In the non-united Greek Church, the ancient system of the three patriarchates of Constantinople, Antioch, and Jerusalem is nominally maintained, and the authority of the patriarchs is recognized by their own communion. But the jurisdiction-limits of the patriarch of Constantinople, who is acknowledged as the head, have been much modified. The Russo-Greek Church withdrew from him partially in the 17th, and finally in the 18th century. That of Greece proper has been practically separated since the independence of the kingdom of Greece; and some years since it formally declared its independence. The patriarchs of Jerusalem and Antioch have few followers of their own rite.

PATRIARCHAL CROSS, a cross which, like the patriarchal crosier, has its upright part crossed by two horizontal bars, the upper shorter than the lower. A cross patriarchal fimbriated or was a badge of the Knights Templars.

Patriarchal Cross.

PATRICIAN (Lat. *patricius*, from *pater*, father), a name given to the members of Roman *gentes*, of whom the *populus Romanus* consisted, and to their descendants by blood and adoption. *Patres* and *patricii* were in the early days of Rome synonymous; they were so named from the *patrocinium* which they exercised over the whole state, and all classes of whom it was composed. Niebuhr's researches have established that, until the *plebs* became a distinct order, the patricians were the entire citizens or *populus* of Rome; a select number of them were senators; and the original inhabitants, reduced to a condition of servitude, were known by the name of *clientes* or *plebs*. The amalgamation of the three tribes of Ramnes, Tities, and Luceres, gave rise to a distinction between *patres majorum gentium* and *patres minorum gentium*—the latter term being applied to families recently elevated to an equality with the old patrician class. On the establishment of the plebeians as a distinct order, sharing certain rights with the patricians, the patriciate became an aristocracy of birth, in the exclusive possession of a number of important privileges. A long struggle between the two orders ended in the attainment by the plebeians of a political equality, and the establishment of a new aristocracy of *nobles* based on wealth and office. Under Constantine, the dignity of *patricius* became a personal title; not hereditary, but conferring very high honor and certain privileges. It was created at Constantinople, and not confined to Romans or subjects of the empire, but sometimes bestowed on foreign princes. These patricians, unlike the old Roman order, were distinguished in dress and equipage from the ordinary citizens. The popes in after times conferred the same title on eminent persons and princes, including many of the German emperors. In several of the Germanic kingdoms the title of patrician was bestowed on distinguished subjects; and in some parts of Italy the hereditary nobility are still styled patricians.

PATRICK, ST., a distinguished missionary of the 5th c., commonly known as the Apostle of Ireland. There is some uncertainty as to the date and place of his birth. The year of his birth is variously assigned to the years 377 and 387, of which the latter,

if not even a later date is more probable. Of the place, it is only known for certain, from his own confession, that his father had a small farm near Bonavem Taberniæ; and in one of the ancient lives he is said to have been born at Nemthur. Arguing on these data, connected with other collateral indications, some writers assign his birthplace to the present Boulogne-sur-Mer; others to a place in the estuary of the Clyde (called from him Kilpatrick) at or near the modern Dumbarton. His father, he himself tells, was a deacon named Calpornius; his mother, according to the ancient biographers, was named Conches or Conchessa, according to some of these authorities, a sister of St. Martin of Tours. P.'s original name is said to have been Succat, Patricius being the Roman appellation by which he was known. In his 16th year he was seized, while at his father's farm of Bonavem Taberniæ, by a band of pirates, and with a number of others was carried to Ireland, and sold to a petty chief, in whose service he remained for six years; after which he succeeded in effecting his escape, and probably after a second captivity, went to France, where he became a monk, first at Tours, and afterwards in the celebrated monastery of Lerins. In the year 431 he went to Rome, whence he was sent by the pope of the day, Celestine, to preach in Ireland; Palladius, who had been sent as missionary to that country a short time before, having died.

Such is the received account of his mission; but Dr. Todd, his latest biographer regards this statement as erroneous, and fixes the date of his coming to Ireland eight years later. He was ordained in France, and arrived in Ireland in 432. His mission was eminently successful. He adopted the expedient of addressing himself first to the chiefs, and of improving, as far as possible, the spirit of clauship, and other existing usages of the Irish for the furtherance of his preaching; nor can it be doubted that he had much success in Christianizing the ancient Irish system of belief and of practice. By degrees he visited a large portion of the kingdom, and baptized great numbers as well of the chieftains as of the people. According to the accounts of his Irish biographers, he founded 865 churches, and baptized with his own hand 12,000 persons. He is said also to have ordained a vast number of priests, and to have blessed very many monks and nuns. After he had been about 20 years engaged in his missionary enterprise, he is said to have fixed his see at Armagh about the year 454; and having procured two of his disciples to be ordained bishops, he held probably more than one synod, the decrees of which have been a subject of much controversy. He died at a place called Saul, near Downpatrick; and his relics were preserved at Downpatrick down to the period of the Reformation. The place is still venerated by the people. The date of his death is much disputed; the Bollandists placing it in 460, while Ussher holds it to have been 493. Dr. Todd inclines strongly to the latter opinion, in which case P.'s age would have been 126, or at least 116.

The only certainly authentic literary remains of St. P. are his 'Confession' and a letter, both of very rude Latinity, but of much historical interest. The letter is addressed to Coroticus, who is supposed to have been a Welsh chieftain named Caradoc (from whom Cardigan is named), who had made a descent on the Irish coast, and slain or carried off, with circumstances of great cruelty, a number of the Irish, many of whom were neophytes. These, with some other remains ascribed to him, as also decrees of synods, were published in Wilkins's *Concilia*, and separately by Ware, *Opuscula S. Patricii Adscripta* (1656) and by Villanueva (Dublin, 1835). The latest biography of St. P. is that of the Rev. J. H. Todd, 1 vol. 8vo. (Dublin, 1863.)

PATRICK, ST., ORDER OF, a national order of knighthood for Ireland, established by George III. on the 5th of February 1788, and enlarged in 1833. As originally constituted it consisted of the Sovereign, the Grand-master, (who was always the lord-lieutenant of Ireland for the time being) and 15 Knights. By the statutes of 1833 the number of knights was increased to 22.

The *Collar* of the order (of gold) is composed of roses alternating with harps, tied together with a knot of gold, the roses being alternately white within red, and red within white, and in the center is an imperial crown surmounting a harp of gold, from which the badge is suspended. The *Badge*, or *Jewel*, is of gold and oval; surrounding it is a wreath of shamrock proper on a gold field; within this is a band of sky-blue enamel charged with the motto of the order, *QUIS SEPARABIT MDCLXXXIII.* in gold letters; and within this band a saltire gules (the cross of St. Patrick), surmounted by a shamrock or trefoil slipped vert, having on each of its leaves an imperial crown or. The field of the cross is either argent, or pierced and left open.

A sky-blue *Ribbon*, worn over the right shoulder, sustains the badge when the collar is not worn. The *STAR*, worn on the left side, differs from the badge only in being circular in place of oval, and in substituting for the exterior wreath of shamrocks eight rays of silver, four of which are larger than the other four. The *MANTLE* is of rich sky-blue tawny, lined with white silk, and fastened by a cordon of blue silk and gold with tassels. On

the right shoulder is the HOOD, of the same materials as the mantle.

The order is indicated by the initials K. P.

Order of St. Patrick.

PATRIPASSIANS (Lat. *pater*, father, and *passus*, suffered), the name of one of the earliest classes of anti-Trinitarian sectaries, who, in maintaining the oneness of the Godhead, held that all that is ascribed in the Scriptures, according to the Trinitarian exposition, to any of the Three Persons, is in reality true of the one Principle, whom alone these sectaries admitted, being in consequence called 'Monarchians' (Gr. *monos*, one, and *arche*, principle). The leader of this sect was Praxeas, a native of Phrygia, who lived in the end of the 2d century. The name P., for which the Greek equivalent was *Patropaschites*, was in some sense a sobriquet, being founded on what their antagonists regarded as the absurd consequence derivable from their doctrine—viz., that as it was true to say that Jesus, in whom dwelt the Logos, or the Son, suffered, therefore it would be true on their principles to say that the Father suffered. The sect in this particular form was chiefly known in Rome; but their principles are in the main the same with those of the Sabellians. In Rome, Praxeas was succeeded by Noetus, but the party does not appear to have been numerous or influential.

PATRO'CLUS. See **ACHILLES**.

PATRO'CL is a detachment of five or six soldiers, fully armed, sent out, under a sergeant, from the main guard or picket to traverse the streets of a garrison town, &c., and arrest disorderly persons or soldiers out of barrack without proper passes. Prisoners are taken to the guard-house, and brought before the town-major. In a besieged fortress, *patrols* are strong bodies of men employed to promenade the lines of defence, and watch against any assaults on the part of the enemy.

PA'TRON (Lat. *patronus*, from *pater*, father), among the Romans originally signified a citizen who had dependents, who were called *clients*, attached to him. Before the time of the Laws of the Twelve Tables, the most frequent use of the term *patronus* was in opposition to *libertus*, these two words being used to signify persons who stood to one another in the relation of master and manumitted slave. The Roman was not denuded of all right in his slave when he freed him; a tie remained somewhat like that of parent and child, and the law recognized important obligations on the part of the *libertus* towards his patron, the neglect of which involved severe punishment. In some cases the patron could claim a right to the whole or part of the property of his freed man. The original idea of a patron apart from the manumitter of slaves continued to exist. A Roman citizen, desirous of a protector, might attach himself to a patron, whose client he thenceforward became; and distinguished Romans were sometimes patrons of dependent states or cities, particularly where they had been the means of bringing them into subjection. Thus the Marcelli were patrons of the Sicilians, because Claudius Marcellus had conquered Syracuse and Sicily.

The patron was the guardian of his client's interest, public and private; as his legal adviser, he vindicated his rights before the courts of law. The client was bound, on various occasions, to assist the patron with money, as by paying the costs of his suits, contributing to the marriage portions of his daughters, and de-

fraying in part the expenses incurred in the discharge of public functions. Patron and client were under an obligation never to accuse one another; to violate this law amounted to the crime of treason, and any one was at liberty to slay the offender with impunity. One obvious effect of the institution of *clientela* was the introduction of an element of union between classes of citizens who were otherwise continually brought into opposition to each other. As the patron was in the habit of appearing in support of his clients in courts of justice, the word *patronus* acquired, in course of time, the signification of advocate or legal adviser and defender, the client being the party defended; hence the modern relation between counsel and client.—*Patron*, in after times, became a common designation of every protector or powerful promoter of the interests of another; and the saints, who were believed to watch over the interests of particular persons, places, trades, &c., acquired in the middle ages the designation of their patron saints. The saint in whose name a church is founded, is considered its patron saint.

The term Patron has also been applied to those who endowed or supported churches and convents. See **PATRONAGE ECCLESIASTICAL**.

PA'TRONAGE, ECCLESIASTICAL, the right of presenting a fit person to a vacant ecclesiastical benefice. The patron, in the original and more strict sense, was the person who founded or endowed the church. In the early ages of Christianity, the countries where the new religion had been adopted were parcelled out into large districts or dioceses, under the superintendence of a bishop, who usually resided in the neighborhood of one of the religious houses. Within such district the bishop had the nomination of the priests, who supplied religious instruction to the people. The priests were paid out of the episcopal treasury, and traveled about in the exercise of their duties, having their residence with the bishop, and forming that *episcopi clerus* which constituted the notion of cathedral churches and monasteries in their simplest form. Occasionally a bishop endowed a church in his diocese, and attached a priest permanently to it; and in Gaul, in the 5th c., a bishop who founded a church in a neighboring diocese was allowed to appoint an incumbent of his choice. As Christianity became more universal, and the population increased, the means of worship supplied by the bishoprics, the monasteries, and occasional episcopally endowed churches, became inadequate for the demands of the people, and the proprietors of lands began to build and endow churches in their own possessions. In such cases the chaplain or priest was not paid by the bishop, but allowed to receive for his maintenance, and for the use of his church, the whole or a part of the profits of the lands with which the founder had endowed it, and the offerings of those who frequented the church for worship. A district was defined by the founder, within which the functions of the officiating priest were to be exercised; and both the burden and the advantages of his ministry were limited to the inhabitants of that district.

As these pious foundations tended both to the advancement of religion and to the relief of the episcopal treasury, they were encouraged by the bishops, who readily consecrated the churches thus established, and consented that the incumbent should be resident at the church, and receive the tithes and offerings of the inhabitants and what endowment the founder had annexed to the church. Eventually, it came also to be stipulated with the bishop that the founder and his heirs should have a share in the administration of the property, and have the right to nominate a person in holy orders to be the officiating minister whenever a vacancy occurred. It also became a not unusual arrangement that when owners of estates rebuilt such churches as were dependent on the cathedral, or undertook to pay the incumbent, to the relief of the cathedral, the right of presentation was transferred from the bishop to these persons, who thenceforward stood in the same relation to these churches as if they had been the original founders. Out of these private endowments arose the parochial divisions of a later time, which thus owe their origin rather to accidental and private donation than to any legislative scheme for the ecclesiastical subdivision of the country. The bounds of a parish were at first generally commensurate with those of a manor, and the lord of the manor was the hereditary patron. The person enjoying the privileges of a founder was called *patronus* and *advocatus*. He had a pre-eminent seat and a burial-place in the church; he enjoyed a precedence among the clergy in processions; his name and arms were engraved on the church and on the church-bells, and he was specially named in the public prayers. He had the right to a certain portion of the church funds, called *patronagium*, and enjoyed the fruits of the benefice during a vacancy.

In the course of time it sometimes happened that, with the concurrence of all parties interested, the patronage, and the church with its revenues and appurtenances, were made over to a religious house, which thus became both patron and perpetual incum-

bent of the parish, while the immediate duties of the cure were devolved on a vicar or stipendiary curate. In France, the right of patronage was often extended to churches not originally private foundations by the necessities of the sovereigns, which led them to take possession of church property, and bestow it in fee on laymen, who appropriated the greater part of the revenues, and took the appointment of the clergy into their own hands. For a length of time, not merely the nomination but the investiture of the clergy came to be exercised by lay patrons, a state of matters which roused the indignation of successive popes and councils: until it was at last ruled by the third and fourth Lateran Councils (1179 and 1215 A.D.) that the presentation of the patron should not of itself suffice to confer any ecclesiastical benefice, even when qualified by the discretionary power of rejection given to the bishop, when the presentee was a layman. It was declared necessary that the presentee should not merely have the temporalities of the benefice conferred on him by induction, but also be invested with the spiritualities by institution.

When the bishop was patron of the benefice, the ceremonies of induction and institution were united in that of collation. With the growth of the papal power, however, a practice arose by which the right of presentation or induction, which had nominally been left to the patrons, became in some degree nugatory. Towards the close of the 12th c., letters of request, called mandates or expectatives, began to be issued by the popes to patrons, praying that benefices should be bestowed on particular persons. What had at first been requested as a favor was soon demanded as a right, and a code of rules was laid down with regard to grants and revocations of expectatives. In the 18th c. the patronage of all livings whose incumbents had died at the court of Rome (*vacantia in curia*) was claimed by the pope; and as ecclesiastics of all ranks from every part of Europe frequently visited Rome, the number of benefices *vacantia in curia* was always very great. Clement V. went so far as broadly to declare that the pope possessed the full and free disposal of all ecclesiastical benefices. The practice next arose of the pope making reversionary grants, called provisions of benefices, during the lifetime of the incumbent, and reserving what benefices he thought fit for his private patronage. By means of permissions to hold benefices *in commendam*, and dispensations for non-residence and holding of pluralities, upwards of fifty benefices were often held by one person; and throughout all Europe the principal benefices were filled by Italian priests, nominees of the popes, who were often ignorant of the very language of the people among whom they ministered.

In the 14th c. these claims encountered much opposition. England took the lead in an organized resistance, which was in the end successful. A series of English statutes was passed, beginning with the Statute of Provisors, 25 Edw. III., c. 6, solemnly vindicating the rights of ecclesiastical patronage, and subjecting to severe penalties (see PRÆMUNIRE) all persons who should attempt to enforce the authority of papal provisions in England. The principles adopted by the third and fourth Lateran Councils have since been substantially the law of patronage in Roman Catholic countries. A lay patron is, by the canon law, bound to exercise his right of presentation within four, and an ecclesiastical patron within six months, failing which the right to present accrues *jure devoluto* to the bishop of the diocese. Patronage has always been more or less subject to alienation, transmission, and the changes incident to other kinds of property. The modern practice of patronage in the Roman Catholic church is detailed under the head PROVISION (q. v.).

In England, where the modified canon law, which was in use before the Reformation, is still in force, the rights of patrons do not materially differ from those which they possess in Roman Catholic countries. For some details regarding the right of presentation in England, see ADVOWSON.

In Scotland, at the Reformation, the rights of patrons were reserved, and presbyteries were bound by several statutes to admit any qualified person presented by the patron. The principle of these statutes was retained in the enactments introducing Episcopacy. On the establishment of Presbytery under favor of the civil war, patronage was abolished by act 1649, c. 23, and the election of the clergy was committed to the kirk-session. At the Restoration, this statute fell under the act rescissory, and patronage was replaced on its former footing. On the reintroduction of Presbytery at the Revolution, patronage was again cancelled, and the right to present conferred on the Protestant heritors and the elders of the parish, subject to the approval or rejection of the whole congregation. In consideration of being deprived of the right of presentation, patrons were to receive from the parish a compensation of 600 merks (£33, 6s. sterling), on payment of which they were to execute a formal renunciation of their rights. Only three parishes effected this arrangement with the patron, and patronage was permanently restored in all the parishes where no renunciation had been granted by 10 Anne, c. 12. This act, with modifications introduced by 2 and 7 Vict. c. 61, was law till

1874. If a patron failed to present for six months after the occurrence of a vacancy, the right to present fell to the presbytery *jure devoluto*. The presentee, before he acquired a right to the emoluments of the benefice, required to be admitted to it by the presbytery of the bounds. He was first appointed to preach certain trial sermons, after which a day was fixed within six weeks for moderating in his call. On that day the people were invited to sign a written call to the presentee to be their minister, and however few the signatures to the call might be, the presbytery were in use to pronounce a formal judgment sustaining it. They then proceeded to examine into the qualifications of the presentee, and provided the result were satisfactory, the ordination followed (if he had not been previously ordained), and he was formally admitted minister of the parish by the presiding minister.

Soon after the above-mentioned act of Queen Anne, a feeling which had sprung up in favor of popular election, in opposition to patronage, led to various acts of resistance to the settlement of presentees, and brought about two considerable secessions from the Church of Scotland. It continued for a length of time to be a subject of dispute how far the right of the church to judge of the fitness of presentees could entitle her to make rules tending to disqualify them, and in particular whether she could legally make the dissatisfaction of the congregation a disqualification. For a long time prior to 1834, there had been no attempt to give effect to any dissent on the part of the congregation. In that year the law of patronage again became a ground of contention, when a majority of the General Assembly embodied their views on the subject in the so-called Veto Act, which declared that no minister was to be imposed on a congregation when a majority of heads of families and communicants should dissent from his admission. The decision of the Court of Session, confirmed by the House of Lords, finding this act to be *ultra vires* of the General Assembly, led to the secession of 1843 and formation of the *Free Church* (q. v.). After that event, an act, 6 and 7 Vict. c. 71, commonly called Lord Aberdeen's Act, was passed to fix by a legislative provision the effect which the church courts were in future to be entitled to give to the dissent of the congregation in the collation of ministers. It was there enacted, that after the trial sermons, the presbytery should give to the parishioners, being members of the congregation, an opportunity to state objections which did not infer matter of charge to be proceeded against according to the discipline of the church. The presbytery were either to dispose of the objections, or to refer them to the superior church judicatory; and if they were considered well founded, the presbytery might reject the presentee. No power was given to reject him on the ground of mere dislike by any portion of the congregation.

By an act of parliament in 1874, patronage was abolished, and the right of choosing their minister transferred to the congregation, provision being made to compensate the previous patron to the extent of one year's stipend of the parish.

In the Protestant churches of Germany, Sweden, and Denmark, patronage exists to some extent, subject to restrictions, which differ much in different localities. The right to present is sometimes divided between the patron and the consistory. The parishioners have in many instances a voice; the appointment may be entirely in their hands, or they may have merely a right to reject the presentee after he has been subjected to the ordeal of a trial sermon; and in either case this right may be exercised, according to local usage, either by the parishioners at large, by a committee of their number, or by the bürgermeister. When there is no patron, the choice generally rests with the consistory in East, and with the parishioners in West Germany. Induction by the superintendent completes the right of the presentee.

In the Greek Church the right to present is generally in the hands of the bishops, excepting in Russia, where lay patronage exists to a limited extent.

PATRONYMIC (Gr, *pater*, father, and *onoma*, name), properly a name taken from one's father, but generally applied to such names as express descent from a parent or ancestor. In Sanskrit, Greek, and Latin, patronymics are very numerous. They may be derived from the name of a father, mother, grandfather, or remoter ancestor, as Atrides, i. e., (Agamemnon), son of Atreus; Philyrides, i. e., (Chiron), son of Philyræ; Æacides, i. e., (Achilles), grandson of Æacus. The names of the founders of nations have also been used to form a sort of patronymic, as when the Romans are called Romulidæ. In Greek and Latin the commonest termination of patronymics are *ides* and *is*. Patronymics have no fewer than thirteen recognized terminations in Sanskrit. A number of the surnames in use in modern times are patronymics, as Johnson, the son of John; Thomson, the son of Thomas.

Originally these names fluctuated from generation to generation, as still is, or very recently was, the case in Shetland, where Magnus Johnson's son calls himself John Magnusson or Manson. In the course of time, it was generally found more convenient to take a surname from one well-known ancestor, which should de-

scend unchanged to the children of the bearer of it. The termination *s* is sometimes used as equivalent to son, as in Jones, Rodgers. To patronymics belong Norman, Highland, Irish, and Welsh surnames with the prefixes *Fitz*, *Mac*, *O*, and *Ap*, respectively. In many cases the *Mac* of the Highlands of Scotland ceased to have a fluctuating character only a few generations ago. In 1465, an act of the parliament of Ireland was directed against the use of patronymics. Every Irishman 'dwelling betwixt or among Englishmen in the counties of Dublin, Myeth, Uriel, or Kildare,' was ordered 'to take to him an English surname of a town, as Sutton, Chester, Trym, Skryne, Corke, Kin-sale; or color, as White, Blacke; or arte or science, as Smith or Carpenter; or office, as Cooke or Butler; and that he and his issue should use the same.' In Wales it was long the practice to use a string of ancestral names, each with the syllable *Ap* prefixed to it. Camden relates that 'in the time of King Henry VIII. an ancient worshipful gentleman of Wales being called at the pannell of a jury by the name of Thomas Ap William Ap Thomas Ap Richard Ap Hoel Ap Evan Vaghan, &c., was advised by the judge to leave that old manner; whereupon he afterwards called himself Moston, according to the name of his principal house, and left that surname to his posteritie.' See NAME.

Pattee.

PATTEE, Cross, in Heraldry (Lat. *patulus*, spreading), also called Cross Formée, a cross with its arms expanding towards the ends, and flat at their outer edges.

PATTI, ADELINA MARIA CLORINDA, a popular operatic singer of Italian extraction, born at Madrid April 9, 1843. After a course of professional study, she sang at an early age in New York. Her *début* in London took place in 1861 as Amina in *La Sonnambula*; and she has ever since been looked upon as one of the first singers of the day. Her voice is an unusually high soprano, of rich bell-like quality, and remarkable evenness of tone; to these qualities she adds purity of style and high artistic finish. Equally at home in the tenderness of deep passion and the sprightly vivacity of light comedy, she has also sung with success in oratorio. She has also won golden opinions on the continent wherever she has appeared, receiving, in 1870, the Order of Merit from the Emperor of Russia. Her greatest success is generally considered to be in the part of Marguerite in Gounod's *Faust*. In May 1868, she married the Marquis de Caux, from whom she was divorced in 1876. She had never retired from the stage.

PATTI, CARLOTTA, sister of the above, is also one of the leading singers of the day, though a slight degree of lameness has prevented her from appearing much in opera. Her voice is a soprano of unusual compass, and of a clear silvery quality, and much power in the upper register. Her peculiarly high notes, and a graceful *abandon* of manner, have brought her into favor with the public, though, in quality of tone, she does not come up to her sister. She made her *début* in London in 1862, but had for some time before been in the enjoyment of a high reputation in the United States.

PATUXENT, a river of Maryland, U. S., rises 20 miles east of Frederick City, and after a south-easterly course of 90 miles, empties by a broad estuary into Chesapeake Bay.

PAU, a flourishing town of France, capital of the department of Basses-Pyrénées, on the right bank of the Gave-de-Pau, 105 miles south-south-east of Bordeaux. It occupies a rocky height, cloven into two portions by a ravine through which a streamlet flows into the Gave-de-Pau, and united by a high bridge. Toward the south it commands most magnificent views of the Western Pyrénées; indeed, for mountain views its situation is hardly surpassed by that of any town in France. As seen from this town, the distant Pyrénées rise in peaks, cones, and serrated ridges, and present an outline as varied as it is strikingly beautiful. The town contains a palace of justice, a promenade, Royal Square, with a bronze statue of Henri IV., beautiful theater, university-academy, museum, and library of 25,000 vols. Linen and cloth manufactures are the chief branches of industry; in the vicinity, Jurançon wine (good but strong) is grown. Many swine are fed in the vicinity, and from the pork the famous *Jambons de Bayonne* are made. Pau is a favorite resort of the English, especially during winter, and is a general rendezvous for those who wish to explore the Pyrénées. Pop. (1876) 27,553.

The principal building, however, of Pau, and that to which it owes its existence, is the old castle which stands on the ridge overlooking the river, and forms both the most conspicuous and most interesting feature of the town. It has five towers, united by an outer wall, and is supposed to have been founded by Gaston de Foix about the year 1363. Pau was the capital of the kingdom of Bearn, and its castle was the birthplace of the famous Henri IV.

PAUCH'ONTI TREE (*Isonandra polyandra*), a large forest-tree, of the same genus with the gutta-percha tree, and producing a substance similar to gutta-percha, abundant in some of the forests at the base of the Western Ghauts in India. It is now supposed that there are several species of *Isonandra* in Western India, the produce of all which has begun to be sent to the market as gutta-percha, although it is said that none of the kinds is equal in quality to the true gutta-percha, obtained from *Isonandra gutta*. The wood of the P. tree is very heavy, and its tenacity is equal to that of teak. A P. tree having been tapped in 40 places, from the base to 60 feet high, has yielded in twelve hours about eight pints of sap, each pint being equal to about a pound of gutta-percha.

PAUL, the great apostle of the Gentiles, was born of Jewish parents at Tarsus, in Cilicia, and inherited from them the rights of Roman citizenship. His original name was Saul. He was educated first in his native city, then in the zenith of its reputation for its schools of literature and philosophy, where he doubtless learned to speak and write Greek; and afterwards, to be perfected 'in the law of his fathers,' was sent to Jerusalem, where he studied under Gamaliel, a great Jewish doctor, and became one of the strictest, most zealous, and most ardent Pharisees. Whether it was here or at Tarsus that he acquired his knowledge—which we have no reason to believe was ever very deep—of the philosophy and literature of Greece, cannot be ascertained. According to the wholesome rule observed among the Jews, that every person should learn some trade, Saul became a tent-maker, and at this trade he afterwards labored (Acts xviii. 3) for his support. A few years after the death of Jesus, he became as might have been expected from his training and temperament, a furious adversary of the new sect of Christians.

We are told (Acts vi. 9) that the Jews of the Cilician synagogue at Jerusalem were among those who disputed with Stephen, and it is natural to suppose that the young and brilliant zealot, eager for disputation, was conspicuous among the crowd of Jewish students who poured out of their synagogues (of which, according to the Talmud, there were 480 in the holy city), in the insolence of their youth and scholarship, to crush the ignorant followers of the Nazarene. This supposition is rendered highly probable by the fact, that he was present at the martyrdom of Stephen, which followed almost immediately, having charge of the raiment of them that slew him. He now became a prominent actor in the great persecution of the Christians that broke out at Jerusalem. The mysterious circumstances that led to and attended his conversion are familiar to all readers of the Acts of the Apostles, and need not be recapitulated here. After a solitary sojourn in Arabia—perhaps to calm his perturbed spirit in communion with God, and to solemnly prepare himself for his new mode of life—on his return to Damascus, he changed his name to Paul, and resumed or began (it is not quite clear which) his apostolic labors. Naturally, he became an object of intense hostility to the unbelieving Jews in that city. They resolved to kill him; but his friends contrived a way of escape, and he fled to Jerusalem, where at first he was received with suspicion by the disciples, but afterwards, through the kind offices of Barnabas, with great cordiality. He now 'spoke boldly in the name of Christ,' disputing also against the 'Grecians'—i. e., the Hellenistic Jews—with dangerous success, for his opponents sought to take his life. Again he was obliged to flee, and betook himself to his birthplace, Tarsus, where he seems to have remained till Barnabas brought him to Antioch (not far off), to assist in the great work of evangelization going on in that city.

After a short visit to Jerusalem in the year of the famine, 44 A.D., they were set apart by the prophets and elders of the church at Antioch for the evangelization of the more distant Jews. From Seleucia they proceed on their first missionary expedition to the southern districts of Asia Minor, Pamphylia, Pisidia, and Lycaonia, where they met, especially in some places, with considerable success, in preaching the gospel. It is very interesting to notice how gradually the light of Christianity dawned on the mind of the apostle. He did not grasp all at once its grand design. It was not even by abstract reflection that he arrived at it. Circumstances of quite an outward sort forced him to the sublime conclusions of his creed. It was when the Jews of Pisidian Antioch, enraged at his preaching the gospel indiscriminately to their Gentile fellow-townsmen and themselves, 'contradicted and blasphemed' him, that he boldly announced Christ as the universal Redeemer. After the return of P. and Barnabas to Antioch, they continued to labor in that city for a long time, till dissensions having arisen about the circumcision of Gentile converts, he, along with Barnabas and others, was chosen to go up to Jerusalem, to get the opinion of the apostles and elders there on the question, about 51 A.D. P. and Barnabas now returned to Antioch, where they continued to teach and preach, till a yearning grew up in the heart of the former to revisit his Gentile converts in Asia Minor. In his second expedition, P. was accompanied by

Silas instead of Barnabas, and traversed the whole of Asia Minor from south to north, evangelizing with great success, after which the two missionaries crossed the *Ægean* and landed in Europe, planting at Philippi, the capital of Thracian Macedonia, the first Christian Church in that continent. The details of his visits to Thessalonica, Berea, Athens, and Corinth are, doubtless, familiar to our readers, and need not be given here. We can only notice his appearance at Athens, where, on Mars' Hill, before a crowd of the citizens, among whom were Epicurean and Stoic philosophers, he delivered that magnificent discourse in which he declared to the Athenians the character of the 'unknown' God.

On his return to Asia Minor he visited Ephesus, where, as usual, he 'reasoned' with the Jews in their synagogue; sailed thence to Cæsarea, in Palestine, and proceeded to Jerusalem 'to keep the feast,' after which he again returned to Antioch, the center from which his operations radiated. Thus closed his *second* evangelistic journey.—The third journey of P. commenced probably about 54 A.D., and extended over much the same district as the previous one. At Ephesus, where he remained for a period of two years and three months, his efforts were powerfully seconded by the eloquence of the great Alexandrian convert, Apollos. Here it is recorded (Acts. xix.) that 'God wrought special miracles by the hand of Paul, so that from his body were brought unto the sick handkerchiefs or aprons, and the diseases departed from them, and the evil spirits went out of them.' In explanation of this very curious procedure, which has a disagreeable resemblance to ordinary legerdomain, it has been suggested, that as Ephesus was a city noted for its exorcisms, spells, and incantations—the famous *Ephesia Grammata* sold at a high price to the ignorant and superstitious populace—this style of miracle was an accommodation to their belief in magic and dæmonism, and intended to show them, according to their own way of regarding things, the superiority of Christ's power to that of the evil spirits of heathen worship. From Ephesus, P. went up to Jerusalem with a presentiment that heavy evils were about to fall upon him through the ever-maddening malice of the Jews. The Jewish populace were goaded into the wildest fury by the very sight of Paul.

The captain of the Roman guard, Claudius Lysias, had to interfere to save him from being torn to pieces; but as forty Pharisees had sworn neither to eat nor drink till they had taken his life, he was sent by night, under a strong escort, to the Roman governor, Felix, at Cæsarea, where he was unjustly detained a prisoner for two years. Having finally appealed to the Roman emperor, according to the privilege of a Roman citizen, he was sent to Rome. On the voyage thither, he suffered shipwreck at Melita (probably Malta), in the spring of 61 A.D. At Rome, he was treated with respect, being allowed to dwell 'for two whole years in his own hired house.' His first thoughts were, as usual, directed towards his Jewish brethren in the city; but, on the whole, he made little impression on them. Whether he ever left the city or not, cannot be positively demonstrated, but it is believed by many critics, from a variety of considerations, that he did obtain his liberty about 64 A.D., and that he made journeys both to the east and to the west, revisiting Asia Minor, and carrying out his long-cherished wish of preaching the gospel in Spain. Meanwhile occurred the mysterious burning of Rome, generally attributed to Nero, who threw the blame on the Christians, and in consequence, subjected them to a severe persecution. Among the victims was P., who, according to tradition, suffered 67 A.D.—See *Life and Epistles of St. P.*, by Conybeare and Howson; Baur's *Paulus*; Lipsius, *Der Apostel Paulus* (1869); Renan, *Saint Paul* (1869); Pfeiderer, *Der Paulinismus* (1873; trans. 1878); Farrar, *St. Paul*, (2 vols. 1879.)

PAUL was the name of five popes. PAUL I. (757—768 A.D.) and PAUL II. (1464—1471) were unimportant.—PAUL III., pope at a critical time, was originally named Alessandro Farnese, and was born at Carino, in Tuscany, in 1468. Having been created cardinal, he served in several important trusts, and eventually became bishop of Ostia and Dean of the Sacred College. On the death of Clement VII., in 1534, he was elected pope, just at the crisis when the world was alive with expectation of the general council which was to decide all the controversies at that time agitating the public mind of Europe. After some delays, P. convoked the council to meet at Mantua in 1542; but it did not actually assemble (in Trent) until 1545. These delays are by some charged upon P.; but it can hardly be doubted that much of it was due to the difficulties of the times. The bull of excommunication and deposition which he issued in 1538 against Henry VIII. of England, is one of the last examples of the exercise of the temporal power claimed by the mediæval popes. In the contest of Charles V. with the Protestant League in Germany, P. sent a large force to support him, and he opposed the pacification proposed by the emperor upon the basis of the INTERIM (q.v.). P.'s conduct in aggrandizing the fortune of his son, Pietro Luigi Farnese, has been severely criticised by historians; the more so, that his son was born out of wedlock, in the early youth of his

father. P. died November 10, 1549, in his 82d year.—PAUL IV., named John Peter Caraffa, a member of the noble family of that name, was born in Naples in 1476. His early career was distinguished for ascetic rigor. He was appointed Bishop of Chieti, in which see he labored most earnestly for the reformation of abuses, and for the revival of religion and morality. With this view, he established, in conjunction with several congenial reformers, the congregation of secular clergy called *THEATINES* (q.v.), and was himself the first superior. It was under his influence that Paul III. organized the tribunal of the Inquisition in Rome.

On the death of Marcellus II. in 1555, although in his seventy-ninth year, he was elected to succeed. He entered upon the wider career of reformation which his new position opened for him with all the ardor of a young man, and with all the stern enthusiasm which had characterized him during life. He enforced vigorously upon the clergy the observance of all the clerical duties, and enacted laws for the maintenance of public morality. He established a censorship, and completed the organization of the Roman Inquisition; he took measures for the alleviation of the burdens of the poorer classes, and for the better administration of justice, not sparing even his own nephews, whom he banished from Rome, on account of their corrupt conduct and profligate life. His foreign relations, too, involved him in much labor and perplexity. He was embroiled with the Emperor Ferdinand, with Philip II. of Spain, with Cosmo, Grand Duke of Tuscany. Having condemned the principles of the Peace of Augsburg, he protested against its provisions. Under the weight of so many cares, his great age gave way. He died August 18, 1559, in his 84th year. At his death, the populace broke out into an insurrectionary tumult, which lasted till the conclave for the appointment of his successor.—PAUL V., originally named Camillo Borghese, was born in Rome in 1552. In his early life, he was a distinguished canonist and theologian; and after the ordinary prelatical career at Rome, he rose first to the post of nuncio at the Spanish court, and afterwards to the cardinalate under Clement VIII. On the death of Leo XI. in 1605, Cardinal Borghese was elected to succeed him. His pontificate is rendered memorable by the celebrated conflict with the republic of Venice, into which he was plunged at the very outset of his career.

The original ground of dispute was the question of the immunity from the jurisdiction of civil tribunals conceded to the clergy, who claimed to be tried by ecclesiastical tribunals alone. This claim the senate resisted; and further causes of dispute were added by a mortmain law, and a law prohibiting the establishment of new religious orders or associations unless with the sanction of the senate. Each party remaining inflexible in its determination, P. issued a brief, directing a sentence of excommunication against the doge and senate, and placing the republic under an interdict, unless submission should be made within twenty-four days. The senate persisted, and an animated conflict, as well of acts as of writing ensued, in the latter of which the celebrated Fra Paolo Sarpi, on the side of the republic, and on the papal side, Bellarmine and Baronius, were the leaders. Preparations were even made for actual hostilities; but, by the intervention of Henry IV. of France, the dispute was accommodated, and peace restored in 1607, although dissatisfaction afterwards arose on the subject of the nomination of a patriarch. A misunderstanding of a similar nature arose between the pope and the crown in France as to the rights of censorship on books, and as to the receiving of the disciplinary decrees of the Council of Trent; but it was removed by mutual explanations. His administration was vigorous and enlightened, and he did a great deal for the promotion of useful public works, for the embellishment of the city, the restoration and preservation of antiquities, the improvement of the museums and libraries, and, above all, for the pious and charitable institutions of Rome. P. died in his 69th year, January 28, 1621.

PAUL, VINCENT DE, one of the most eminent saints of the modern Catholic Church, was born of humble parentage at Rancun, in the diocese of Dax, in the year 1576. The indications of ability which he exhibited led to his being sent to school at Toulouse. He became an ecclesiastical student, and was admitted to priest's orders in 1600. On a voyage which he was making from Marseille to Narbonne, his ship was captured by corsairs, and he with his companions sold into slavery at Tunis, where he passed through the hands of three different masters. The last of these, who was a renegade Savoyard, yielded to the exhortations of Vincent, resolved to return to the Christian faith, and with Vincent, made his escape from Barbary. They landed in France in 1607. Having gone thence to Rome, he was intrusted with an important mission to the French court in 1608, and continued for some time to reside in Paris as the almoner of Marguerite de Valois. The accident of his becoming preceptor of the children of M. de Gondy, the commandant of the galleys at Marseille, led to his being appointed almoner-general of the galleys in

1619. It was at this time that the well-known incident occurred of his offering himself, and being accepted, in the place of one of the convicts, whom he found overwhelmed with grief and despair at having been obliged to leave his wife and family in extreme destitution. Meanwhile he had laid the foundation of what eventually grew into the great and influential congregation of Priests of the Missions; an association of priests who devote themselves to the work of assisting the parochial clergy by preaching and hearing confessions periodically in those districts to which they may be invited by the local pastors.

The rules of this congregation were finally approved by Urban VIII. in 1632; and in the following year the Fathers established themselves in the so-called Priory of St. Lazare, in Paris, whence their name of *Lazarists* is derived. From this date, his life was devoted to the organization of works of charity and benevolence. To him Paris owes the establishment of the Foundling Hospital, and the first systematic efforts for the preservation of the lives, and the due education of a class theretofore neglected, or left to the operation of chance charity. The pious Sisterhood of Charity is an emanation of the same spirit, and Vincent was intrusted by St. Francis of Sales with the direction of the newly-founded order of Sisters of the Visitation. The queen, Anne of Austria, warmly rewarded his exertions, and Louis XIII. chose him as his spiritual assistant in his last illness. He was placed by the queen-regent at the head of the *Conseil de Conscience*, the council chiefly charged with the direction of the crown in ecclesiastical affairs; and the period of his presidency was long looked back to as the golden era of impartial and honest distribution of ecclesiastical patronage in France. Vincent was not, in any sense of the word, a scholar, but his preaching, which (like that of the Fathers of his congregation of Lazarists) was of the most simple kind, was singularly affecting and impressive. He left nothing behind him but the *Rules or Constitutions of the Congregation of the Mission*, 1658; *Conferences on these Constitutions*, 4to; and a considerable number of letters, chiefly addressed to the priests of the mission, or to other friends, on spiritual subjects. He died at the advanced age of 85, at St. Lazare, September 27, 1660, and was canonized by Clement XII. in 1737. His festival is held on the 19th July, the day of his canonization.

PAUL (PETROWITSCH), Emperor of Russia, the second son of the unfortunate Peter III. and the Empress Catharine II., was born in 1754, became heir-apparent on the death of his elder brother in 1763, and succeeded his mother on the imperial throne in 1796. The tragical death of his father when he was still a child, and the neglect and want of confidence with which his mother treated him, exerted a baneful influence on the character of P., who was kept in compulsory seclusion while Catharine shared the administration of the government with her favorites. In 1776, P., on the death of his first wife, a princess of Hesse-Darmstadt, married the Princess Dorothea of Württemberg, by whom he had four sons—the late Emperors Alexander and Nicholas, and the Grand Dukes Constantine and Michael, and several daughters. After spending some years in traveling with his wife through Germany, France, and Italy, P. was recalled by his mother, who assigned to him the palace of Gatchina, 30 miles from St. Petersburg, as his settled residence, while she took his children under her own immediate care. The death of the empress in 1796 released him from his unnatural restraint, and he ascended the throne with no practical acquaintance with the mechanism of government, and no knowledge of the people whom he was called to rule over. A determination to change everything that had existed under the previous reign, and to wreak vengeance on the murderers of his father, were the predominating influences that guided his actions; and his earliest measures, which were the disgrace of his father's murderers, and the pardon of all Polish prisoners, gave hopes of a good reign; but the capricious violence of character and incapacity for business which P. betrayed, soon disappointed the hopes that he had awakened. No department of the state was free from his frivolous interference, and no class of the nation exempt from the effect of his arbitrary legislation. While he irritated the soldiery by vexatious regulations in regard to their dress, he offended the nobles by imperious enactments as to the ceremonials to be observed in his presence. His foreign policy was marked with similar caprice.

After having adopted a system of neutrality in the war between France and the rest of Europe, he suddenly declared in favor of the allied powers, and sent an army of 56,000 men under Suwaroff into Italy. The success of his general encouraged him to send a second army of equal strength to co-operate with the Austrians; but their defeat in 1799 induced P. to recall Suwaroff with the Russian troops; and having retired from the allied coalition without having given any reason for his conduct, he quarrelled with England, because she would not comply with his whimsical demand for the surrender of Malta, and his own recognition as Grand Master of the Order of Malta, and entered into a close alliance with Bonaparte, who was then First Consul. The jealousy and

hatred of England by which both were actuated, proved a powerful bond of union between them; and in furtherance of their scheme of uniting all the smaller maritime powers into one vast confederation against England, P. concluded a convention with Sweden and Denmark for the purpose of opposing the right insisted on by England of searching neutral vessels. The result was that the English government sent a fleet into the Baltic under Nelson to dissolve the coalition, at the close of March 1801. P. was preparing to give material aid to the Danes, when a conspiracy was formed at St. Petersburg to put a stop to the capricious despotism under which all classes of men in Russia were groaning. The conspirators, whose numbers included Count Fahlen, the most influential man at court, General Beningsen, Uwarow, and many other distinguished nobles and officers, appear originally to have intended only to force P. to abdicate, but his obstinate disposition led to a scuffle, in which the emperor was strangled, March 24, 1801.

PAULDING, JAMES KIRKE, an American author, was born at Pleasant Valley, New York, August 22, 1779. His father was a farmer, descended from the early Dutch settlers. Self-educated, and early developing a tendency to literature, he was a friend of Washington Irving, and wrote a portion of *Salmagundi*. During the war of 1812, he published the *Diverting History of John Bull and Brother Jonathan*; in 1813, a parody of the *Lay of the Last Minstrel*, entitled *A Lay of the Scotch Fiddle*; and in 1814, a more serious work, *The United States and England*, a defence against articles in the *Quarterly Review*. This work attracted to him the attention of President Madison, and caused him to be appointed a member of the Board of Naval Commissioners. In 1817, he published a defence of the southern states and of slavery in *Letters from the South, by a Northern Man*; in 1819, a new series of *Salmagundi*; in 1822, *A Sketch of Old England, by a New England Man*; and in 1824, *John Bull in America or the New Munchausen*, a satire on the writings of certain British tourists. This was followed by *Königsmarke*, a novel (1825); *Merry Tales of the Three Wise Men of Gotham* (1826); *The New Pilgrim's Progress* (1828); *Tales of a Good Woman* (1829); *Book of St. Nicholas* (1830). These works, mostly humorous and satirical, had various degrees of local popularity; but in 1831 he produced *The Dutchman's Fireside*, a novel that was reprinted in England, and translated into French and Dutch; and in 1832, *Westward Ho!* which attained to a similar popularity. These were followed by a *Life of Washington* (1835), *Slavery in the United States* (1836), in which the institution is defended on social, economical, and physiological grounds. He held at this period the lucrative post of Navy Agent at New York, and was by Mr. Van Buren appointed Secretary of the Navy, which gave him the position of cabinet minister. At the close of Mr. Van Buren's presidency in 1841, Mr. P. retired to a country residence at Hyde Park, New York, where he wrote *The Old Continental*, a novel (1846); *The Puritan and his Daughter* (1849); and with his son a volume of Plays and Fairy Tales. He died at Hyde Park, New York State, April 6, 1860.

PAULICIANS, an ancient sect of the Eastern Empire, who, by Catholic writers, are reckoned an offshoot of the Manichæans (q. v.). According to Peter of Sicily and Photius, the sect originated in Armenia from two brothers named Paul (from whom it is alleged to have received its name) and John, who flourished in the 4th century. Others trace it to an Armenian named Paul, who lived under Justinian II. The P. were at all times treated with much suspicion, and repressed with great severity, by the eastern emperors; Constans, Justinian II., and Leo the Isaurian especially labored to repress them, and, indeed, with the exception of Nicephorus Logotheta (802–811), it may be said that all the emperors, with more or less rigor, persecuted them. Their greatest enemy, however, was Theodora (841–855), who, having ordered that they should be compelled to return to the Greek Church, had all the recusants cruelly put to the sword or driven into exile. A bloody resistance, and finally an emigration into the Saracen territory, was the consequence; and it is from the Paulician settlers in Bulgaria (Catholic historians) that the Manichæan doctrines which tinged the opinions of most of the medieval sects, are supposed by Roman Catholic historians to have found their way into the eastern provinces of the Western Empire. Even so late as the 17th c., according to Mosheim (ii. 238), there was a remnant of this sect existing in Bulgaria.

It is proper, however, to notice that a very different view of the character and doctrines of the P. has been advocated by such modern writers on ecclesiastical history as Gieseler and Neander, according to whom they had their origin from one Constantine of Mannanalis (near Samosata), an Armenian, who had received a present of two volumes—one containing the four gospels, and the other the epistles of Paul—and who afterwards assumed the name of Paul, in testimony of his great veneration for that apostle. The distinctive characters of his doctrine and that of his followers were the rejection of the worship of the Virgin, the saints and the cross, the denial of the material presence of Christ in the Eucha-

rist, and the assertion of a right freely to search the Scriptures; and the charge of Manichæism was falsely brought against them by their persecutors.

PAULLI'NIA. See GUARANA BREAD.

PAUL'S (St.) CATHEDRAL in London is noted from its being the largest and most magnificent Protestant church in the world, and second only to St. Peter's in Rome among the religious structures of modern times. The site of the present building was occupied about 610 by a Christian church dedicated to St. Paul. This church continued till 1083, when it was destroyed by fire. From its ruins arose a much more splendid edifice—the immediate precursor of the present cathedral. In 1137, the building suffered severely from fire; but, that being the great age for splendid churches, it was soon restored with great magnificence, the bishops and the people contributing most liberally to defray the cost. Old St. Paul's was the largest church in the country, being 690 feet in length, 130 in breadth, and about 150 feet high. The total height of the stone tower and the spire, covered with lead, which surmounted it, was 520 feet. The cloister was 90 feet square, with a beautiful chapter-house in the center. In 1666, the great fire of London completely destroyed the old cathedral, along with a large portion of the city and most of the churches; and thereafter, Sir Christopher Wren was employed to design about 50 of the new churches, and, among others, the new cathedral.

In 1673, he submitted several designs for a new cathedral to the king, who selected one, and ordered a model of it on a large scale to be prepared. This was done by Wren, and the model still exists. Its plan is in the form of a Greek cross, having a large dome over the center, supported on eight arches. This was, however, eventually departed from; and the new design was modelled on that of a Gothic cathedral, with an interior length of 460 feet, width 240 feet across transepts, and a nave 94 feet wide. The dome, and the eight supporting arches of the model, are preserved; but in the new design the angle arches lead to no spacious compartment, but to small dark passages only; while the upper portions of these great arches are blocked up with other arches, introduced for constructive purposes, but very destructive of the architectural effect. The plan of supporting the dome on eight arches had the charm of novelty, and also of simplicity of construction, but it made the arches themselves too small in proportion to the great span of the dome. The constructive skill displayed by Wren in this building is universally acknowledged and admired, but it is thought that he has allowed the mechanical exigencies of the work to interfere too much with its decorative requirements. The dome, for example, is constructed on a new and most masterly principle, the thrust of the vault being counterbalanced by the weight of a brick cone, which is carried up to support the stone lantern over the exterior dome. But in order to carry this out with the least expenditure possible, the drum, or plain cylindrical wall under the dome, is sloped inwards, so that the columns with which it is decorated appear to the spectator below to be falling inwards, thus producing a painful and disagreeable effect. Great exception is taken to the fact, that the external dome is of wood, and not of stone, and so liable to premature decay; but the same may be said of the wooden roofs over the vaults of Gothic cathedrals; and by making it of wood, Sir Christopher was enabled to raise it to a height which makes it one of the noblest buildings of the kind in the world.

The design of the nave, from the classic vaulting with which it is covered, is necessarily to a great extent a failure. When domes, or intersecting vaults, are used in a classic building, the compartments must be about square; there can therefore be but a small number of nave piers, as compared with those of a Gothic cathedral, and the perspective effect of the latter is thus entirely wanting. The same is the case at St. Peter's. The dome is particularly successful, and is admitted to be the finest in existence; no other being so graceful and varied in outline and yet so massive in general effect. Its height from the pavement to the top of the cross is 404 feet. The west front, as seen from Ludgate Hill, is most striking; the two campaniles group most harmoniously with the dome, and, together with the portico, produce a most pleasing and remarkable effect. This front must, however, be condemned, along with the screen-walls, if strictly criticised. The upper portico appears to indicate an upper story where there is none, and the actual construction and true form of the building are not expressed at all. St. Paul's is the burial-place of many heroes and men of distinction, whose tombs are in the crypt, and whose monuments adorn the interior of the cathedral. Amongst these are Nelson and Wellington, Collingwood, Abercromby, Moore, Howe, St. Vincent, Picton, Rodney, and many other celebrated soldiers and sailors; Howard, Johnson, Reynolds, Barry, Opie, West, Astley Cooper, Sir William Jones, Sir Christopher Wren, and other distinguished civilians. Several of the monuments are by Flaxman, Chantrey, Bacon, and Rossi; but it

must be confessed that they savor generally too much of heathen mythology, to be appropriate in a Christian cathedral.

PAULUS ÆGINE'TA, a celebrated Greek physician, was born in the island of Ægina, and flourished during the conquests of the Calif Omar in the 7th century. Of his life we know almost nothing more than that he pursued his medical studies first at Alexandria, and afterwards in Greece and other countries. His forte lay in surgery and obstetrics, in the latter of which departments of medicine his practice was great. He abridged the works of Galen, and was deeply read in those of Ætius and Oribasius, while he always exercised an independent judgment in forming his conclusions. His description of diseases are brief and succinct, and also complete and exact. He often grounds his explanation of morbid phenomena on Galen's theory of the cardinal humors; while in surgery his writings abound with novel and ingenious views. His works—the principal of which is commonly called *De Re Medica Libri Septem* (Lond. 1834)—have passed through many editions, of which the best is that completed at Lyon in 1567, and they have also had many translators, of whom the best in English is Dr. Francis Adams.

PAULUS DIACONUS (also called PAULUS LEVITA, both surnames being derived from his ecclesiastical office), one of the most learned men of his time, and the greatest Lombard historian, was born of a noble Lombard family at Friuli about 730. His father's name was Warnefrid. He received a superior education at Pavia, at the court of the Lombard king Ratchis, and appears to have continued at court during the reigns of his successors, Aistulf and Desiderius, and to have accompanied Adelperga, the daughter of Desiderius, whose education he had conducted, to the court of her husband, Duke Arichis of Beneventum. For her he wrote, in 781, after he had, become an ecclesiastic, one of his principal works, his *Historia Romana*, a work of no authority, as it is a mere compilation from works which we possess, but which was greatly used during the whole of the middle ages, as the many manuscripts, recensions, and continuations of it, attest. An edition of the genuine text is still awaiting, but a great part of it is given in Muratori's *Rerum Italicarum Scriptores*, vol. 1 (Milan, 1738).

In 781, P. became a monk of Monte Casino; but afterwards went to France, and won the esteem of Charlemagne in a high degree by his character and learning. He aided that monarch in his schemes for the promotion of learning, and introduced the study of the Greek language into France. He made a collection of homilies from the best sources, at the emperor's desire, known as the *Homiliarium*, often printed between 1482 and 1569, and translated into German and Spanish. At the request of Angilram, Bishop of Metz, he also wrote a history of the Bishops of Metz, *Gesta Episcoporum Mettensium* (printed in Pertz's *Monumenta Germaniæ Historica*, vol. 2), the first work of the kind on the north of the Alps, but the example of which was soon very generally followed. In 787, he returned to his convent, where he remained till his death, which is said to have taken place in 797. In the latter years of his life, he wrote his History of Longobards (*De Gestis Langobardum*, Libri 6), but did not live to complete it, bringing down the history only to the death of Liutprand in 744. There are several editions of this work, the best of which is contained in the work of Muratori. It is characterized by remarkable candor, and a style unusually pure for that age. The high repute in which this work also was long held, is attested by the great number of manuscripts and continuations. P. was likewise the author of a number of theological works, and of some hymns and letters still extant.

PAULUS, HEINRICH EBERHARD GOTTLOB, a German theologian of great note in his day, and one of the leaders of the Rationalists at the close of the last and the first quarter of the present century, was born at Leonberg, near Stuttgart, 1st September 1761. He gave himself to the study of oriental languages at Göttingen, and afterwards prosecuted it in London and Paris. In 1789, he was called to the professorship of Oriental Languages at Jena, and in 1793 became Professor of Geology, on the death of Döderlein. Here he especially signalized himself by the critical elucidation of the Scriptures of the Old and New Testament, in so far as they presented oriental characteristics. The result of his labors may be seen in his *Philologisch-kritischen und historischen Commentar über das Neue Testament* (4 vols. Lüb. 1800—1804); *Clavis über die Psalmen* (Jena, 1791); *Clavis über den Jesajas*, and other writings belonging to this period of his literary activity. In 1803, he removed to Würzburg; in 1808, to Bamberg; in 1809, to Nürnberg; and in 1811, to Ansbach. During these various changes, he had ceased to be a professor, and become a director of ecclesiastical and educational affairs; but in 1811 he accepted the professorship of Exegesis and Ecclesiastical History at Heidelberg. In 1819, he started a kind of historico-political journal entitled *Sophronizon*, in which he continued to write for about ten years. His contributions were marked by weighty sense, modera-

tion, and knowledge of his various subjects, and won him great applause at the time.

As a theologian, he is generally looked upon as the type of pure unmitigated rationalism—a man who sat down to examine the Bible with the profound conviction that everything in it represented as supernatural was only natural or fabulous, and that true criticism consisted in endeavoring to prove this. From his numerous writings we select for mention the following: *Memorabilien* (Leip. 1791—1796); *Sammlung der merkwürdigsten Reisen in den Orient* (7 vols. Jena, 1792—1803); *Leben Jesu, als Grundlage einer reinen Geschichte des Urchristenthums* (2 vols. Heidelb. 1828); *Aufklärende Beiträge zur Dogmen-Kirchen- und Religionsgeschichte* (Bremen, 1830); and *Exegetisches Handbuch über die drei ersten Evangelien* (3 vols. Heidelb. 1830—1833.) P. died 10th August, 1851, at the advanced age of 90—having lived long enough to see his own rationalistic theory of Scripture give place to the 'mythical' theory of Strauss, and that in its turn to be shaken to its foundations partly by the efforts of the Tübingen school, and partly by those of Neander and the 'Broad Church' divines of Germany. See P.'s *Skizzen aus meiner Bildungs- und Lebensgeschichte zum Andenken an mein 50-jähriges Jubiläum* (Heidelb. 1839), and Reichlin Meldegg's *H. E., G. Paulus und Seine Zeit* (2 vols. Stuttg. 1853).

PAUPER COLONIES are establishments at Frederiksoord and Veenhuizen in the Netherlands province of Drenthe, and at Willemsoord and Ommerschans in Overijssel. They were erected by a benevolent society to employ poor people in cultivating land and various industries. In 1858, the society suspended payments, and the state took the temporary management, arranged with the creditors, and finally retained Ommerschans and Veenhuizen, leaving Frederiksoord and Willemsoord to be managed by the society.

January 1, 1875, the government colonies contained 2809 persons. There were 2223 men and 507 women; 54 boys and 36 girls under 16 years. Protestants, 1948; Roman Catholics, 894; Jews, 38. Could read and write, 2071; able for work, 2657. They have all been convicted, by a magistrate, of begging; and are employed in agriculture and various handicrafts. Peat is largely prepared; coffee-bags and other coarse fabrics are manufactured. Rye, oats, buckwheat, potatoes, &c., cover 2000 acres, and 1200 are in grass. These institutions are a great expense to the nation, but have reduced the numbers and improved the social condition of destitute people.

The colonies of the benevolent society extend to about 6000 acres, and the inhabitants are either tenant cotters, with about 7 acres of land to each house, or labor for the company. The cotter families pay for a house and land a yearly rent of £4, 8s. 4d.; the use of a cow being also obtained for a small hire. The factory-workers weave sacking, coarse cottons and linens, make baskets, mats, straw-hats, &c. There are two Protestant churches, a Roman Catholic chapel, and a synagogue. These colonies have not been self-supporting, and are partly maintained by the annual contributions of 5070 members, gifts, legacies, &c. January 1, 1875, pop. 1956. Land produce, hay, rye, oats, buckwheat, potatoes, oak wood and bark, &c. Stock—303 cows and oxen, 34 calves, 27 horses, 251 sheep, and 40 swine. In 1874, 1028 acres were cultivated. The property, stock, &c. of the society are valued at £78,615, and the debts at £12,300. The position of the colonists has been greatly improved, and their homes show signs of industry and comfort. When working in the factories, a tenth part of their earnings is placed in a reserve fund to be paid to them in winter or in time of sickness.

PAUSA'NIAS, a famous Spartan regent and general, the son of Cleombrotus, and nephew of Leonidas. He commanded the confederate Greeks in the important battle of Plataea (479 B.C.), in which the Persians were totally routed, and their leader, Mardonius, slain. He then marched his troops against Thebes, and compelled the inhabitants to give up the chiefs of the Persian party to him for punishment. Elated by this victory, however, he became in an extreme degree haughty and vain-glorious, took all the credit to himself, and allowed none to the Athenian generals, Aristides and Kimon, who commanded under him, and treated all the other Greeks as if the Spartans were their lords. Nevertheless, he still continued his conquests, capturing Cyprus and Byzantium. It was here he first began to play false to Greece. He entered into secret negotiations with Xerxes, with the view of becoming ruler, under the Persian monarch, of the whole country, and in his journey through Thrace, even adopted the dress and luxurious habits of a Persian satrap, and surrounded himself with a body-guard of Persians and Egyptians. Being recalled, on account of these things, by the Spartans, his former services procured his acquittal. He then returned to Byzantium, where he renewed his traitorous intrigues, was expelled from the city for a criminal assault upon a Byzantine lady, withdrew to the Troad, and there continued his treachery. He was a second time called to account by the Spartan ephors, but again escaped,

though with greater difficulty. Yet his passion for the sovereignty of Greece, even though at the expense of the national liberties, once more drove him to play the traitor. He tried to stir up the Helots, but was taken in his own net. A Helot betrayed him. When P. found his position desperate, he took refuge in a temple of Athene. Hereupon the people blocked up the gate of the temple with heaps of stones, and left him to die of hunger, his own mother depositing the first stone.

PAUSANIAS, one of the most eminent of Greek geographers and historians, was probably a native of Lydia in Asia Minor, and was born some time in the 2d century. He traveled through almost all Greece, Macedonia, and Italy, and also through part of Asia and Africa, and composed from his observations and researches an Itinerary, entitled *Hellados Periegesis*, in ten books, describing the different parts of Greece, and giving a particular account of the monuments of art and of the legends connected with them. His style is by no means pure; but in matters of his own observation he is most trustworthy, and his work is, on many subjects, one of the most valuable sources of information that we possess. There are numerous editions of his work; the oldest was printed at Venice in 1516 by Aldus; and the most recent is that by J. H. C. Schubart and C. Walz (3 vols. Leipz. 1838—1840). Translations of P. exist in English, German, and French.

PA'VEMENT, flat stones or 'flags' used for the flooring of halls, kitchens, and other apartments, and frequently for foot-paths; also the stone covering of the roadway of streets. The stones used for flags vary in different districts, according to the geological formation of the neighborhood. The pavements now most commonly used in England and Scotland are the Arbroath and Caithness stones—the former a softer and more agreeable stone than the latter, which is exceedingly hard and slippery when wet. Pavement should be carefully laid on a solid dry foundation, and set in a good bed of concrete or lime, and the joints pointed with cement. It may also be laid on small dwarf walls, built of brick, so as to support all the edges—this is a good method for keeping the floor dry.

THE PAVING OF STREETS is of early date, and is, in fact, necessary to any considerable degree of civilization and traffic. The Romans paved their streets in the same elaborate and solid manner in which they paved their highways. See ROADS. Portions of the ancient pavement of the streets of Rome are in use to the present day, and the pavement of Pompeii remains entire. It is laid with large blocks of stone of polygonal shape (like Cyclopean masonry), very carefully fitted together, and of considerable depth, and below there is a carefully prepared basis, often composed of several distinct strata. Some of the Italian towns—Florence, for instance—have still pavement of this description, and no foot-pavement.

The medieval cities were almost all unpaved till about the 12th c., when the main streets of the chief towns began to be protected with stone. The plan now adopted is nearly the same in all the cities of Europe. The first thing to be done is to secure or make a solid foundation. This is done, where the natural substratum is not of a solid kind, by laying the street with a solid bed of concrete, having a slope from the middle to the sides to throw off the water. On the concrete is placed the real pavement, which is composed of blocks of granite, trap, or other tough rock. These should be rectangular, and the deeper the better. They are generally about 10 inches to 12 inches in depth, and 6 inches or 7 inches broad, and from 1 to 2 feet in length. They should be all bedded and jointed in strong mortar. This is not often done, as it is thought sufficient to bed the stones in sand and grout them with hot lime on the top. It is clear, however, that the more equal the stones are in depth, and the more solidly they are bedded, the longer they will last. Other materials besides stone have been tried for the paving of streets—such as blocks of wood with the end up, and blocks of cast iron. The wooden pavement is delightfully easy, and not noisy, but in wet weather it is exceedingly slippery. Cast-iron is too hard, and causes too much jolting and noise.

The great obstacle in the way of really good pavement in modern streets is the necessity of frequently breaking it up for the laying and repairing of pipes for gas, water, &c. The true remedy—and, in the end, the cheapest—would be to have, in the chief streets at least, sub-ways or tunnels for drains and pipes, accessible without breaking up the pavement.

PAVI'A, a city of Northern Italy, capital of the province of the same name, on the left bank of the Ticino, 20 miles south of Milan, and 7 miles above the confluence of the Ticino and the Po. A covered bridge of eight arches connects the city with the suburb of *Borgo Ticino*, on the right bank of the river, and from this bridge the *Strada Nuova*, or *Corso*, the principal thoroughfare, leads north, and extends to the outskirts. The city is large, surrounded by walls, and has an imposing appearance, bearing the impress of antiquity. In former times, it was called the 'city of

a hundred towers; but the palace of Theodoric, and the tower where Boëthius wrote the treatise *De Consolatione Philosophiæ*, no longer exist; among the remaining ones are those of Belcredi and Del Maino, which are each 169 feet high. Its oldest church, and perhaps the oldest in Italy, is that of San Michele, which, although the date of its foundation is uncertain, is first mentioned in 661. The cathedral, containing some good paintings, was commenced in 1484, but was never finished. In a beautiful chapel attached to it, are the ashes of St. Augustine, in a sarcophagus ornamented with 50 bassi-rilievi, 95 statues, and numerous grotesques. In the Church of San Pietro in Ciel d'Auro are deposited the remains of the unfortunate Boëthius. The Certosa of P., the most splendid monastery in the world, lies four miles north of the city. It was founded in 1396, contains many beautiful paintings, and abounds in the richest ornamentations. It has an octagonal cupola, painted ultramarine, and enameled in gold. It was sacked by the French in 1796. Its church is in the form of a Latin cross, and is 249 feet long, and 175 feet wide.

The university of P. is said to have been founded by Charlemagne in 774, and was one of the most famous seats of learning during the middle ages. Its efficiency was much increased by Galeazzo Visconti, who bestowed many privileges upon it in the year 1396. It consists of numerous colleges, and attached to it are a library of 120,000 vols., a numismatic collection, anatomical, natural history, and other museums, a botanic garden, a school of the fine arts, &c. The university is attended by about 700 students. It has numbered among its professors Aiciati, Fidele, Spallanzani, Volta, Scarpa, Foscolo, and Monti. The other chief edifices comprise private palaces, theater, gymnasium, &c. P. carries on a good trade in wine, rice, silk, and cheese. Pop. (1881) 29,836.

P., the ancient *Ticinum* (afterwards *Papia*, whence the modern name), was founded by the Liguri; it was sacked by Brennus and by Hannibal, burned by the Huns, conquered by the Romans, and became a place of considerable importance, at the end of the Roman empire. Then it came into the possession of the Goths and Lombards, and the kings of the latter made it the capital of the kingdom of Italy. It became independent in the 12th c., then, weakened by civil wars, it was conquered by Matthew Visconti in 1345. Since that period, its history is merged in that of the conquerors of Lombardy. Here, in 1525, the French were defeated by the imperialists, and Francis I. (q. v.) taken prisoner; but in 1527, and again in the following year, it was taken and laid waste by the French. It was stormed and pillaged by Napoleon in 1796, and came into the possession of Austria by the peace of 1814. Since 1859, it has been included within the kingdom of Italy.—The province of P. has an area of 1290 sq. m.; pop. (1872) 448,435.

PAVIA. See HORSE-CHESTNUT.

PAVILION, a portion of a building, under one roof, of a tent-like form, with the slope of the roof either straight or curved. This form is much used in France—the higher parts of the new buildings at the Louvre are good examples of pavilions. Pavilion roofs are sometimes called French roofs.

PAVLOGRA'D, a town of South Russia, in the government of Ekaterinoslav, and 88 miles east-north-east of the town of that name, on the Voltcha, an affluent of the Dnieper. It was founded in 1780, during the reign of the Empress Catharine II., and its first colonists were the Zaporogsky Cossacks. But in 1782, a great portion of the English garrison of Fort Magon in Minorca, having been subdued by the Spaniards, and being forced by the terms of their capitulation to renounce the English service, obtained liberty from the Empress Catharine to settle in Pavlograd. The garrison was composed chiefly of Corsicans. Pop. of the town (1880) 11,500.

PAVO'NIDE, a name sometimes used to designate the family of gallinaceous birds more commonly called *Phasianide* (q. v.), sometimes applied as a designation to a portion of that family separated from the rest on very slight grounds, the chief distinction being the greater expansion of the tail. See PEACOCK and POLYPLECTRON.

PAWL, on shipboard, is a catch or hook to prevent the capstan from flying round backwards during a pause in the heaving. A similar catch is used in the common windlass.

PA'WNBROKING (Du. *pand*, Ger. *pfand*, Fr. *pan*, a pledge). The business of lending money on pawns or pledges appears to have been carried on in England by certain Italian merchants or bankers as early at least as the reign of Richard I. By the 12th of Edward I., a message was confirmed to these traders where Lombard Street now exists; the name being, according to Stow, derived from the Longobards who used to congregate there for business purposes. Subsequently, these merchant adventurers became known generally by the name of Lombardens. Their wealth became proverbial. Among the richest of them were the celebrated family of the Medici; from whose armorial bearings it

is conjectured that the pawnbroking insignia of the three balls have been derived. The bankers of Lombard Street appear to have exercised a monopoly in pawnbroking until the reign of Elizabeth. The trade is first recognized in law by the act 1st James I. c. 21. In the perilous days of Charles I. the goldsmiths were very frequently chosen as the custodiers of plate and money; which circumstance seems to have suggested to them the profitable business of lending on pawns and discounting bills. From this time, the oppression and extortion often exercised by brokers has continued to attract much public attention and discussion; and an effort has been made, both in England and on the continent, to obviate the evil by the establishment of what are called *Monts de Piété*, the object of which is to advance small sums to the very poor at a moderate interest. See MONT DE PIÉTÉ. In England, after many abortive efforts, a *Mont de Piété* office was started in 1708; but in 1731 it came to a disastrous end. The bubble mania of 1824—1825 gave rise to a similar scheme. In this instance upwards of £400,000 was subscribed; but the undertaking miscarried, and the capital was lost. A similar fate attended the Irish *Monts de Piété*, of which there were eight in 1841. In 1848, they had all disappeared except one, which lingered to 1853; when it also expired. It would thus seem hopeless to attempt to establish a pawnbroking office in England on any other footing than an ordinary commercial one. The cause of failure will be found to lie, generally, in the great difficulty of conducting a commercial undertaking on charitable principles, with sufficient energy and ability to compete successfully with others originating in the ordinary motives which lead men to engage in trade.

It hardly admits of dispute that the pawn-shop, in its practical working, is an evil—necessary, it may be, but still an evil; and the having recourse to it is strongly to be discouraged. There are, doubtless, cases where men are driven to pawn their goods from causes which are not discreditable, and which do not render it certain that they are on the road to ruin; but such cases are rare exceptions to the general rule. Besides making borrowing too easy, and thus encouraging the fatal habit of anticipating income, the pawn-shop is, in nine cases out of ten, the door to the drinking-shop. Even where the one does not directly lead to the other, it generally does so in the end. That 'borrowing dulls the edge of husbandry' applies with a force increasing in a geometrical ratio as we descend in the scale of society. Admitting, however, that with all its tendency to demoralize, pawnbroking is, in many cases, of value in tiding over unforeseen pecuniary difficulties, it is sufficient to say, that so long as improvidence prevails among large classes of society, and so long as even the most prudent are liable to unforeseen accidents, the accommodation of the pawn-shop is to a certain extent a necessity, and like other demands of the public will continue to be supplied. Nor are those who supply this demand to blame, any more than the caterers for many other expenses which economists pronounce to be wasteful. The fault, where there is a fault, is in those who borrow, not in those who lend. The legislature, accordingly, instead of trying to put down pawnbroking, has wisely confined itself to putting it under stringent regulations so as to prevent as far as possible its abuse.

Pawnbrokers are restricted in their business as regards loans under £10, by the statute 35 and 36 Vict. c. 93, which repealed all the prior statutes, and defined new offences, and it also extends to 'leaving-shops.' The statute requires them to take out a license (for which they pay £7, 10s.), and keep exhibited outside their names and business, fixes the rate of interest, and makes it necessary that a table of interest should be put up in a conspicuous part of the shop, to keep books with correct entries of the name and place of abode of the owners of goods, &c. If the owner of goods has just cause to suspect that such goods have been pawned at a particular shop, the justices of the peace may grant a search-warrant, and if found, the goods may be restored to the owner. Pawnbrokers are expressly prohibited from taking in pledge linen, apparel, or unfinished goods, intrusted to any person to wash, manufacture, make up, &c., and also any goods under circumstances which should have aroused their suspicions. Goods which have been in pledge for a year may be sold, and the pawnbroker may bid for them, if done openly. If the duplicate is lost, the owner of the goods may obtain a fresh one on verifying the fact of his being the owner before a justice of the peace. If the money borrowed be tendered with interest within the year, the pawnbroker is bound to deliver them up, otherwise a justice of the peace may by order compel him to do so. The mode of selling forfeited goods is prescribed by the statute, for all pledges above ten shillings, to be by auction—the catalogues to contain the names of the pawnbrokers, and the month when the goods were pawned, and the number entered in the pawnbroker's books. The result of the sales is to be entered in the books of the pawnbroker and auctioneer, and the surplus is to be paid on request to the owner of the goods if claimed within 3 years. In the case of pledges below ten shillings, the pawn-

broker becomes the absolute owner after 12 months. Pawnbrokers are not to take goods in pawn from persons under the influence of drink, or under the age of 12.

In case of penalties imposed on pawnbrokers for offences against the act, the complainant, if the party aggrieved, and then only, generally gets half. In case of fire the pawnbroker broker is liable to the owner for the value of the goods (after deducting the amount of loan and profit), and 25 per cent. on the amount of the loan; but this only if the claim be made within 12 months after the pawning.

The greatest pawnbroking establishment in the world is the Mont de Piété of Paris. It trades with borrowed capital, and with the profits of former years temporarily capitalized. Recent statistics are not at hand; but it has been reported to receive in one year 1,481,575 pledges, valued at £1,086,371, including renewals, and the average charge was about 15 per cent. per annum. Taking one of the largest offices in England out of London, we find that in one year it received 142,835 pledges, valued at £36,560, including renewals, and the average charge was 25 per cent. per annum. Various circumstances render the difference between the rates really much less than these figures indicate; still there is no doubt that the interest charged on small loans is lower at the Mont de Piété of Paris, than in the pawnbroking offices in this country; but this convenience is limited by the fact of the French establishment taking no loans under three francs.

What used to be called in England the 'dolly shop,' and in Scotland the 'wee pawn' system was carried on by brokers, ostensibly buying and selling. They received articles as bought; there being a distinct understanding that the seller was to have an opportunity of repurchasing within a limited time, at an understood increase of price. The general understanding was a penny a shilling a week; a month being usually allowed to redeem the article. The 'wee' broker was commonly resorted to because the article was below the regular dealer's class of goods. The 'wee pawn' was happily abolished in Scotland ten or twelve years ago.

PAWTUCKET, a town of Rhode Island, U. S., on both sides of the Pawtucket River, 4 miles north of Providence. A fall of 50 feet on the river, and its proximity to the sea, caused it to be selected by Samuel Slater, in 1790, as the site of the first cotton factory in the United States. It now contains 13 cotton mills, machine shops, and manufactures of yarn, fire-engines, belting, jewelry, &c. There are 18 churches, 3 banks, 2 newspapers, a public library, with extensive steam-boat and railway connections. Pop. (1870) 6619; (1881) 19,030. A part of North Providence was annexed to P. in 1874.

PAX, called also PACIFICALE and OSCULATORIUM (Lat. *osculor*, I kiss), the 'Kiss of Peace,' and also a sacred utensil, employed in some of the solemn services of the Catholic Church in the ceremony of giving the so-called 'kiss of peace' during the mass. The practice of saluting each other—the men, men, and the women, women—during public worship, and particularly in the *agape*, or love-feast, is frequently alluded to by ancient writers, as Cyril of Jerusalem, Catech. xv., and St. Augustine, Sermon 227. All the ancient liturgies, without exception, refer to it as among the rites with which the Eucharist was celebrated; but they differ as to the time and the place in the Eucharistic service in which it is introduced. In the Eastern liturgies it is before, in the Western after the Offertory (q. v.) and in the Roman it immediately precedes the communion. The ceremony commences with the celebrating bishop or priest, who salutes upon the cheek of the deacon; and by him the salute is tendered to the other members, and to the first dignitary of the assistant clergy. Originally the laity also were included, but this has long since been abandoned. It is when the mass is celebrated by a high dignitary that the utensil called the pax is used. The pax is sometimes a crucifix, sometimes a reliquary, sometimes a tablet with a figure sculptured or enamelled upon it. Having been kissed by the celebrant, and by him handed to the deacon, it is carried by the latter to the rest of the clergy. In ordinary cases, the pax is given by merely bowing, and approaching the cheek to the person to whom it is communicated. The pax is omitted in the mass of Maundy-Thursdays (q. v.), to express horror of the treacherous kiss of Judas.

PAXO, one of the Ionian Islands, lies 10 miles south-west of the coast of Albania, and 9 miles south-east of the island of Corfu. It is about 5 miles long, and about 2 miles broad. The capital, or rather the chief village, is Port Gaio (pop. 2000), on the east coast. Olives, almonds, and vines are grown, and the island is famous for its oil. Water is sometimes very scarce. Pop. of the island about 3600.

PAXTON, SIR JOSEPH, English architect and horticulturist, was born at Milton-Bryant, near Woburn, Bedfordshire, in 1803. He was sent to Woburn Free School, but left it at an early age, and obtained employment as a working gardener. He entered the service of the sixth Duke of Devonshire, at Chiswick, and was thence transferred to Chatsworth, where he became the duke's

chief gardener. His abilities as a horticulturist found ample scope in the beautiful gardens of Chatsworth, and are further attested by *Paaton's Magazine of Botany*, of which he was editor, as well as other works on plants and flowers. The experience he obtained in designing capacious glass conservatories at Chatsworth led him to propose a Crystal Palace of glass and iron for the Great Exhibition (q. v.) of 1851. It was the first time these materials had been employed on so extensive a scale, and visitors found an inexhaustible theme of admiration in a fairy palace so novel, beautiful, and magnificent. His design obtained for him great popularity and the honor of knighthood. The Crystal Palace of 1851 was removed from Hyde Park, but became the germ of the nobler and more splendid Palace at Sydenham, the construction of which he superintended; the grounds were also laid out by him. Crystal palaces for exhibitions of artistic and industrial objects have since 1851 been constructed at Dublin, New York, Paris, Manchester, &c. In 1854, P. was returned to parliament on the liberal interest for Coventry, which he represented for about ten years. He was a member of many learned societies in Europe, and his works on horticulture and botany are much esteemed. He died in 1865.

PAYMASTER-GENERAL is an officer of the British ministry, but not of the cabinet, charged with superintending the issue of all moneys voted by parliament. He is virtually the paymaster of the public service, having no control over the sums issued, paying merely on the order of the department concerned; and receives £2000 a year as chancellor of the duchy of Lancaster. He is always either a peer or a member of the House of Commons, and changes with the ministry. Of late years the office has been held in conjunction with that of Vice-president of the Board of Trade. The paymaster-general is assisted by a deputy and a staff of clerks, the annual cost of the whole department amounting to about £25,000. The first notice of this office is in the early part of the reign of Charles II., when the paymaster-general was nothing more than the sole paymaster of the army. The present extensive duties of the office have been added by degrees during the 19th century.

PAYMASTER, MILITARY AND NAVAL.—Military paymasters are either 'Control' or 'Regimental.' Of the latter, who constitute by far the more numerous class, there is one to every brigade of artillery, regiment of cavalry, and battalion of infantry. The paymaster holds no other commission, but the appointment is nearly always conferred upon some person who has previously held a combatant rank in the army. The functions of paymaster comprise issuing and accounting for the pay of officers and men, and having charge generally of all the finances of the corps. In discipline, the paymaster is responsible to the officer commanding the regiment; but in all money matters he looks for orders to the War Office alone. He commences with a pay of 12s. 6d. a day, with the relative rank of captain; and after twenty years' service attains the pay of £1, 2s. 6d. a day and relative rank as major. Regimental paymasters were first appointed during the French war.

Control paymasters have financial charge in the military districts or sub-districts. They form a separate department under the Surveyor-general of the Ordnance, comprising paymasters, deputy paymasters, and assistant paymasters.

THE NAVAL PAYMASTER is for a ship what the military paymaster is for a regiment; but he adds to these duties some of those performed in the army by the quartermaster, commissariat, and military storekeeper, for he has charge of the provisions, clothing, and miscellaneous stores, as well as of mere money. Paymasters are commissioned officers, receiving from 14s. to £1, 13s. a day, and ranking, according to service, with lieutenants, commanders, and captains. Up to the year 1844, paymasters were styled pursers, and were paid by profits they made on certain of the ship's charges. At a still earlier period these pursers had been warrant-officers.

PAYMASTER-SERGEANT, in the army, is a non-commissioned officer, whose duty it is to act as clerk to the paymaster. He ranks with other staff-sergeants, and receives from 1s. 11d. to 2s. 11d. a day, according to his corps, with an increase of 6d. after three years' uninterrupted service as paymaster-sergeant.

PAYNISING, a process for preserving and hardening wood, invented by a Mr. Payne. It consists in placing well-seasoned timber in an air-tight chamber, and then, when, by means of a powerful air-pump, the wood is deprived of its air, a solution of sulphuret of calcium, or of sulphuret of barium is admitted, and readily fills up the empty vessels all through the wood. The air-pump is again used, and the superfluous moisture is drawn out, and a solution of sulphate of iron is injected; this acts chemically upon the sulphuret of barium or of calcium, and forms all through the wood either the insoluble sulphate of barium (heavy spar) or of lime (gypsum). The addition of these mineral materials renders the wood very heavy, but it becomes also very durable, and almost incombustible.

PAZ (LA) DE AYACU'CHO, a town of Bolivia, South America, capital of a dep. of the same name, about 20 miles from the south shore of Lake Titicaca, is situated on the east declivity of the Andes, at an elevation of 12,000 feet above the sea, on both sides of a deep ravine, here crossed by nine bridges. The whole city is subdivided into sections by numerous ravines. The streets are generally irregular and steep; there are some good public buildings, several educational institutions, a noble cathedral, and many other churches. It is the seat of a bishop and a university. La P. is the largest city, and the principal commercial emporium of Bolivia—the exports consisting of gold, bark, and other products of the country; and the imports of manufactured goods, the bulk of which comes through Peru. This city, whose original name was Nuestra Señora de la Paz, was founded in 1548. The name was changed in 1825 to its present form, in honor of the national victory of Ayacucho (q. v.). Pop. at census of 1880, 26,000, the greater part of which is Indian.

PEA (*Pisum*), a genus of plants of the natural order *Leguminosæ*, suborder *Papilionaceæ*, closely allied to the genus *Lathyrus* (q. v.), from which it differs chiefly in the triangular style. Two species, supposed to be natives of the south of Europe and of the East, are very extensively cultivated for their seeds (peas), which are the best of all kinds of pulse; the COMMON PEA or GARDEN PEA (*P. sativum*) in gardens, and the FIELD (*P. arvense*) in fields; both of them climbing annuals, with pinnate leaves, ovate leaflets, and branching tendrils in place of a terminal leaflet; the Garden Pea distinguished by having two or several flowers on each flower-stalk, the flowers either red or white, more generally white, and the seeds subglobular; the Field Pea having one flower on each flower-stalk, the flowers always red, and the seeds angular from crowding and compression in the pod. But it is not improbable that they are truly one species, of which the Garden Pea has, through cultivation, departed furthest from the original type. Peas have been cultivated in the East from time immemorial, although the ancient Greeks and Romans do not seem to have been acquainted with this kind of pulse, the cultivation of which was apparently introduced into Europe very early in the middle ages; and its cultivation extends from warm climates, as India, even to the Arctic regions, the plant being of rapid growth and short life.

The seeds of the Garden Pea are used for culinary purposes both in a green and in a ripe state; also the green succulent pods of some varieties, known as Sugar Peas or Wyker Peas, in which the membrane lining the inside of the pod—parchment-like in most kinds—is much attenuated. Field peas are used both for feeding cattle and for human food. For the latter purpose, peas are often prepared by being *shelled*, or deprived of the membrane which covers them, in a particular kind of mill; they are then sold as *Split Peas*, and are much in use for making *Pea Soup*. They are also ground into meal, which is used in various ways, chiefly for making a kind of pottage and of unleavened bread. In the countries bordering on the Mediterranean, peas are roasted in order to eating.

There are innumerable varieties both of the Field Pea and the Garden Pea, those of the latter being so much the products of horticultural art, that they cannot be preserved without the utmost attention. Some of the kinds of garden peas have long stems, and require for their support stakes of six or eight feet in height; others are of humbler growth; and certain dwarf kinds, preferred as most convenient in many gardens, succeed very well without stakes. The largest kinds are sown in rows about four feet asunder. In Britain, garden peas are sown at different times from February to June, in order to secure a supply of green peas during a considerable part of summer and autumn; and in the southern parts of the island they are also sown in the end of autumn, a very little protection being sufficient for them during the winter. Certain small kinds, of very rapid growth, known as *Early Peas*, are preferred for the first sowing, although less productive than many others. The varieties known as *Mammoth Peas* are remarkable for their size and tenderness in a green state, but shrivel as they ripen.

Branches of trees are generally used for pea-stakes, when they can be obtained, and nothing can be better; but in lieu of them, strings are sometimes stretched between poles along the rows. Field peas are sometimes sown alone, and allowed to support each other, where the soil is not very rich, but are very generally sown with beans, to which they cling.

Chalky and other calcareous soils are particularly suitable for peas, and in other soils a good field crop is seldom obtained unless the land has been well limed, or manured with gypsum. The free use of lime is supposed, however, to be unfavorable to the quality of garden peas intended to be used green.

Peas are cultivated to a considerable extent as a field crop in Britain, but are best adapted to those districts in which the climate is least moist, the seeds being very apt to grow in the pods when moist weather prevails in autumn, by which the crop is injured or destroyed. The most productive kinds, being also in

general the most bulky in straw, are very apt to lodge before the pods are filled, in wet seasons, and particularly on rich land. The crop is, therefore, rather a precarious one.

The haulm or straw of peas is used for feeding cattle; and for its sake, field peas are often reaped before they are quite ripe, great care being taken in stacking the straw to provide for ventilation, so that it may not *heat*. Pea haulm is more nitrogenous and more nutritious than hay.

Land to be sown with field peas should be very *clean*, and in particular free of couch grass; otherwise the best management cannot prevent its becoming more foul whilst bearing the pea crop. The seed ought always to be sown in rows, twelve inches apart, or, in rich soils, eighteen or twenty inches apart. Various means are employed for sowing peas; they are not unfrequently ploughed under each second furrow; but the seed ought not to be buried more than four inches under the surface, and indeed that depth is too great; although many farmers sow their peas deeper than they otherwise would, to place them beyond the reach of wood pigeons. All possible means ought to be used to keep the land free of weeds. In some districts, peas are generally sown broadcast, which renders it impossible to do anything for this purpose. In the harvesting of peas, the sheaves are generally left loose till the haulm is somewhat dry. In drying, it shrinks very much. Broadcast peas are often cut with the scythe, and the harvesting of them is managed much as that of hay.—*Winter Field Peas*, a variety with very small seeds, are much cultivated in France and Germany, being sown in October, enduring the severest frosts without injury, and ripening very early.

Besides being one of our most important agricultural and horticultural crops, peas are largely imported into Britain, the quantity sometimes reaching 120,000 quarters. We receive them from Denmark, Prussia, the Hanse Towns, Holland, Morocco, United States, British North America; and of these, Denmark and our North American colonies send the greater part. As an article of food, if not taken too often or without other food, peas are very valuable, as they contain a large percentage of *casein*, which is a flesh-forming principle.

This principle in the pea has been called *legumin*, but chemists are now generally agreed that it is identical with the casein of cheese. The following is an analysis of one hundred parts of pea meal:

Water	14.1
Casein	23.4
Starch	37.0
Sugar	2.0
Gum	9.0
Fat	2.0
Woody Fibre	10.0
Mineral Matter	2.5

100.0

The unripe peas of the garden varieties are amongst our most esteemed vegetables, and the meal of the white or yellow varieties used in soups is a highly nutritious and agreeable food.

A plant found on some parts of the shores of Britain, as well as of continental Europe and North America, and known as the SEA PEA, has been commonly referred to the genus *Pisum*, and called *P. maritimum*, although botanists now generally refer it to *Lathyrus*. It much resembles the common pea; has large reddish or purple flowers on many-flowered stalks; and its seeds have a disagreeable bitter taste. Its abundance on the sea coast at Orford, in Sussex, is said to have saved many persons from death by famine in 1555.—The other species of *Pisum* are few. But the name *P.* is often given to species of other papilionaceous genera. The SWEET PEA and EVERLASTING PEA are species of *Lathyrus*. The CHICK PEA (q. v.) is a species of *Cicer*.

PEA BEETLE, or PEA CHAFER (*Bruchus pisi*), a coleopterous insect, very destructive to crops of peas in the south of Europe and in North America. It is about a quarter of an inch long, black, variegated with bright brown hairs, and with white spots and dots on the wing-cases. It lays its eggs in the young pods, one for each pea, and the larva eats its way into the pea, and completely hollows it out.

PEABODY, GEORGE, an American merchant whose name deserves to be held in remembrance on account of his munificent philanthropy, was born at Danvers, Massachusetts, February 18, 1795. His parents were poor, and his only education was received at the district school. At the age of 11 he was placed with a grocer, and at 15 in a haberdasher's shop in Newburyport. When 22 years old, he was a partner with Elisha Riggs in Baltimore. In 1827 he first visited England, where he settled permanently ten years later. Withdrawing from the Baltimore firm in 1843, he established himself in London as a merchant and money-broker, and accumulated a large fortune. As one of three commissioners appointed in 1848 by the state of Maryland to ob-

tain the restoration of its credit, he refused all payment, and received a special vote of thanks from the legislature of that state. In 1851 he supplied the sum required to fit up the American Department at the Great Exhibition. In the following year he sent a large donation, afterwards increased to 270,000 dollars, to found an Educational Institute, &c., in his native town of Danvers (which is now called Peabody). He contributed 10,000 dollars to the first Grinnell Arctic Expedition; 1,400,000 dollars to the city of Baltimore for an Institute of Science, Literature, and the Fine Arts; 8,000,000 dollars for the promotion of education, endowment of libraries, &c., in the U. S.

From 1862 to 1868, he gave £350,000 for the benefit of the London poor, and in his will he left £150,000 for the same purpose; half a million in all, which has been employed in building dwellings for the working-classes. He died in London in 1869.

PEACE, ARTICLES OF THE, in English Law, are certain complaints made against a person who threatens another with bodily injury, and the redress given is to bind the threatening party over with sureties to keep the peace. All justices of the peace have, by their commission, authority to cause persons to find sufficient security to keep the peace, and an ancient statute also gives authority. Hence any one who is threatened either in person or property, or in the person of his wife or child, may go before a justice of the peace and complain on his oath of the fact. The justice is to consider if the language used amounted to a threat, and if he is satisfied that it does, he issues his warrant to bring the party before him, who is then heard in explanation, and if it is not satisfactory, he is ordered to find sureties. If he cannot do so, he is committed to prison for a limited time, or until the next quarter-sessions. The party, when he finds sureties, is bound over for a term not exceeding twelve months. If he has entered into recognizances (i. e., given a bond with sureties), and he breaks the peace, he forfeits his recognizance, and the sureties' goods can be seized to pay the amount of the bond.

PEACE, OFFENCES AGAINST THE PUBLIC, are those offences which consist in either actually breaking the peace, or constructively doing so by leading indirectly to a breach. These offences are now usually known under the heads of unlawful assemblies, seditious libels and slanders, riots, affrays, challenges to fight, forcible entry and detainer, and libel and slander. Those who take part in an unlawful assembly commit a misdemeanor against the public safety. All persons assembled to sow sedition, and bring into contempt the constitution, are an unlawful assembly. Thus it was held that an attempt to hold a national convention was illegal, for it was impossible to anticipate with certainty the peaceable result of such a meeting. It is, however, somewhat difficult to define precisely what amounts to an illegal assembly, except by saying that it points to some course inconsistent with the orderly administration of the laws. It is the duty of all individual citizens to resist and oppose any unlawful assembly; but the duty rests primarily with the magistrates of the district, who are indictable for breach of duty in not taking active and immediate steps to put down riots. Thus the mayor of Bristol was indicted for not suppressing the riots at the time of the Reform Bill. The magistrates ought to call at once upon special constables to be sworn in, and if these are insufficient, to call for the aid of the military. Seditious libels are also offences against the peace, as inciting directly to a breach. Such are libels vilifying the Sovereign or the Houses of Parliament, or the courts of justice, or even a foreign sovereign, as in the case of Peltier, who was tried for a libel against the Emperor Napoleon I., the tendency of such libel being to breed misunderstanding between our own sovereign and the foreign sovereign. A riot is the most active form of an offence against the public peace.

To constitute a riot, there must be at least three persons engaged together in pursuance of an illegal purpose. Riots often originate in an attempt to redress summarily some private wrong. On such an occasion, before extreme measures are resorted to, and as a test of the good faith of those who are spectators, instead of parties, and by way of full notice to all concerned, the justices of the peace may read the Riot Act, 1 Geo. I. st. 2, c. 5, which commands all persons to disperse within one hour after a proclamation is read, otherwise they will be guilty of felony. Persons not removing within one hour thereafter may be arrested, and carried before a justice, and committed to prison. It is, however, possible that the justices may make a mistake in thinking that to be an illegal assembly which is not so, for the mere reading of the Riot Act does not alter the character of the assembly, and accordingly if the party arrested prove at the trial that it was no illegal assembly he will be discharged. An affray is also an offence against the public peace, being a public assault, i. e., an assault committed in presence of third parties, for this is apt to lead to further breaches of the peace by others joining in it. Thus prize-fights and duels are affrays, and all present at them are principal offenders, and may be arrested by a constable and bound over to keep the peace, and punished by fine and imprisonment

besides. So challenges to fight, provocations to fight, and forcibly entering into a house, are misdemeanors against the public peace.

PEACH (*Amygdalus Persica*), a tree much cultivated in temperate climates for its fruit; a native of Persia and the north of India; of the same genus with the ALMOND (q. v.), and distinguished by oblongo-lanceolate serrulate leaves; solitary flowers, of a delicate pink color, appearing before the leaves; and the sarcocarp of the drupe succulent and tender, not fibrous as in the almond. This difference in the drupe has been made by some the ground of a generic distinction, but there are intermediate states, so that others have doubted if the P. and almond are even specifically distinct. The NECTARINE differs from the P. only in having a smooth fruit, whilst that of the P. is downy, or velvety, and is a mere variety, probably produced and certainly preserved by cultivation. Both peaches and nectarines are divided into *freestones* and *clingstones*. In the former the flesh of the fruit parts from the stone; in the latter it adheres to it. The Freestone P. is the *Pêche* of the French, the Clingstone P. their *Pavie*; the Freestone Nectarine they call *Pêche lisse*, and the Clingstone Nectarine *Brugnon*. Of all these there are many sub-varieties, the finer ones being perpetuated by budding, which in Britain is generally on plum or almond stocks. There is a remarkable variety of Chinese origin, with the fruit compressed and flattened, and with almost evergreen leaves. The P. is much cultivated in the south of Europe, in many parts of the East, in the warmer temperate parts of North and South America, in Australia, &c., as a standard tree; in general, it is rather a small tree with a full head; in Britain, it is generally trained on walls, and in the northern parts of it on flued walls or in hot-houses, although even in Scotland excellent peaches are ripened on open walls without artificial heat. The Nectarine is rather more tender than the peach.

In the extensive P. orchards of New Jersey, Pennsylvania, Maryland, and other states of North America, which sometimes contain 10,000 or 20,000 trees, the fruit is often of very inferior quality, from want of care in cultivation—the orchards being planted by simply depositing the seed in the ground; and much of the fruit is used for making a spirituous liquor called *Peach Brandy*; much of it is dried in ovens, or in drying-houses furnished with stoves, or, in the more southern states, in the sun, each fruit being divided into two parts, and the stone taken out, and when dried it is sent to market to be used for pies; the refuse of the orchards is used for feeding swine.—The P. is a very pleasant and refreshing fruit, and in a stewed form is useful in slight cases of constipation. The leaves, when fresh, have the smell and taste of bitter almonds; and by bruising them, mixing the pulp with water, and distilling, the *Peach Water* is obtained which is so much esteemed by many for flavoring articles of cookery. They have been employed as a sedative and as a vernifuge. The seeds almost entirely agree in their properties with bitter almonds; the flowers exhale an odor of bitter almonds; and both seeds and flowers are employed in the manufacture of a liqueur called *Persico*.

PEACH-WOOD, or **LIMA-WOOD**, a dye-wood imported from South America, supposed to be the produce of a species of *Cesalpinia*, allied to that which yields the Nicaragua wood. It yields a fine peach color, whence its name, and is now much used in muslin and calico printing and dyeing.

PEA'COCK, or **PEAFOWL** (*pavo*), a genus of gallinaceous birds of the family *Pavonida*, or *Phasianida*, of which only two species are known, natives of the East Indies; birds of large size, and remarkable for magnificence of plumage. The bill is of moderate size, somewhat arched towards the tip; the cheeks

Peacock.

nearly naked; the head crested; the tarsi rather long, and armed with a single spur; the wings short; the upper tail-coverts prolonged far beyond the tail, and forming a splendid train—popularly called the *tail*—which is capable of being erected and spread

out into a great disk, the true tail being at the same time erected to support it. The Common P. (*P. cristatus*) has for crest a kind of aigrette of 24 upright feathers, with slender almost naked shafts and broad tip. The tail consists of 18 brown stiff feathers, and is about six inches long. The train derives much of its beauty from the loose barbs of its feathers, whilst their great number and their unequal length contribute to its gorgeousness, the upper feathers being successively shorter, so that when it is erected into a disk, the eye-like or moon-like spot at the tip of each feather is displayed. The lowest and longest feathers of the train do not terminate in such spots, but in spreading barbs, which encircle the erected disk. The blue of the neck, the green and black of the back and wings; the brown, green, violet, and gold of the tail; the arrangement of the colors, their metallic splendor, and the play of color in changing lights, render the male P. an object of universal admiration—a sentiment in which the bird himself evidently participates to a degree that is very amusing, as he struts about to display himself to advantage, and labors to attract attention, affording a familiar proverbial image of ostentation and pride. When the disk is erected, the P. has the power of rattling the shafts of its feathers against each other in a very peculiar manner, by a strong muscular vibration.

The Peahen is much smaller than the male bird, has no train, and is of dull plumage, mostly brownish, except that the neck is green. As in some other gallinaceous birds, the female has been known, in old age, to assume the plumage of the male. Individuals with white plumage not unfrequently occur, in which even the eye-like spots of the tail are but faintly indicated; and pied peacocks, having the deep blue of the neck and breast contrasted with pure white, are sometimes to be seen. The P. is generally supposed to have been known to the Hebrews in the time of Solomon, but it is not certain that the word commonly translated *peacocks* in the account of Solomon's importations from Tarshish (2d Chron. ix. 21) does not signify *parrots*. It is commonly stated that it first became known to the Greeks on the occasion of Alexander's expedition to India, but Aristophanes mentions it in plays written before Alexander was born. The P. became common among the Greeks and Romans; a sumptuous banquet in the latter days of Roman greatness was scarcely complete without it; and wealth and folly went to the excess of providing dishes of peacocks' tongues and peacocks' brains. Throughout the middle ages, also, a P. was often presented at the tables of the great, on great occasions, the skin with the plumage being placed around the bird after it was cooked. The P. is now common in most parts of the world; generally kept, however, except in warm countries, for ornament rather than for profit, although both the flesh and the eggs are very good. It readily partakes of all the ordinary food provided for the poultry-yard, and is fond of buds and succulent vegetables. It is hardly enough even in cold climates, except that few eggs are laid, and the young are difficult to rear, but the adult birds sit on trees or on the tops of houses, stacks, &c., during the keenest frosty nights, never, if they can avoid it, submitting to the confinement of a roosting-place, like that of the common fowl.

Peacocks are found in almost all parts of India, Siam, &c., and the multitudes in which they occur in some districts are wonderful. 'About the passes in the Jungletary district,' Colonel Williamson says, in his *Oriental Field Sports*, 'whole woods were covered with their beautiful plumage, to which a rising sun imparted additional brilliancy. The small patches of plain, among the long grass, most of them cultivated, and with mustard then in bloom, which induced the birds to feed, increased the beauty of the scene; and I speak within bounds when I assert that there could not be less than 1200 or 1500 peafowls, of various sizes, within sight of the spot where I stood for near an hour.' Sir James Emerson Tennent, also, in his work on Ceylon, says that 'in some of the unfrequented portions of the eastern province, to which Europeans rarely resort, and where the peafowl are unmolested by the natives, their number is so extraordinary that, regarded as game, it ceases to be "sport" to destroy them; and their cries at early morning are so tumultuous and incessant as to banish sleep, and amount to an actual inconvenience.'—The harsh cry of the P. seems to have been imitated in its Greek name *Taos*, and probably has given rise also to the Latin *Pavo* and the English *peacock*. The P., in a wild state, always roosts on trees, but makes its nest on the ground. When alarmed, as it feeds on the ground, it cannot readily take wing, and is sometimes run down by dogs or by horsemen.—The other species of P. is the JAPAN P. or JAVANESE P. (*P. Japonensis*, *Javanicus*, or *muticus*), a native of some of the south-eastern parts of Asia and neighboring islands. It is nearly equal in size to the Common P., but of less brilliant although very similar plumage. The cheeks and around the eyes are yellow; the neck, and other fore parts, greenish with golden reflections. The crest is longer than that of the Common P., its feathers less equal, and webbed along their whole length.

PEACOCK-STONE, the name under which the dry cartilaginous ligaments of some large lamellibranchiate molluscs, as the

pearl oyster, are sold by jewelers. They are used for ornamental purposes, although not so much as formerly; and far more on the continent of Europe, particularly in Portugal, than in Britain. They have opaline reflections, and are therefore sometimes called *Black Opal*.

PEA CRAB (*Pinnothere*), a genus of brachyurous crustaceans, with nearly circular and not very hard carapace. They are of small size, and interesting from their living within the mantle-lobes of lamellibranchiate molluscs, a circumstance which was well known to the ancients, and gave rise to many curious fables. A species (*P. veterum*) is very common in the *pinna* of the Mediterranean, and was imagined to render important services to its host in return for its lodging, keeping a lookout for approaching dangers, against which the blind *pinna* itself could not guard, and particularly apprising it, that it might close its shell when the cuttle-fish came near. It is curious to find this repeated by Haselquist, in the middle of last century, as a piece of genuine natural history. Whether the P. C. lives at the expense of the mollusc, and sucks its juices, is uncertain. It is certain that the flesh of such molluscs is palatable to pea crabs, and they eat it greedily in the aquarium. The friendship of the P. C. and the *pinna* is of course as fabulous as that of the lion and jackal, or of the rattlesnake, the owl, and the prairie-dog. A species of P. C. (*P. Pisum*) is very common within the mantle-lobes of the Common Mussel on the British coasts. Species are found in almost all parts of the world.

PEA MAGGOT, the caterpillar of a small moth (*Tortrix* or *Grapholitha pisi*), which lays its eggs in young pods of peas. The caterpillar lives in the pods, and eats the peas. This moth is very common in Britain, and in wet seasons the pods of peas are often found very full of its caterpillar.

PE'AN (Old Fr., *pannes*, furs), one of the furs born in Heraldry, differing from Ermine only in the tinctures: the ground being sable, and the spots of gold.

PEA ORE, a form of compact brown iron ore (hydrated peroxide of iron), consisting of round smooth grains, from the size of mustard-seed to that of small pease. Sometimes the grains are still smaller and flattish. This iron ore is very abundant in some places in France, and is smelted.

Peau.

PEAR (*Pyrus communis*), a tree of the same genus with the Apple (see *PYRUS*) and like it one of the most extensively cultivated and valuable fruit-trees of temperate climates. The leaves are ovate, serrated, smooth on both surfaces, and without glands; the flowers are produced in corymbs, which may almost be called umbels, and are smaller than those of the apple; the styles are distinct and not combined at the base, as in the apple; and the fruit is hemispherical at one end, tapering gradually away, more or less rapidly, to a point at the other. The pear-tree grows wild in woods and copses in Britain, on the continent of Europe, and throughout the temperate parts of Asia. In its wild state it is usually either a large shrub or a small tree, thorny, and with small austere fruit. In cultivation it is without thorns, becomes a tree of 40 or 50 feet high, sometimes more; and its stem attains a diameter of three feet. Cultivation has wrought even greater changes in the size and quality of its fruit. The pear has been cultivated from remote antiquity. Its cultivation was probably introduced into Britain by the Romans. The cultivated varieties are extremely numerous; and many new ones of great excellence have recently been produced. The *Jargonelle Pear* may be mentioned as one of the most esteemed of the varieties long known in Britain. Some of the kinds called *Bergamot* and *Beurré* are highly esteemed.

Many new kinds have recently been introduced into Britain from France and Belgium. The varieties of pear differ much in hardness and in fitness for particular soils; although a deep, moderately strong, dry, loamy soil is the best for this fruit. The finer varieties are cultivated in Britain as wall-trees. Pears succeed well as espaliers. They are generally grafted on seedling stocks of the wild pear, but sometimes on the rowan, and sometimes on the quince. Pears grafted on quince stocks are the best for shallow soils. The flowers and fruit of the pear are mostly produced on spurs, which spring from branches of more than one year old. Various modes of training and pruning are practised for pear-trees. Among the varieties of pears are some which ripen early in autumn, and some which do not ripen till the beginning of winter, and which even require to be mellowed by keeping for a short time; whilst some of the kinds cannot easily be kept for more than a few days. In general, pears cannot be kept so long nor so easily as apples. Pears are sometimes made into a preserve with syrup; and sometimes cut into pieces, and dried in the sun or in an oven, to be afterwards used in pies, a practice very prevalent in France.—A very agreeable fermented liquor called *Perry*

is made from pears, in the same manner as Cider from apples; and pear orchards for this purpose are to be seen in some parts of England, especially in Worcestershire and Herefordshire. The varieties of pear cultivated for making perry are all rather austere, and those which yield the best perry are far too austere to be palatable.—The wood of the pear-tree is reddish, very hard, fine-grained, and valuable to turners and joiners. It is often dyed black in imitation of ebony which it then greatly resembles.

Besides the varieties of pear usually referred to *Pyrus communis*, some are occasionally cultivated which are generally regarded as distinct species. Such are the **AURELIAN PEAR** (*P. salicifolia*), a native of France, with leaves much narrower than the common pear, and a long fruit which is used for making perry; the **SNOWY PEAR** (*P. nivalis*), a native of the Alps of Austria, with oval obtuse leaves, white and silky beneath, and a globose fruit, which is very acid till it becomes quite ripe, or is beginning to decay, when it is very sweet; the **SAND PEAR** (*P. sinensis*), a native of China and Cochín-China, with heart-shaped, shining, almost evergreen leaves, and apple-shaped warted fruit, very gritty, and fit only for baking, cultivated in gardens in India, but hardy in Britain. The **PASHIA** (*P. Pashia* or *P. variolosa*) is a native of the Himalaya; the fruit of which is only edible when blotted or partially decayed. The **PALTOO** (*P. lanata*) is another Himalayan species with edible fruit. Both are quite hardy in Britain.

PEAR, PRICKLY. See **PRICKLY PEAR**.

PEARL, a peculiar product of certain marine and fresh-water molluscs or shell-fish. Most of the molluscous animals which are aquatic and reside in shells are provided with a fluid secretion with which they line their shells, and give to the otherwise harsh granular material of which the shell is formed, a beautifully smooth surface, which prevents any unpleasant friction upon the extremely tender body of the animal. This secretion is evidently laid in extremely thin semi-transparent films, which, in consequence of such an arrangement, have generally a beautiful iridescence, and form in some species a sufficient thickness to be cut into useful and ornamental articles. The material itself in its hardened condition it called *nacre* by zoologists, and by dealers Mother-of-pearl (q. v.).

Besides the pearly lining of the shells, detached and generally spherical or rounded portions of the nacre are often found on opening the shells, and there is great reason to suppose these are the result of accidental causes, such as the intrusion of a grain of sand or other substance, which, by irritating the tender body of the animal, obliges it in self-defence to cover the cause of offence, which it has no power to remove; and as the secretion goes on regularly to supply the growth and wear of the shell, the included body constantly gets its share, and thereby continues to increase in size until it becomes a pearl. The Chinese avail themselves of the knowledge of this fact to compel one species of fresh-water mussel, *Unio Hyria*, to produce pearls. In order to do this, they keep the Unios in tanks, and insert between the shell and the mantle of the animal either small leaden shot or little spherical pieces of mother-of-pearl. These are sure to receive regular coatings of the nacreous secretion; and after a time look like pearls formed under ordinary circumstances. These curious people also practice another trick upon these animals; they insert small images of the Buddha stamped out of metal, which soon become coated with the pearl secretion, and are cemented by it to the shells; to those ignorant of its origin, the phenomenon is a supernatural testimony to the truth of Buddhism. Examples of these curiosities are to be found in many of our museums.

A plan of making pearls was suggested to the Swedish government by Linnæus. It consisted in boring a small hole through the shell of the river mussel, and inserting a grain of sand, so as to afford a nucleus for a pearl. The plan at first succeeded sufficiently well to prove its practicability, and he was rewarded by a sum of money (£450), but it failed as a profitable speculation, and was abandoned.

The exact nature of the secretion has never been satisfactorily determined; it is, however, ascertained that it is deposited in thin films, which overlap each other so irregularly, that their sharply serrated edges, when magnified, present the appearance represented in fig. 1; and to this peculiar disposition of the plates, the beautiful iridescence of common pearls is attributed. Their formation was a great puzzle to the ancients, amongst whom they were very highly prized. Dioscorides and Pliny mention the belief that they were drops of dew or rain which fell into the shells when opened by the animal, and were then altered by some power of the animal into pearls. This opinion, which obtained all over the east, is thus charmingly alluded to by Moore:

'And precious the tear as that rain from the sky,
Which turns into pearls as it falls in the sea.'

Fig. 1.

The most famous pearls are those from the east; the coast of Ceylon, or Taprobane, as it was called by the Greeks, having from the earliest times been the chief locality for pearl fishing. They are, however, obtained now of nearly the same quality in other parts of the world, as Panama in South America, St. Margarita in the West Indies, the Caromandel Coast, the shores of the Sooloo Islands, the Bahrein Islands, and the islands of Karak and Corgo in the Persian Gulf.

The pearls of the Bahrein fishery are said to be even finer than those of Ceylon, and they form an important part of the trade of Bassora. These, and indeed all the foreign pearls used in jewelry, are produced by the Pearl Oyster (q. v.). The shells of the molluscs which yield the Ceylon, Indian, and Persian ones, are sometimes as much as a foot in diameter, and are usually about nine inches. Those of the New World, although the shells are smaller and thicker, are believed to be the same species. The chief locality of the Ceylon pearl fishery is a bank about 20 miles long,

Fig. 2.

10 or 12 miles from shore, opposite to the villages of Condaty and Arippe on the northern coast. The season of the fishery lasts about three months, commencing at the beginning of February, and is carried on under government regulations. The boats employed are open, and vary in size from 10 to 15 tons burden; they put out at night, usually at 10 o'clock, on a signal gun being fired from the fort of Arippe, and make for the government guard vessel, which is moored on the bank, and serves the double purpose of a guard and a light-ship. The divers are under the direction of a manager, who is called the Adapanaar, and they are chiefly Tamils and Moors from India.

For each diver there is provided a diving-stone, weighing about 30 pounds, which is fastened to the end of a rope long enough to reach the bottom, and having a loop made for the man's foot; and in addition to this, a large network basket, in which to place the pearl oysters as he collects them. These are hung over the sides of the boat; and the diver, placing his foot in the loop attached to the stone, liberates the coils of the rope, and with his net-basket rapidly descends to the bottom. To each boat there is usually allotted a crew of 13 men and 10 divers, 5 of whom are descending whilst the others are resting. This work is done very rapidly; for, notwithstanding the stories to the contrary, the best divers cannot remain longer than 80 seconds below, and few are able to exceed 60. The greatest depth they descend is 13 fathoms, and the usual depth about 9 fathoms. When the diver gives the signal by pulling the rope, he is quickly hauled up with his net and its contents. Accidents rarely happen; and as the men are very superstitious, their safety is attributed to the incantations of their shark-charmers, performed at the commencement of the fishing. Sir E. Tennant, however, attributes the rarity of accidents from sharks, usually so abundant in tropical seas, to the bustle and to the excitement of the waters during the fishery frightening away those dreaded creatures. The divers are sometimes paid fixed wages, others agree for one fourth of the produce. When a boat load of oysters has been obtained, it returns to shore, and the cargo, sometimes amounting to 20,000 or 30,000, is landed and piled on the shore to die and putrify, in order that the pearls may be easily found.

The heaps are formed in small walled compartments, the walls surrounding each being about one or two feet in height. Several of these compartments surround a small central enclosure, in which is a bath, and they slope towards this bath, and are each connected with it by a small channel, so that any pearls washed out from the putrefying mass by the rain may be carried into the bath. When the animals in the shells are sufficiently decomposed, the washing commences, and great care is taken to watch for the loose pearls, which are always by far the most valuable; the shells are then examined, and if any attached pearls are seen, they are handed over to the clippers, who, with pinchers or hammer, skilfully remove them. Such pearls are used only for setting; whilst the former, being usually quite round, are drilled and strung, and can be used for beads, &c. The workmen who are employed to drill the pearls also round the irregular ones, and polish them with great skill. The method of holding the pearls during these operations is very curious; they make a number of

holes of small depth in a piece of dry wood, and into these they fit the pearls, so that they are only partly below the surface of the wood, which they then place in water. As it soaks up the water and swells, the pearls become tightly fixed, and are then perforated, &c. These operations are all carried on on the spot.

For many miles along the Condatchy shore, the accumulation of shells is enormous, and averages at least four feet in thickness. This is not to be wondered at, when it is remembered that this fishery has been in active operation for at least 2000 years. The place itself is exceedingly barren and dreary, and, except during the fishing season, is almost deserted; but at that time it presents an exceedingly animated spectacle; thousands of people, of various countries and castes, are here drawn together—some for the fishery, others to buy pearls, and others to feed the multitude. They chiefly reside in tents, so that it appears a vast encampment.

The pearls vary much in size; those as large as a pea, and of good color and form, are the best, except unusually large specimens, which rarely occur, the most extraordinary one known being the pearl owned by the late Mr. Hope, which measured two inches in length, and four in circumference, and weighed 1800 grains. The smaller ones are sorted into sizes, the very smallest being called seed-pearls. A considerable quantity of these last are sent to China, where they are said to be calcined, and used in Chinese pharmacy. Amongst the Romans, the pearl was a great favorite, and enormous prices were paid for fine ones. One author gives the value of a string of pearls at 1,000,000 sesterces, or about £8000 sterling. The single pearl which Cleopatra is said to have dissolved and swallowed was valued at £80,729; and one of the same value was cut into two pieces for earrings for the statue of Venus in the Pantheon at Rome. Coming down to later times, we read of a pearl, in Queen Elizabeth's reign, belonging to Sir Thomas Gresham, which was valued at £15,000, and which he is said to have treated after the fashion of Cleopatra; for he powdered it and drank it in a glass of wine to the health of the Queen, in order to astonish the ambassador of Spain, with whom he had laid a wager that he would give a more costly dinner than could the Spaniard.

During the occupation of Britain by the Romans this country became famous for its pearls, which were found in the fresh-water mussel of our rivers. See FRESHWATER MUSSEL. Generally the pearls of this mollusc are small, badly colored, and often valueless; but occasionally they occur of such beauty as to rival those of the pearl oyster. Some years ago, in the Scotch rivers, the search for pearls was prosecuted vigorously, especially by a merchant named Unger, of Edinburgh, who had brought Scotch pearls into great repute. He collected specimens ranging, as was stated, from £5 to £90 each, and formed a necklace said to be worth £350. In Scotch pearls of the highest quality, there is a pleasing pinkish tint, which is very permanent. The fishing for pearl mussels is by no means so dangerous or troublesome as for pearl oysters; usually they are found in the beds of streams, shallow enough to wade in, and so clear that they can be seen at the bottom. If too deep to remove with the hand, they are easily captured by putting a stick between their gaping shells, which instantly close upon it, and can be drawn out with it. So profitable did this pursuit become, that a great many persons engaged in it.

Very fine river pearls, known on the continent as Bohemian pearls, are found in the rivers Moldau and Wottawa. There is also a fresh-water pearl fishery in Bavaria, where the river Itz yields at times very fine specimens. Even the most inferior pearls have a market-value; for pearls can only be properly polished with pearl dust, and the inferior pearls are powdered for the purpose of polishing and rounding the finer ones.

False pearls are very admirable imitations, made by blowing very thin beads or bulbs of glass, and pouring into them a mixture of liquid ammonia, and the white matter from the scales of the Bleak, and sometimes of the Roach, and Dace. The proper way to prepare the pearl-matter is first to remove the scales of the lower part of the fish; these must then be very carefully washed, after which they are put to soak in water, when the pearly film falls off and forms a sediment at the bottom of the vessel, which is removed and placed in liquid ammonia for future use. This pearl mixture, when of the best quality, is very costly, being as much as £4 or £5 per ounce. For use, it is diluted with ammonia and injected into the glass beads, so as to thinly coat them inside; afterwards the better kinds have melted white wax poured in, which renders them much more durable. The French and Germans produce in this way imitations of the finest oriental pearls of such beauty, that the most practised eye can hardly detect the difference. The bleak is procured in considerable quantities for this purpose from the Thames and other rivers in England. See BLEAK.

The invention of artificial pearls is due to a Frenchman named Jaquin, in the time of Catharine de' Medici, and the manufacture is now chiefly carried on in the department of the Seine, where great improvements have lately been made, especially in the art

of giving the irregular forms of large pearls to the glass-bulbs, and thus increasing the resemblance, and in removing the glassy appearance caused by the exterior glass coating, by exposing it for a short period to the action of the vapor of hydrofluoric acid. Mucilage of fine gum-arabic is also used instead of wax, which increases the translucency, gives greater weight, and is not liable to melt with the heat of the wearer's body—a defect to which those filled with wax are very liable.

Roman pearls differ from other artificial pearls, by having the coating of pearly matter on the outside, to which it is attached by an adhesive substance. The art of making these was derived from the Chinese.

PEARL, a river of Mississippi, U.S., which rises about 100 miles north-north-east of Jackson, and, flowing south through the state, separates it in its lower course from Louisiana, and empties into Mississippi Sound, near the outlet of Lake Pontchartrain. It flows nearly 300 miles through a fertile cotton country, and is navigable to Jackson, the capital.

PEARL ASHES. See POTASH.

PEARL BARLEY. See BARLEY.

PEARL OYSTER (*Avicula* or *Meleagrina margaritifera*), a lamellibranchiate mollusc, of the family *Aviculidae*, generally found—great numbers together—attached to submarine rocks at a considerable depth on the coasts of tropical countries, and important as producing almost all the pearls and all the mother-of-pearl of commerce. It is sometimes called the PEARL MUSSEL; but the family to which it belongs differs considerably both from that of mussels and from that of oysters, the valves of the shell being unequal, the hinge-line straight and long, and the animal furnished with two adductor muscles, one of them small, and with a foot by which it produces a byssus. The P. O. is of an oblique oval form, longitudinally ribbed, and with concentric foliations when young which disappear when it is old. It attains a large size, and there are several varieties, the most important of which are noticed in the article MOTHER-OF-PEARL. The whole inside of the shell is covered with a thick layer of nacre or mother-of-pearl, compact and beautiful, forming indeed the chief part of the shell, and exhibiting very considerable variety of color, most frequently white, but sometimes blood-red. Pearls are formed of the same substance (see PEARL), and are generally, if not always, produced by eggs which have become abortive, and which remain lodged within the mollusc instead of being ejected into the sea.

The P. O. is too rank and coarse to be eaten. When taken from the sea it is commonly laid out in the sun to die, that the pearls may be sought for after the shell opens.

The P. O. is not the only mollusc which produces pearls. The *Placuna placenta*—an oyster (family *Ostreidae*) with thin transparent shell, which is used in China and elsewhere as a substitute for window glass—produces diminutive pearls. The Fresh-water Mussel (q. v.) of Britain produces pearls sometimes of considerable beauty and value; and instances have occurred of pearls being found in pinnæ, &c., and even in limpets.

PEARL SHELLS. See MOTHER-OF-PEARL.

PEARL WHITE. See WHITE COLORS.

PEARSON, JOHN, an English prelate of high celebrity, was born in 1612 at Snoring, in Norfolk, of which place his father was rector, educated at Eton and King's College, Cambridge, where he took the degree of M.A. in 1639, and in the same year took orders, and was collated to a prebend in Salisbury Cathedral. In 1640 he was appointed chaplain to Finch, lord-keeper of the great seal, and on the outbreak of the civil war became chaplain to Lord Goring, and afterwards to Sir Robert Cook, in London. In 1650, he was appointed minister of St. Clement's, Eastcheap, London; and in 1659, published the great work by which he is now remembered, *An Exposition of the Creed*. It was dedicated to his flock, to whom the substance of it had been preached some years before in a series of discourses. The laborious learning and the judicial calmness displayed by the author in this treatise have long been acknowledged, and command the respect even of those who think his elaborate argumentation tedious and not always forcible. It is generally reckoned one of the ablest works produced in the greatest age of English theology—the 17th century. During the same year, P. published *The Golden Remains of the Ever Memorable Mr. John Hales of Eton*.

At the Restoration, honors and emoluments were lavishly showered upon him. Before the close of 1660 he received the rectory of St. Christopher's, in London; was created D.D. at Cambridge; installed Prebendary of Ely and Archdeacon of Surrey; and made Master of Jesus College, Cambridge. In 1661, he obtained the Margaret professorship of Divinity, and was one of the most prominent commissioners in the famous Savoy conference; in 1662, he was made Master of Trinity, Cambridge, and in 1673, was promoted to the bishopric of Chester. The year before he had published his *Vindiciae Epistolarum S. Ignatii*, in answer to

M. Dailè, who had denied the genuineness of the epistles. It was imagined for years that P. had triumphed over his opponent. The history of the controversy, however (see *IGNATIUS*), has shown that Dailè was right and P. wrong. In 1684, appeared his *Annales Cypriani*. He died July 16, 1686. P.'s *Opera Posthuma Chronologica*, were published by Dodwell (Lond. 1688), and his *Orationes, Conciones et Determinationes Theologice* contain much valuable matter, for, as Bentley used to say, P.'s 'very dross was gold.' Bishop Burnet thought him 'in all respects the greatest divine of his age.'

PEASANT WAR, in German history, the name given to that great insurrection of the peasantry which broke out in the beginning of the year 1525, and which Zschokke has described as the 'terrible scream of oppressed humanity.' The oppression of the peasants had gradually increased in severity, as the nobility became more extravagant and the clergy more sensual and degenerate. The example of Switzerland encouraged the hope of success, and from 1476 to 1517 there were risings here and there amongst the peasants of the south of Germany. A peasant rebellion, called from its cognizance, the *Bundschuh* (Laced Shoe), took place in the Rhine countries in 1502, and another, called the 'League of Poor Conrad,' in Württemberg, in 1514, both of which were put down without any abatement of the grievances which occasioned them. The Reformation, by the mental awakening which it produced, and the diffusion of sentiments favorable to freedom, must be reckoned amongst the causes of the great insurrection itself; although Luther, Melancthon, and the other leading reformers, whilst urging the nobles to justice and humanity, strongly reprobated the violent proceedings of the peasants. The Anabaptists, however, and in particular Münzer, encouraged and excited them, and a peasant insurrection took place in the Hegau in 1522. Another, known as the 'Latin War,' arose in 1523 in Salzburg, against an unpopular archbishop, but these were quickly suppressed.

On January 1, 1525, the peasantry of the abbacy of Kempten, along with the townspeople, suddenly assailed and plundered the convent, compelling the abbot to sign a renunciation of his rights. This proved the signal for a rising of the peasants on all sides throughout the south of Germany. Many of the princes and nobles at first regarded the insurrection with some measure of complacency; because it was directed in the first instance chiefly against the ecclesiastical lords; some, too, because it seemed likely to promote the interests of the exiled Duke of Württemberg, who was then upon the point of reconquering his dominions by the help of Swiss troops; and others, because it seemed to set bounds to the increase of Austrian power. But the Archduke Ferdinand hastened to raise an army, the troops of the empire being for the most part engaged in the emperor's wars in Italy, and intrusted the command of it to the Truchsess von Waldburg, a man of stern and unscrupulous character, but of ability and energy. Von Waldburg negotiated with the peasants in order to gain time, and defeated and destroyed some large bodies of them, but was himself defeated by them on the 22d of April, when he made a treaty with them, not having, however, the slightest intention of keeping it.

Meanwhile the insurrection extended, and became general throughout Germany, and a number of towns took part in it, as Heilbronn, Mühlhausen, Fulda, Frankfurt, &c., but there was a total want of organization and co-operation. Towards Easter, 1525, there appeared in Upper Swabia a manifesto, which set forth the grievances and demands of the insurgents. They demanded the free election of their parish clergy; the appropriation of the tithes of grain, after competent maintenance of the parish clergy, to the support of the poor and to purposes of general utility; the abolition of serfdom, and of the exclusive hunting and fishing rights of the nobles; the restoration to the community of forests, fields, and meadows, which the secular and ecclesiastical lords had appropriated to themselves; release from arbitrary augmentation and multiplication of services, duties, and rents; the equal administration of justice; and the abolition of some of the most odious exactions of the clergy. The conduct of the insurgents was not, however, in accordance with the moderation of their demands. Their many separate bands destroyed convents and castles, murdered, pillaged, and were guilty of the greatest excesses, which must indeed be regarded as partly in revenge for the cruelty practised against them by Von Waldburg. A number of princes and knights concluded treaties with the peasants conceding their principal demands. The city of Würtzburg joined them, but the Castle of Leibfrauenberg made an obstinate resistance, which gave time to Von Waldburg and their other enemies to collect and strengthen their forces. In May and June 1525, the peasants sustained a number of severe defeats, in which large bodies of them were destroyed.

The Landgraf Philip of Hesse was also successful against them in the north of Germany. The peasants, after they had been subjugated, were everywhere treated with terrible cruelty. In one

instance a great body of them were perfidiously massacred after they had laid down their arms. Multitudes were hanged in the streets, and many were put to death with the greatest tortures. Weinsberg, Rothenburg, Würtzburg, and other towns which had joined them, suffered the terrible revenge of the victors, and torrents of blood were shed. It is supposed that more than 150,000 persons lost their lives in the Peasant War. Flourishing and populous districts were desolated. The lot of the defeated insurgents became harder than ever, and many burdens of the peasantry originated at this period. The cause of the Reformation also was very injuriously affected. See Sartorius *Versuch einer Geschichte des Deutschen Bauernkriegs* (Berl. 1795); Ochsle, *Beiträge zur Geschichte des Deutschen Bauernkriegs* (Heilbronn, 1829); Wachsmuth, *Der Deutsche Bauernkrieg* (Leip. 1834); and Zimmermann, *Allgemeine Geschichte des grossen Bauernkriegs* (3 vols. Stuttg. 1841—1843).

PEA-STONE, PI'SOLITE, or PI'SIFORM LIMESTONE, is a kind of calcareous spar or limestone, which occurs in globules from one-eighth of an inch to half an inch in diameter, imbedded in a cement of similar substance. There is generally a grain of sand in the center of each globe as the nucleus, around which it has been formed, and the concentric plates of its structure are easily visible. Sometimes the nucleus is merely a bubble of air. P. is found in great masses near the hot springs of Carlsbad, in Bohemia. It is sometimes used for ornamental purposes.

PEAT, a substance formed by the decomposition of plants amidst much moisture, as in marshes and morasses; and sometimes described as a kind of *Humus* (q. v.), formed by the accumulation of the remains of mosses and other marsh-plants. The remains of the plants are often so well preserved in it, that the species can be easily distinguished. Reeds, rushes, and other aquatic plants may usually be traced in peat, and stems of heath are often abundant in it; but it chiefly consists, in the northern parts of the world, of different species of *Sphagnum* (q. v.), or Bog-moss. Mosses of this genus grow in very wet situations, and throw new shoots in their upper parts, whilst their lower parts are decaying and being converted into peat; so that shallow pools are gradually changed into bogs. It was at one time believed that bogs owed their origin to the destruction of forests, the fallen trees impeding the natural drainage, and causing the growth of those marsh-plants of which peat is formed; and this theory was supported by reference to instances supposed to be authenticated by tradition—as that of the moor of Hatfield in Yorkshire, now consisting of about 12,000 acres of peat, and said to have been a forest of firs, till 'the Romans under Ostorius, having slain many Britons, drove the rest into the forest,' which was then destroyed by the victors.

There are, however, satisfactory proofs that peat has accumulated in many places around trees; and firs remaining in their natural position have been found to have six or seven feet of peat under their roots, although other trees, as oaks, are commonly found with their stumps resting on the soil beneath the peat. Yet it is not improbable that the destruction of forests may, in some instances, by impeding the course of the streams which flowed through them, have caused the stagnation of water from which the growth of peat resulted. Some of the largest mosses and fens of Europe occupy the place of forests, which were destroyed by order of Severus and other Roman emperors; and some of the British forests, now mosses, as well as some of those of Ireland, were cut because they harbored wolves or outlaws. The overthrow of a forest by a storm in the 17th c., is known to have caused the formation of a *peat-moss* near Loch Broom, in Ross-shire. Layers of trees are not unfrequently found in peat, which seem to have been suddenly deposited in their horizontal position, and sometimes to have been felled by human hands. It is not improbable, however, that sometimes peat has been formed where the soil has been exhausted by the long-continued growth of one kind of tree. The growth of peat is often rapid: bogs have been known to increase two inches in depth in a year. The surface of a bog sometimes becoming a floating mass of long interlaced fibres of plants, known in Ireland as *Old Wives' Toss*. The vegetation on the surface is sometimes very green and compact, like a beautiful turf.

Peat is vegetable matter more or less decomposed, and passes by insensible degrees into Lignite (q. v.). The less-perfectly decomposed peat is generally of a brown color; that which is more perfectly decomposed is often nearly black. Moist peat possesses a decided and powerful antiseptic property, which is attributed to the presence of gallic acid and tannin, and is manifested not only in the perfect preservation of ancient trees and of leaves, fruits, &c., but sometimes even of animal bodies. Thus, in some instances, human bodies have been found perfectly preserved in peat, after the lapse of centuries.

The formation of peat may be regarded as one of the most important geological changes now in evident progress. It takes place, however, only in the colder parts of the world. In warm

regions, the decay of vegetable substances, after life has ceased, is too rapid to permit the formation of peat. The surface covered by peat is very extensive in all the colder parts of the world; although in the southern hemisphere no moss seems to enter into its composition; and the South American peat is said by Mr. Darwin to be formed of many plants, but chiefly of *Astelia pumila*, a phanerogamous plant of the rush family. The surface covered by peat even in England is considerable; it is greater in Scotland, and very great in Ireland. Extensive tracts are covered with peat even in the southern countries of Europe, and sometimes even near the sea; and in more northern regions, the mosses or bogs are still more extensive. For their physical characters, and the mode of reclaiming them, or converting them into arable land, see Bog.

Mere peat is not a good soil, even when sufficiently drained, but, by the application of lime, marl, &c., it is soon converted into good soil, yielding excellent crops. A mixture of peat is often of benefit to soils otherwise poor. And for many shrubs, as rhododendrons, kalmias, wortleberries, &c., no soil is so suitable as one in great part composed of peat; which is therefore in much request with gardeners in order to the formation of the soil for certain kinds of plants.

Peat is extensively used for fuel. The more perfectly decomposed the vegetable matter is, and the more consolidated that the peat therefore is, the better it is suited for this use. It is the ordinary fuel of great part of Ireland, and is there almost always called *turf*, although the term *turf*, in its ordinary English sense, is utterly inapplicable to it. To procure peat for fuel, the portion of bog to be operated upon must first be partially dried by a wide open drain; its surface is then paired off with the spade, to the depth of about six inches, to remove the coarse undecomposed vegetable matter; the peat is afterwards cut out in pieces (peats) like bricks, by means chiefly of a peculiar implement, called in Ireland a *slane*, and in Scotland a *peat-spade*, resembling a long, narrow, sharp spade, the blade of which is furnished on one side with a tongue set at a right angle to it. This implement is used by the hands alone, without pressure of the foot. The soft peats are conveyed to some neighboring place, where they are set up on end in little clusters to dry.

When sufficiently dry, they are conveyed away, and may be piled in outhouses or stacked in the open air. The operation of *peat-cutting* is always performed in spring or summer.—Where peat for fuel cannot be obtained in the way just described, the black mud of a semi-fluid bog is sometimes worked by the feet of a party of men, women, and children until it acquires such a consistency that it can be moulded by the hand. The process is laborious, but the fuel obtained by it is good.—In countries depending on peat for fuel, a very rainy season sometimes occasions great inconvenience, and even distress, by preventing the cutting and drying of the peat.

Peat is a light and bulky kind of fuel, and cannot be conveyed to considerable distances without too great expense. Efforts have, however, been made, both in Scotland and Ireland, to render it more generally useful, and so to promote the reclaiming of bogs, by compressing it until its specific gravity is nearly equal to that of coal. For this purpose, it is first reduced to a pulp. The compressing of peat has not yet been advantageously prosecuted on an extensive scale.

Peat-charcoal, made from uncompressed peat, is very light and inflammable, and therefore unsuitable for many purposes, but for others it is particularly adapted, and no kind of charcoal excels it in antiseptic and deodorizing properties. It is also an excellent manure for many kinds of soil, and great crops have often been obtained by its use. Peat-charcoal is highly esteemed for the smelting of iron, and for working and tempering the finer kinds of cutlery. Charcoal made from compressed peat is in density superior to wood-charcoal, and is capable of being used as coke. The Irish Amelioration Society, some years ago, encouraged the conversion of peat into charcoal, but it seems not to have paid as a commercial speculation, although the resulting charcoal was of good quality. Various companies have been formed for the purpose of obtaining valuable products from the destructive distillation of peat. It appears from researches of Sir R. Kane and others, that 1000 parts of peat yield about 11 of sulphate of ammonia, 7 of acetate of lime, 2 of wood naphtha, 1 of paraffin, 7 of fixed oil, and 3 of volatile oil. The manufacture has not, however, as yet proved sufficiently profitable to be generally adopted, although the distillation of peat has, we believe, been carried on for some years at Athy, near Kildare. For further details on this subject, the reader is referred to a parliamentary *Report on the Nature and Products of the Destructive Distillation of Peat*, published in 1851, and to a paper by Dr. Paul in the 6th volume of *The Chemical News*. A more recent contribution to the subject is *The Peat Mosses of Buchan*—by the Rev. James Peter, minister of Deer (Aberdeen, 1875).

Flower-pots are sometimes made of peat. It is easy to transplant flowers growing in them without loosening the earth from the

roots, the pot being readily cut to pieces; and liquid manure applied outside finds its way sufficiently to the roots.

PEA WEEVIL (*Sitona crinita* and *S. lineata*), small coleopterous insects, about a quarter of an inch long, which are very destructive to crops of peas and other kinds of pulse, devouring the leaves and other succulent parts, often soon after the plants appear above ground. Lime, soot, or wood ashes dusted over the plants, protect them in some measure from the ravages of these insects; and hoeing or other stirring of the soil is beneficial, probably by destroying the eggs, larvae, and pupæ.

PEBBLE (probably allied to *bubble*, from the sound of water running among stones), a small round, water-worn stone of any kind; but with jewelers sometimes an agate—agates being often found as loose pebbles in streams, and those of Scotland in particular being popularly designated *Scotch Pebbles*. Hence the name has come even to be extended to rock-crystal, when not in the crystalline form, and we hear of spectacles with eyes of pebble, &c. Deposits of pebbles (in the sense of water-worn stones), occur among the rocks of all periods, but the pebbles are seldom loose; they are generally cemented together by iron, lime, or silex, forming a pudding-stone of greater or less hardness. Single pebbles are sometimes found in deposits which have been formed at a distance from currents in perfectly still water, as in chalk and fine silt. They must have been floated to their places entangled in the roots of trees, or attached to the roots of large buoyant sea-weeds.—**BRAZILIAN PEBBLES** (so called from Brazil having been long famous for the purity of its rock crystal), are very pure pieces of Rock Crystal (q. v.), used by opticians for making the lenses of spectacles, &c.

PECCARY (*Dicotyles*), a genus of *Pachydermata*, of the family *Suidæ*, much resembling hogs; but having a mere tubercle instead of a tail; only three toes—no external toe—on the hind-feet; the molar teeth and incisors very like those of hogs, but the canine teeth not nearly so long, and not curving outwards. An approach to ruminants is seen in the stomach, which is divided into several sacs; also in the union of the metacarpal and metatarsal bones of

Peccary (*Dicotyles torquatus*.)

the two greater toes into a kind of cannon bone. A glandular opening on the loins, near the tail, secretes a fetid humor. Only two species are known, both natives of South America; and except the tapirs, the only existing pachydermata of the American continent.

The **COMMON P.**, **COLLARED P.**, or **TAJACU** (*D. torquatus*), is found in almost all parts of South America; the **WHITE-LIPPED P.** (*D. labiatus*) is found in many parts of it. Both are gregarious; the White-lipped P., often assembling in very large herds, and sometimes doing great mischief to maize and other crops. The herds of the White-lipped P. seem to follow a leader, like those of ruminants. The Common P. chiefly frequents forests, and small companies sometimes take up their abode in the hollow of a great tree. The Common P. is about the size of a small hog, grayish; the hairs alternately ringed with black and yellowish white, bristly; and on the neck longer, and forming a mane. A narrow white collar surrounds the neck. The White-lipped P. is considerably larger, of a darker color, with conspicuously white lips. The ears are almost concealed by the hair. Both species are capable of being tamed, but are of irritable and uncertain temper. In a wild state they defend themselves vigorously against assailants, making good use of their sharp tusks, and a whole herd combine for defence. The hunter has often to take refuge from them in a tree. They are omnivorous; and if hurtful to crops, render service by destroying reptiles. Their voice is somewhat like that of the hog, but more sharp. Their flesh resembles that of the hog, but is said to be inferior. The glands on the loins must be cut out immediately after the P. is killed, or their fetid humor infects the whole flesh. No attempts seem yet to have been made for the economic domestication of the peccaries.

PE-CHIH-LE'. See **CHIH-LE**.

PECK, a measure of capacity for dry goods, such as grain, fruit, &c., used in Britain, and equivalent to 2 imperial gallons,

or 554-548 cubic inches. It is thus the fourth part of a Bushel (q. v.). The old Scotch peck, the 16th part of a boll, when of wheat, was slightly less than the imperial peck; but when of barley, was equal to about 1-456 of it.

PECORA (Lat. cattle), a Linnæan order of Mammalia, now generally called RUMINANTIA (q. v.).

PECOS, a river of Texas, U. S., rises in the mountains near Santa Fé, New Mexico, runs south-easterly 600 miles through New Mexico and Texas, and flows into the Rio Grande-del-Norte, in lat. about 29° 30' N., long. 102° W.

PECTEN, a genus of lamellibranchiate molluscs, commonly referred to the same family with the oyster (*Ostrea*), which is sometimes called *Pectinida*. The shell has neither teeth nor laminae in the hinge; the valves are unequal, one of them being often much more convex than the other; the shape is regular; the hinge is extended by ears, and in most of the species both valves have ribs radiating from the umbo to the margin. Hence the name

Pecten.

pecten (Lat. a comb), from the appearance which they present. The animal has a small foot; some of the species are capable of attaching themselves by a byssus; they are capable also of locomotion by opening and rapidly closing the valves, and in this way can even regain the sea from a short distance by leaping on the shore. Some of the larger species are often popularly called *clams*, a name shared by other bivalves. *P. Jacobus*, a native of the Mediterranean, is the SCALLOP-SHELL

which pilgrims were accustomed to wear in front of their hat, in token of their having visited the shrine of St. James at Compostella. It attains a size of about 4 inches long and 5 inches broad. *P. maximus*, found on many parts of the British coasts, is about 6 inches broad. It is sometimes eaten, but is hard and indigestible. Several other species are British. Species are found in almost all parts of the world.

PECTIC ACID AND PECTINE. See FRUITS.

PECTINIBRANCHIATA (Lat. comb-gilled), an order of gasteropodous molluscs, having the gills composed of numerous leaflets or fringes, arranged like the teeth of a comb, and affixed to the internal surface of a cavity which opens with a wide opening above the head. The sexes are distinct. All the P. have two tentacles and two eyes, the eyes often stalked. The mouth is produced into a proboscis, more or less lengthened. The eggs are deposited in a mass, with an envelope often of very remarkable and complicated form, which is produced by coagulation of a viscous albuminous matter secreted by a peculiar gland of the female. The P. are very numerous; the greater number of gasteropods being included in this order; some have a siphon, and some are destitute of it; some have spiral, and some have simply conical shells. Almost all are inhabitants of the sea or its shores; a few are found in fresh water. To this order belong Whelks, Periwinkles, Cones, Volutes, *Calyptraea*, &c.

PECTORILOQUY is a term of such frequent occurrence in the history of chest diseases as to require a brief notice in this work. If the stethoscope be applied to the chest of a healthy person, and he be requested to speak, the sounds of his voice will be conveyed to the ear of the observer with very different degrees of clearness, according to the part of the chest on which the base of the instrument rests. If, for example, it be applied at the top of the sternum or breast-bone the voice will reach the ear, through the tube with tolerable distinctness. For a short distance on either side of the sternum, just below the collar-bones, and in the arm-pits, the voice is still heard, but the sound is indistinct and confused. Below the third rib, and over the remainder of the chest, the voice only produces an obscure thrilling sound which is known as *pectoral resonance*. In certain morbid conditions the sounds of the voice seem to proceed with distinctness from the walls of the chest directly into the ear; and then, in place of the normal pectoral resonance, we have the physical sign known as Pectoriloquy (from the Latin *pectore*, from the chest, and *loquor*, I speak). It occurs when a tolerably superficial excavation, of moderate or considerable size, lies under the stethoscope; and hence it was at one time regarded as an almost certain indication of advanced consumption, but it is now known that it may also occur when solidified masses of lung lie between a large bronchial tube and the part of the chest on which the instrument rests.

PECULIAR (Fr. *peculier*, i. e., private) is, in English Law, a particular parish or church having jurisdiction within itself, and exempt from the jurisdiction of the ordinary. The Courts of Peculiars in these jurisdictions amount to about 300 in England and Wales, and had jurisdiction in reference to probates of wills before the recent constitution of the Court of Probate. Their jurisdiction is still somewhat obscure.

PEDAL (Lat. *pes*, a foot), any part of a musical instrument acted on by the feet. The pianoforte, the harp, and the organ are furnished with pedals, which, however, serve an entirely different purpose in each instrument. In the pianoforte, their object is to effect a change in the quality or intensity of the sound; the damper pedal prolongs the sound after the finger is lifted from the key, and the shifting or *una corda* pedal softens the tone. The pedals of the harp are the means by which the chromatic changes of intonation are effected. In the organ, the pedals are keys put in action by the feet. The division of the organ which is connected with the foot-keys is called the pedal-organ, and contains the largest pipes. The introduction of pedals in the organ is assigned to a German of the name of Bernhard, who flourished in the 15th c.; they were long of being brought into use in England, but now few organs, except those of the smallest dimensions, are made without them. Pedals are also used in the organ to act on the swell and on the stops. See ORGAN.

PEDALIA'CEÆ. See BIGNONIACEÆ.

PEDAL-POINT, or PEDAL HARMONY. See ORGAN-POINT.

PEDEE', GREAT, a river of North and South Carolina, U. S., rises in the Alleghany Mountains, in the north-west of North Carolina, and running south by east flows through the east portion of South Carolina, and enters the Atlantic through Win-yaw Bay at Georgetown. It is navigable to Cheraw, 150 miles, and is about 350 miles in length.—The LITTLE PEDEE, its principal eastern branch, is formed by the confluence of several smaller rivers in the south part of North Carolina.

Pedestal.

PEDESTAL, a base or block on which columns, statues, &c., are frequently set. The pedestal is much used in classic architecture. Like the column, it has a base, *a*, and a sort of capital or cornice, called the surbase, *c*. The shaft, or plain block, *b*, is called the dado or die.

PEDETES, or HE'LAMYS, a genus of rodent quadrupeds of the family *Murida*, allied to Jerboas, but differing from them in some of the characters of their dentition. The hind-legs, although very long, are not so long as in the jerboas. The tail is long. The JUMPING HARE (*P.* or *H. Capensis*) of South Africa is about the size of a rabbit. It can jump 20 or 30 feet at a bound. Its fore-feet are also very strong, and it burrows very expeditiously. The claws are long and strong. The habits of the animal are nocturnal, and it does considerable mischief in corn-fields and gardens.

PEDICELLA'RIÆ are very remarkable minute appendages of the integuments of many of the Echinodermata, having the form of a stalk, with a small two-bladed or three-bladed forceps at its summit. They are of a fleshy substance, with calcareous granules imbedded, and in a living state the blades are continually opening and closing. They were at one time supposed to be parasitic zoophytes, but are now generally believed to be organs of the starfish or sea-urchin, although their use is merely conjectured to be that of keeping the surface of the echinoderm free of algae and zoophytes. The introduction of a pin's point between the blades causes an immediate closing of them. They are found both on shelly and on comparatively soft integuments, and are always present, and always of a particular form, according to the species of echinoderm, and according to the particular place which they occupy, being crowded chiefly around the spines, and near the mouth of sea-urchins.

PEDICULARIS, a genus of herbaceous plants of the natural order *Scrophulariaceæ*, some of which have rather large and finely-colored flowers. Two species, *P. palustris* and *P. sylvatica*, are natives of Britain, common in wet grounds. Both have received the name of Lousewort, the English equivalent of '*pedicularis*,' from their supposed influence in producing the lousy disease in sheep; an influence purely imaginary. Their acridity renders them injurious to sheep which eat them. Continental Europe and the northern parts of Asia produce many other species, and some are found in North America. *P. sceptrum*, or King Charles's Sceptrum, is one of the principal ornaments of marshy grounds in the most northern countries of Europe.

PEDI'CULUS. See LOUSE.

PEDIGREE (probably from Lat. *pes*, a foot), a tabular view of the members of a particular family with the relations in which they stand to each other, accompanied or unaccompanied by a notice of the chief events in the life of each, with their dates, and the evidence of the facts stated. Pedigrees are indispensable aids to the student of history. The wars of the Roses, the claim of Edward III. to the crown of France, the relative position of Mary and Lady Jane Grey, the circumstances which brought about the union of the crowns of England and Scotland, the Slesvig-Hol-

stein question, which occupied the attention of all Europe, and many other familiar chapters in the history of nations, as well as of families, cannot be read aright without the aid of pedigrees. The materials to be used in the formation of a pedigree are notes of the facts to be set forth, and a recognized series of signs and abbreviations. These notes comprise the name of every person who is to appear in the pedigree, with such dates and circumstances as it may be considered desirable to record.

Among the commonest abbreviations are *da.*, for daughter of; *s.* and *h.*, son and heir of; *coh.*, coheir of; *w.*, wife of; *s. p.* (*sine prole*), without issue; *v. p.* (*vita patris*), in his father's lifetime; *b.*, born, *d.*, died; *dep.*, deposed; *K.*, king; *E.*, earl, &c. The sign = placed between two names, indicates that they were husband and wife; $\perp$ indicates that they had children; under a name signifies that the person had children. All persons of the same generation are to be kept in the same horizontal line; and the main line of descent is, wherever possible, to be indicated by keeping the successive names in a vertical column. Continuous lines indicate the succession of the different generations. The members of the same family are generally arranged in their order of birth in two groups—the sons first, and then the daughters; but where the same father or mother has children by more than one marriage, the children of each marriage ought to form distinct groups. The actual arrangement, however, of a pedigree must always depend on the leading object which it is intended to illustrate.

Tabular genealogies, generally brief, and meant to illustrate some particular claim of right, are found among the records, public and private, of the early middle ages; but after the incorporation of the English Heralds' College, far more attention was devoted to the compilation of pedigrees of families, more particularly with reference to their claims to dignities and heraldic insignia. In the course of the 16th c., the heralds obtained copies of all such accounts of the English families of any distinction as could be supplied to them, and entered them in the books which contain the records of their official proceedings. Royal commissions were issued under the Great Seal to the two provincial king-of-arms, empowering them to visit in turn the several counties of England, in order to collect from the principal persons of each county an account of the changes which had taken place in their respective families in the interval since the last preceding visitation, and to inquire what account could be given of themselves by families who had stepped into the rank of gentry, or had become settled in the county since that period. The register-books kept by the heralds and their assistants contain the pedigrees and arms collected in the course of the visitations, with the signatures of the heads of the families. The pedigrees thus collected contain a vast body of information, interesting not only to the professed genealogist, but to every one who would know anything of the distinguished characters in English history. Some of these books are lost, the rest are scattered among the public and private libraries of the country, the largest collections being in the archives of the College of Arms and the British Museum.

After the beginning of last century, the visitations were discontinued, and there has since been no official and regular collection of pedigrees. A standing order of the House of Lords, in 1767, required that before any peer should be allowed to take his seat, Garter-king-of-Arms was to deliver at the table of the House of Lords a pedigree of his family, to be verified by the Committee of Privileges, and eventually preserved in the records of the House, a copy being also registered in the College of Arms. This order was rescinded by Lord Thurlow in 1803, with the view of framing a new one; but, unfortunately, this was never done. Persons sensible of the importance of preserving an authentic account of their descent, frequently record their pedigrees for preservation in the Register of the College of Arms. This register is quite distinct from the heraldic department of that institution, and is open to any one who wishes to preserve evidence of any properly authenticated facts regarding his descent and family.—In Scotland, in the absence of the regular system of visitations which prevailed in England, there is a great deal of evidence regarding the pedigrees of the historical families of the country scattered here and there in public and private collections, including the Advocates' Library and Lyon Office.

A register of genealogies, similar to that of the English Heralds' College, exists in the Lyon Office, in which the pedigrees of applicants, after being proved to the satisfaction of the heraldic authorities, are inserted with the accompanying evidence. 'To what extent the register of genealogies in the Lyon Office may be admitted as a probative document, conclusive of the facts which it sets forth, has not been ascertained by actual decision; but there can be no doubt that, in questions both as to property and honors, it would be regarded as a most important adminecle of proof. The genealogical department of the Heralds' College in London is a very important one, and it is to be regretted that the uses of the corresponding department of the Lyon Office are so little understood and appreciated by the public.'—*Lorimer's Handbook of the Law of Scotland*, 2d edit., p. 446.

PEDIGREE, in point of law, is the legal relationship between individuals which is looked to with regard to the descent of property and honors. The occasion in which it comes into question is where a person dies, in which case his property, if he died intestate, is divided among those who are related by blood. The real property goes to one set of relations, and the personal property to others. See *INTESTACY*, *NEXT OF KIN*, *SUCCESSION*, *Paterson's Comp. of English and Scotch Law*, 251, 257.

PE'DIMENT, the triangular space over the portico at the ends of the roof of classic buildings. It is enclosed by the horizontal and the *raking* cornices, the latter of which follow the slopes of the roof. The pediment may be called the gable of classic buildings. It is frequently enriched with sculpture, for which it forms a fine setting. The doors and windows of classic buildings are often surmounted by pediments, either straight-sided or curved.

PEDLERS. See *HAWKERS*.

PEDO'METER, an instrument for measuring walking distances. It sometimes has a watch or clock attached. In the patent pedometer of Messrs. Payne, William, & Co., there is a repeating watch, which shows seconds, minutes, and hours, and also the day of the month. They are used by pedestrians, and for measuring streets when the fares of hired carriages are disputed. See *ODOMETER*.

PEDRO I. (DOM PEDRO D'ALCANTARA), Emperor of Brazil, was the second son of John VI. king of Portugal, and was born at Lisbon, 12th October 1798. On the death of his elder brother in 1801, he became Prince of Beja, and heir to the throne; and after his father's accession to the throne of Portugal and Brazil in 1816, he received the title of Prince of Brazil. He was carried along with the rest of the royal family of Portugal in their flight to Brazil in 1807, and from that time remained in that country. His education, owing to political disturbances, was not carried on systematically, and after his arrival in Brazil, he was left to instruct himself very much according to his own inclination. In 1817, he married the Archduchess Leopoldine of Austria, and on his father's return to Lisbon in 1821, was named Regent of Brazil. At this time, a great political crisis was impending; the Brazilians had been utterly disgusted at the preferment of Portuguese to the highest offices of state and the chief clerical dignities, and their discontent was heightened by the refusal of the Portuguese Cortes to accord to Brazil a liberal constitution similar to that which had been granted to the mother-country, and by its arbitrary command, that P., who was at the head of the liberal party, should at once return to Portugal to complete his education.

P., however, cast in his lot with the Brazilians, despite threats of exclusion from the throne of Portugal, and was chosen, on 12th October 1822, Emperor of Brazil. His government was very vigorous, but a war which broke out between his supporters and the advocates of republicanism, distracted the country for a time, and prevented the liberal measures of the government from taking full effect. In 1825, his title was recognized by the Portuguese Cortes; and the death of his father, in the following year, opened for him the succession to the throne of Portugal. This revived the national spirit of the Brazilian Chambers, who feared that they were about to be again reduced to a dependent state, and P.'s hasty and passionate temper led him to measures which whetted the general discontent. But he merely retained the dignity of king of Portugal long enough to show his right to it, and, after granting a more liberal constitution, immediately resigned in favor of his daughter, Maria II. The disturbances in Brazil still increased, the finances fell into disorder, the emperor's second marriage with the Princess Amelia of Leuchtenburg displeased his subjects; and after making various ineffectual attempts to restore tranquility, he was compelled, by the revolution of July 1831, to resign the throne in favor of his son, Pedro II., a boy of 5½ years old. P. then sailed for Portugal, where his brother Miguel had usurped the throne; and with the aid of an army which was swelled by French and English volunteers, after a three years' campaign, he drove away the usurper, and restored his daughter to the throne in 1834. But the ceaseless excitement by which he had been surrounded, and the excessive demands on his energies, had produced total exhaustion, and he died 24th September 1834. See *BRAZIL*; *MIGUEL*; *DOM*; and *PORTUGAL*.

PEDU'NCLE. See *FLOWER*.

PEEBLES. See *PEEBLESSHIRE*.

PEEBLESSHIRE, a county in the south of Scotland, also called Tweeddale, from consisting mainly of the upper valley of the Tweed, a river which originates in the county. P. is bounded by Dumfries and Selkirk shires on the S., Lanarkshire on the W., Mid-Lothian on the N., and Selkirkshire on the E. The county is small, containing only 356 square miles, or 227,869 statute acres. Its lowest point above the mean level of the sea is about 450 feet, from which to 1200 feet is the region of cultivation; but the county being a group of hills, is mostly pastoral, with the arable lands chiefly in the valleys. The highest hill is Broad

Law, which reaches an elevation of 2761 feet. Within the county, the Tweed has for tributaries the small rivers Eddleston, Leithen, Quair, Manor, and Lyne, besides many mountain rivulets. P. comprehends sixteen parishes, but several being ecclesiastically united, the number of parish churches, each with a settled minister, is fourteen; the number of parish schools is fifteen. The only town in the county is Peebles, an ancient royal burgh, pleasantly situated on a peninsula formed at the confluence of the Eddleston with the Tweed. The principal villages are Innerleithen, Walker Burn, West Linton, and Carlups.

In 1881, the population of the county was 13,819, of whom 4059 belonged to Peebles, which, distant 22 miles from Edinburgh, is the seat of a sheriff and county administration. It is also the seat of a presbytery. Besides the parish church, the town has several dissenting places of worship, including an Episcopal and a Roman Catholic chapel. It likewise possesses some good schools, has three branch banks, and a number of inns. As a means of literary and social improvement, Mr. W. Chambers, in 1859, made a free gift to this his native town of a spacious suite of buildings, comprising a Reading-room, a Public Library consisting of 15,000 volumes, a Museum, Gallery of Art, and Hall for lectures and concerts—the whole being designated the CHAMBERS' INSTITUTION. Long secluded from general traffic, P. has been lately opened up by railways; and the woollen manufacture has made considerable progress in the parish of Innerleithen. In 1880–81, the valued rental of the county, town included, exclusive of railway property, was £132,081; the valuation of railway property being £19,668. P. abounds in the remains of British hill-forts, Border towers, and other antiquities, and possesses numerous modern mansions of a handsome kind. Formerly, the only account of the shire was a *Description of Tweeddale*, by Dr. Alexander Pennicuk, 1715; reissued with notes, 1815; but in 1864 there was written a *History of Peeblesshire*, by W. Chambers, 1 vol. 8vo., illustrated with maps and wood-engravings.

PEEL, a small but populous and thriving seaport town on the west coast of the Isle of Man. It was formerly called 'Holm,' and was a place of great importance in the island. The herring-fishery, the building of vessels of small tonnage, and the manufacture of nets, are here carried on extensively, and form a source of large profits to the inhabitants. The bay is spacious, and abounds with fish of excellent quality.

At the northern extremity of this bay are several grotesque and romantic caverns. The southern extremity is formed by Peel Island, on which stand the grand old ruins of Peel Castle and St. German's Cathedral. The castle was formerly the frequent residence of the Earls of Derby, then Lords of the Isle of Man, and is expressly named in the original grant of Henry IV. to the Stanley family. Beneath the cathedral is a strong subterranean dungeon, where many noble persons were in former days imprisoned, including Thomas, Earl of Warwick, in the time of Richard II., and Elinor Cobham, Duchess of Gloucester, who was sentenced to perpetual imprisonment in it in the year 1440, and who died within its gloomy recesses. In Sir Walter Scott's *Peveril of the Peak*, constant mention is made of this castle, and indeed it may be said to be the scene of the story. The ruins are yearly visited and admired by thousands of persons from all parts of the United Kingdom. The town of P. is now rapidly extending its boundaries, and bids fair to become a place of considerable commercial importance. Pop. (1871) 3513.

PEEL, SIR ROBERT, a very eminent British statesman, was born, 5th February 1788, near Bury, in Lancashire. His father, Sir Robert Peel (created a baronet in 1800), was the wealthy cotton-spinner, from whom he inherited a great fortune. He was educated at Harrow, and at Christ Church, Oxford, where he graduated B.A. in 1808—taking a double first-class—and entered the House of Commons in 1809 as member for Cashel, adopting the strong Tory politics of his father. Percival was then prime-minister. P. set quietly about the business-work of the House, feeling his way with that steady prudence and persevering diligence that were the conspicuous features of his character. In 1811, he was appointed Under-secretary for the Colonies; and from 1812 to 1818, he held the office of Secretary for Ireland. In this capacity, he displayed a strong anti-Catholic spirit (whence the witty Irish gave him the nickname of 'Orange-Peel'), and was in consequence so fiercely, or, shall we say, ferociously attacked by O'Connell, that even the cool and cautious Secretary was driven to send the agitator a challenge. The police, however, prevented the duel from taking place.

From 1818 till 1822, P. remained out of office, but not out of parliament, where he sat for the university of Oxford. He now began to acquire a reputation as a financier and economist; and in 1819, was appointed chairman of the Bank Committee, and moved the resolutions which led to the resumption of cash-payments. He was still, however, as averse as ever to anything like religious or political reform. No member of the Liverpool-Castlereagh cabinet could have been to appearance more resolute. He

even vehemently defended the infamous 'Peterloo Massacre' of 1819. In 1822, he re-entered the ministry as Home Secretary—Canning shortly after becoming Foreign Secretary, on the suicide of Lord Castlereagh. The two worked together pretty well for some time, as P. devoted himself chiefly to financial matters, and especially to the currency; but 'Roman Catholic emancipation' was a question on which Canning was considerably in advance of his brother-secretary; and when the former was called upon by the king, after the resignation of Lord Liverpool, to form a sort of Whig-Tory ministry, P., along with the Duke of Wellington and others, withdrew from office. Yet it is singularly characteristic of this most honest and *compromising* statesman, that even when he seceded (1827), his opinions were veering round to the liberal and generous view of the claims of Roman Catholics; and when the death of Canning, shortly after, led to the formation of the Wellington-Peel government, its great measure—actually introduced by 'Orange-Peel' himself—was the ever-memorable one for the 'relief' of the Roman Catholics (1829).

As Home Secretary, he also signalized himself by a re-organization of the London police force—since popularly called 'Peelers' and 'Bobbies,' their previous sobriquet being 'Charles'—from King Charles I., who (1640) extended and improved the police system—and by the introduction of several other important measures.

Meanwhile, the university of Oxford had rejected its apostate representative, and chosen in his stead Sir Harry Inglis. But now came on the great question of parliamentary reform, which P. firmly but temperately opposed. In 1830, the Wellington-Peel ministry fell, and was succeeded by a Whig ministry under Earl Grey, which, in 1832, carried the Reform Bill. P. (now, by the death of his father, Sir Robert P.), when he saw that reform was inevitable, accepted defeat and its results with great equanimity. He shrank from anything like factious opposition to the measure, and contented himself with presenting as forcibly as he could the political *per contra*. After it was passed, he became the leader of the 'Conservative' opposition; and, as we have said, accepting reform itself as a *fait accompli* and irreversible, he only sought by keen and vigilant criticism of Whig measures to retard the too rapid strides of liberalism.

In 1833, when the first 'reformed' parliament assembled, P. took his seat as member for Tamworth, which he represented till the close of his life. On the retirement of the Melbourne ministry in November 1834, he accepted the office of prime-minister, but could not succeed in giving stability to his administration, and was compelled again to give place to Viscount Melbourne in April 1835, and resumed his place as leader of the opposition. P.'s conduct in opposition was always eminently patriotic. The Whigs, who were being pressed on the one side by the new Radical party and the Anti-Corn Law League, and on the other by O'Connell and the Irish repealers, gradually lost ground, and being narrowly defeated in 1841, on a motion of want of confidence, dissolved parliament. The general election that ensued was virtually a contest between Free-trade and Protection. Protection won; and when the new parliament met, a vote of no-confidence was carried by a majority of ninety-one. The Conservative party, headed by P., now came into office. The great feature of the new government was the attitude it adopted on the corn-law question. The Whigs, while in office, and even after their expulsion, were bent upon a fixed but moderate duty on foreign corn; the Anti-Corn Law League would hear of nothing short of an entire repeal, while Sir Robert was in favor of a modification of the sliding scale of duty which had existed since 1828. He introduced and carried (1842), in spite of strong opposition, a measure based upon this principle.

The deficit in the revenue, which had become quite alarming under the Melbourne administration, next engaged his attention, and led him to bring in a bill (1842) for the imposition of an 'income-tax' of 7d. in the pound, to be levied for three years. To alleviate the new burden, P. commenced a revision of the general tariff, and either abolished or lowered the duties on several very important articles of commerce, such as drugs, dye-woods, cattle, sheep, pigs, salted meat, butter, eggs, cheese, and lard. He also showed himself resolute in the repression of the clamorous and anarchic malcontents of Ireland. O'Connell (q. v.) was tried for conspiracy, and though the judgment against him was set aside on appeal to the House of Lords, the influence of the 'agitator' was broken. The first half of 1845 was marked by the allowance to Maynooth being increased and changed into a permanent endowment instead of an annual grant, and by the foundation of the Irish unsectarian colleges, and other important measures. But the potato-rot in Ireland during the autumn, followed by a frightful famine, rendered 'cheap corn' a necessity, if millions were not to starve. Cobden and the League redoubled their exertions. Lord John Russell announced the views of the Whig party on the crisis, and Peel again yielded. He told his ministerial colleagues that the corn-laws were doomed, and that their repeal was inevitable. Some of them refusing to

go along with him, he resigned; but after a few days, was recalled, and resumed office.

Lord Stanley, the late Lord Derby, seceded, and with Lord George Bentinck, Mr. Disraeli, &c., formed a 'no-surrender' Tory party; but the Duke of Wellington, Graham, Aberdeen, Gladstone, and other Conservatives, stood by him, and the measure for the repeal was carried. He was, however, immediately afterwards defeated on an Irish Protection of Life Bill. Not so much upon this account, as because he felt that the course which he had pursued had produced a dissolution of the old ties of party, and that he could not expect for some time to find himself at the head of a strong government, P. retired from office in June, 1846, giving place to a Whig administration under Lord John Russell, to which he gave an independent but general support as the leader of a middle party rather Whig than Tory. In the critical times of 1847—1849, he was one of the most important props of the government, whose free-trade principles he had now completely accepted. His ecclesiastical policy had also undergone a remarkable change, and he now frankly supported the Whigs in the efforts to carry an act for the repeal of the Jewish disabilities. He was himself regarded by the working and middle classes generally with much grateful respect. An unexpected catastrophe put an end to his career. On the 28th of June 1850, he had spoken with great eloquence in the debate on Lord Palmerston's Greek policy; but on the following day was thrown from his horse in Hyde Park, and was so much injured, that he died on the evening of the 2d of July.—He left five sons, the eldest of whom, SIR ROBERT, the second, SIR FREDERICK, and the fifth, JONATHAN, lieutenant-general in the British army, have all held office as ministers.

PEEL-TOWER (W. *pill*, a stake, a fortress; Lat. *pila*, a stake, pillar, structure), the name given to the towers erected on the Scottish borders for defence. They are square, with turrets at the angles, and the door is sometimes at a height from the ground. The lower story is usually vaulted, and formed a stable for horses, cattle, &c. For an account of these old towers, now mostly in ruin, see *History of Peeblesshire*, by W. Chambers, 1864.

PEEPUL, PIPUL, or PIPPUL (*Ficus religiosa*), also known as the SACRED FIG of India, and in Ceylon called the Bo TREE; a species of Fig (q. v.), somewhat resembling the Banyan, but the branches not rooting like those of that tree, and the leaves heart-shaped with long attenuated points. The tree is held sacred by the Hindus, because Vishnu is said to have been born under it. It is generally planted near temples, and religious devotees spend their lives under its shade. It is also held sacred by the Buddhists. It attains a great size and age. A wonderfully aged tree of this species is figured in the article Bo TREE. The P. is often planted near houses, and by the sides of walks, for the sake of its grateful shade. The juice contains caoutchouc, and is used by women as bandoline. Lac insects feed upon this tree, and much lac is obtained from it. The fruit is not much larger than a grape, and although eatable, is not valued.

PEER (Fr. *pair*; Lat. *par*, equal), a general name applied to the titled nobility of Great Britain and Ireland, indicating their equality of rank. The peerage includes the various degrees of Baron, Viscount, Earl, Marquis, and Duke. The peers of England, of Great Britain, of the United Kingdom, and certain representative peers of Scotland and Ireland, together with certain of the bishops and archbishops, who are called lords spiritual, constitute the House of Lords. The dignity of the peerage is hereditary, but in early times was territorial. Life peerages seem at one time to have been not unknown in England; but in 1856 Sir James Parke, having been created by Her Majesty Baron Wensleydale 'for and during the term of his natural life,' the House of Lords, on the report of a Committee of Privileges, held that he was not entitled to sit and vote in parliament. Ladies may be peeresses in their own right either by creation or by inheritance. The wives of peers are also styled peeresses. Under the articles NOBILITY, PARLIAMENT, DUKE, MARQUIS, EARL, VISCOUNT, and BARON, will be found notices of each order of peers, and of the origin, history, and privileges of the peers as a body.

A certain limited number of the French nobility were styled Peers of France.

PEE'WIT. See LAPWING.

PE'GANUM, a genus of plants of the natural order *Zygophyllaceae*, of which the only known species, *P. harmala*, a half-shrubby plant with linear, smooth, almost bipinnatifid leaves, and solitary white, axillary flowers, a native of the Levant and the north of India, is sometimes cultivated in gardens under the name of SYRIAN RUE. The seeds are narcotic, and the Emperor Solymán is said to have kept himself intoxicated by eating them. They were formerly used in medicine in Europe, and still are in the East. The Turks use them as a spice, and also for dyeing red.

The plant is believed to be the *Harmala* of the Greeks, mentioned by Dioscorides as one of the kinds of *Peganon*.

PEGASSE, or PACASSE (*Bos pegasus*), a species of ox, a native of the interior of Western Africa. The head is short and thick, the forehead wide; the horns long, extending laterally from the frontal ridge, then turning downwards, and again upwards; the ears very large and pendulous; the neck maned; the tail entirely covered with long hair; the legs long. Little is yet known of this curious species of a most important tribe.

PE'GASUS, in Greek Mythology, a winged horse which arose with Chrysaor from the blood of the Gorgon Medusa, when she was slain by Perseus. He is said to have received his name because he first made his appearance beside the springs (*pegai*) of Oceanus. He afterwards ascended to heaven, and was believed to carry the thunder and lightning of Zeus. According to later authors, however, he was the horse of Eos. The myth concerning P. is interwoven with that of the victory of Bellerophon over Chimæra. Bellerophon had in vain sought to catch P. for his combat with this monster, but was advised by the seer Polydorus of Corinth to sleep in the temple of Minerva, and the goddess appearing to him in his sleep, gave him a golden bridle and certain instructions, upon which he acted, and made use of P. in his combat with the Chimæra, the Amazons, and the Solymi. P. is also spoken of in modern times as the horse of the Muses, which, however, he was not. The ancient legend on this subject is, that the nine Muses and the nine daughters of Pieros engaged in a competition in singing by Helicon, and everything was motionless to hear their song, save Helicon, which rose ever higher and higher in its delight, when P. put a stop to this with a kick of his hoof, and from the print arose Hippocrene, the inspiring spring of the Muses. But that P. is the horse of the Muses, is entirely a modern idea, being first found in the *Orlando Innamorato* of Boiardo.

PEGASUS, a genus of fishes, constituting the family *Pegasiidae*, of the order *Lophobranchii* (q. v.) The species are few; they are small fishes, natives of the Indian seas, interesting from their peculiar form and appearance.

Sea Dragon (*Pegasus draco*).

The breast is greatly expanded, much broader than high, the gill-openings in the sides; the pectoral fins are extremely large and strong; a long snout projects before the eyes, and the mouth is situated under and at the base of it; the body is surrounded by three knobbed or spinous rings. One species (*P. draco*) is called the SEA DRAGON, another (*P. volans*) is popularly known as the PEGASUS.

PEGS. Small square pointed pegs of wood have of late years been introduced by the Americans into the manufacture of boots and shoes, for the purpose of connecting the parts of the sole and upper leather together without sewing. See SHOEMAKING. This invention has been so extensively adopted, that the manufacture of wooden pegs, for this purpose, has become an important trade in America and Bohemia, from which countries a considerable importation is made to Great Britain. They are chiefly made of maple-wood, and are rarely more than an inch in length.

PEGU', in British Burmah, was till lately the central division, lying between Aracan in the north, and Tenasserim in the south; and comprised the valley of the Lower Irrawadi and the coast. In this sense it had, in 1872, an area of 26,979 sq. miles, and a pop. of 1,662,058. At the census of 1881, however, it had been severed into two divisions, P. and Irrawadi, with other minor readjustments. P., containing the districts of Rangoon town, Hantawadi, Tharrawadi, and Prome, had, in 1881, an area of only 9159 sq. m., and a pop. of 1,162,398. The new division, Irrawadi, had an area of 16,805 sq. m., distributed into the districts of Thun-khwa, Bassein, Henzada, and Thayetmyo, and a pop. of 1,161,119. Of the joint population of the two divisions, about 800,000 are true Burmans; but in addition to these, there is a sprinkling of Karens, who live in the wild and hilly districts, Taleins or Pegu-gers, Shans, Khyengs, Yabaings, Indians, Chinese, and a few other races.

The principal river of P. is the Irrawadi (q. v.). In March, the river begins to rise, and gradually increases in volume till its waters are forty feet above their lowest level. They rapidly subside in October, when the rains cease, and the north-east monsoon

sets in. Other rivers are the Hlaing or Rangoon, the Pegu, the Sittaung, and the Bhaling. P. was annexed to British India at the close of the Burman war of 1852, since which time slavery has ceased to exist, schools have been established, and various public works undertaken. Rice and teak timber are the principal exports. A flotilla of steamers keeps up the communication between Rangoon (q. v.), the principal port, and the chief stations on the Irrawadi, conveying troops, stores, passengers, and mails from place to place.

P. is also the name of the north-east 'township' of the Rangoon district, containing the headquarters town of P. The north-western portion is mountainous and forest clad; towards the south the hills sink towards the fertile level land, covered with rice fields. The Pegu River, 180 miles long, intersects the township, and finally joins the Rangoon River.

P. town, on the river, now but a small place of some 5000 inhabitants, seems by the accounts of European travelers in the 18th c., to have been of great size and magnificence, strongly fortified. The ancient town was founded in 573 A.D.; and its sovereigns reigned over the Irrawadi, conquered Ava, and successfully invaded Siam and Aracan.

PEHLEVI (Valor, Power; *Zabân Pehlevi* = Language of Heroes) is the name of an ancient West-Iranian (Median and Persian) idiom, in use chiefly during the period of the Sassanides (235–640 A.D.), who, wishing fully to restore the ancient Persian empire, endeavored also to reinstate the primitive national language, fallen into disuse as a court-language since the time of Alexander's conquest. Yet they did not fix upon the pure Persian as it was still spoken in the interior, but upon the dialect of the western provinces, largely mixed with Semitic words, to which Arian terminations were affixed.

The grammatical structure of the P. presents almost the same poverty of inflections and terminations as the present Persian. Although, however, less rich than Zend (q. v.) in inflection and accentuation, it yet boasts of the same copiousness of words as that dialect, to which it in reality succeeded. It is written from right to left, and the letters are mostly joined. The remnants of P. extant consist of coins, inscriptions (found at Hajarabad, Persepolis, Kirmanshah, &c.), and a number of books, all relating to the religion of Zoroaster. The most important of these are the translation of the chief part of the Zend-Avesta (Yazna, Visparad, and Vendidad), and such original religious works as the Bundehehsh, Shikandgumân, Dinkhart, Atash Barâm, &c. The P. of the books differs from that of the inscriptions and coins to such a degree—according to the larger or smaller preponderance of the Semitic element—as to have misled investigators (Westergaard and others) to assume that two utterly distinct languages, a purely Iranic and a Semitic one, had been used somewhat indiscriminately at the time. The non-Iranian element is called Huzvareh (Huzoresh) by the Parsee priests, who taking advantage of the ambiguity of the P. alphabet, often substitute the corresponding Persian for the foreign words. The Iranian part of the P. differs little from the Persian of our own day, and, in fact the P. changed first into Parsee, and subsequently into modern Persian, simply by getting rid first of its Chaldee, and then of those of its Iranian words which had become obsolete. The chief use of the P. dialect at present is the assistance it offers towards the education of the Zend itself. For the history of its investigation since it was first made known in Europe, we refer to PERSIAN LANGUAGE AND LITERATURE.

PEI-HO', a river of China, which, rising on the confines of Tartary, traverses the northern part of the province of Chih-le (q. v.) or Pe-chih-le, and falls into the Gulf of Pe-chih-le, in about 38° 30' N. lat.

The attack on the escort of the British and French ambassadors, whilst ascending the Pei-ho to Peking in June 1859, led to the war with China of 1860. See CHINA.

PEINE FORTE ET DURE, the 'strong and hard pain;' a species of torture formerly applied by the law of England to those who, on being arraigned for felony, refused to plead, and stood mute, or who peremptorily challenged more than twenty jurors, which was considered a contumacy equivalent to standing mute. In the beginning of the 18th c., this penalty seems to have consisted merely in a severe imprisonment with low diet, persisted in till the contumacy was overcome. But by the reign of Henry IV., it had become the practice to load the offender with weights, and thus press him to death; and till nearly the middle of the 18th c., pressing to death was the regular and lawful mode of punishing persons who stood mute on their arraignment for felony. The motive which induced an accused party, in any case, to submit to this penalty rather than to plead, was probably to escape the attainder which would have resulted from a conviction for felony. During the 15th, 16th, 17th, and even the 18th c., various cases are recorded of the infliction of the punishment in question. Lastly, a practice prevailed which had no sanction from the law, of

first trying the effect of tying the thumbs tightly together with whiplcord, that the pain might induce the offender to plead.

Among instances of the infliction of the *peine forte et dure*, are the following: Juliana Quick, in 1442, charged with high treason in speaking contemptuously of Henry VI., was pressed to death. Anthony Arrowsmith, in 1598, was pressed to death (Surtees' *History of Durham*, vol. 8, p. 271). Walter Calverly of Calverly, in Yorkshire, arraigned at the York assizes in 1605, for murdering his two children and stabbing his wife, was pressed to death in the castle by a large iron weight placed on his breast (Stow's *Chronicle*). Major Strangways suffered death in a similar way in Newgate in 1657, for refusing to plead when charged with the murder of his brother-in-law, Mr. Fussell. In 1720, a person of the name of Phillips was pressed in Newgate for a considerable time, till he was released on his submission; and the same is recorded in the following year of one Nathaniel Hawes, who lay under a weight of 250 lbs. for seven minutes. As late as 1741, a person is said to have been pressed to death at the Cambridge assizes, the tying of his thumbs having been first tried without effect.

The statute 12 Geo. III. c. 20 virtually abolished the *peine forte et dure*, by enacting that any person who shall stand mute when arraigned for felony or piracy shall be convicted, and have the same judgment and execution awarded against him as if he had been convicted by verdict of confession.

PEI'PUS, LAKE, in the north-west of Russia, is surrounded by the government of St. Petersburg, and the provinces of Esthonia and Livonia. On the south-east it is connected with Lake Pskoff by a strait 16 miles in length and from $1\frac{1}{2}$ to $4\frac{1}{2}$ miles broad. The length of both lakes is 87 miles, the greatest breadth about 40, and the depth from 14 to 49 feet. Lake Pskoff receives the waters of the river Velekaia, and Lake P. is supplied by Lake Pskoff, and by the Embach from the west, and other rivers. The waters of the lower lake are carried to the Gulf of Finland by the Narova. The lakes are studded with several picturesque islands, and surrounded with banks which are for the most part marshy and abound in fish, the taking of which gives employment to many.

PEI'SHWA (Minister) was the title of the personage third in rank and authority at the court of the Mahratta Maharajahs of Satara, there being only the *Priti-nidhi* (Delegate of the Rajah) between him and his sovereign. However, during the weak reigns of Sevajee's descendants, the minister increased in importance, till, at the commencement of the 18th c., BALAJEE BISWANATH, the then Peishwa, and a man of distinguished administrative ability and diplomatic talents, made himself virtually the ruler of the Mahrattas (q. v.).

PEISI'STRATOS (Lat. *Pisistratus*), a famous 'tyrant' of Athens, belonged to a family of Attica, which claimed descent from Pylon Nestor, and was born towards the close of the 7th c. B.C.—certainly not later than 612. His father's name was Hippocrates, and through his mother he was pretty closely related to the great lawgiver, Solon, between whom and P. a very intimate friendship long existed. He received an excellent education; and the charm of his manners, as well as the generosity of his spirit was so great that (according to Solon) had he not been ambitious, he would have been the best of Athenians; but his passion for the exercise of sovereign power led him to adopt a policy of artifice and dissimulation, for the purpose of attaining his ends, which prevents us from regarding him with the admiration that the beneficent character of his government might seem to demand. At first, P. co-operated with his kinsman Solon, and in the war against the Megarians, acquired considerable military distinction; but afterwards, when probably his ambitious views had become more matured, he came forward as the leader of one of the three parties into which Attica was then divided. These were, the *Peidaii* (party of the Plain), or the landed proprietors; the *Parali* (party of the Seaboard), or wealthy merchant classes; and the *Diacrii* (party of the Highlands), chiefly a laboring population, jealous of the rich, and eager for equality of political privileges. It was to the last of these that P. attached himself; but indeed he assiduously cultivated the good-will of all the poorer citizens, to whom he showed himself a most liberal benefactor. At last P. took a decided step.

Driving into the market-place of Athens one day, and exhibiting certain self-inflicted wounds, he called upon the people to protect him against his and their enemies, alleging that he had been attacked on account of his patriotism. Solon, who was present, accused him of hypocrisy; but the crowd were, according to Plutarch, ready to take up arms for their favorite; and a general assembly of the citizens being summoned, Ariston, one of P.'s partisans, proposed to allow him a body-guard of fifty men. The measure was carried in spite of the strenuous opposition of Solon. Gradually P. increased the number, and in 560 B.C., when he felt himself strong enough, seized the Akropolis. The citizens, in general, seem to have tacitly sanctioned this high-handed act. They were sick of the anarchic broils of the differ-

ent factions, and probably glad to see their champion and favorite usurp supreme authority. Megakles and the Alkmaeonids—the heads of the rich aristocratic party—immediately fled from the city. Solon, who loved neither oligarchic arrogance nor military despotism, but was a thorough constitutionalist, tried, but in vain, to rouse the Athenians against Peisistratos. P., who was not at all vindictive in his disposition, did not attempt to molest Solon; he even maintained the legislation of the latter almost intact, and distinguished himself chiefly by the vigor of his administration. P. himself did not enjoy his first 'tyranny' long.

The *Pediosi* and the *Parali* rallied under Lykurgos and Megakles, united their forces, and overthrew the usurper, who was forced to go into exile. But the coalition of the two factions was soon broken up. Megakles hereupon made overtures to P., inviting him to resume his tyranny, which he did, but a family quarrel with Megakles induced the latter to again ally himself with Lykurgos, and P. was driven from Attica. He retired to Eubœa, where he remained for ten years, ever keeping an eye, however, on Athens, and making preparations for a forcible return. How he managed to acquire so much influence while only a banished man, is difficult to ascertain; but certain it is that many Greek cities, particularly Thebes and Argos, placed the greatest confidence in him, and finally supplied him abundantly with money and troops. P. at length sailed from Eubœa, landed in Attica at Marathon, and marched on the capital. His partisans hurried to swell his ranks. At Pallene, he encountered his opponents, and completely defeated them, but used his victory with admirable moderation. When he entered the city, no further resistance was made, and he resumed the sovereignty at once. The date of this event, as of most others in the life of P., is very uncertain; perhaps we shall not err far if we place it about 545 B.C. He lived for sixteen years afterwards in undisturbed possession of power, dying 527 B.C., and transmitting his supremacy to his sons, Hippias and Hipparchus, known as the *Peisistratids*. His rule was mild and beneficent.

Although the precautionary measures that he adopted to establish his authority involved at first a certain resolute and stringent policy (e. g., the seizure of the children of his leading opponents, and the detaining them as hostages); yet no sooner had he placed himself out of danger, than he began to display that wonderful tact, moderation, kindness, and sympathetic appreciation of the wishes of the Athenians, that have won him the praise and esteem of all later ages, in spite of his usurpation. He firmly, but not harshly, enforced obedience to the laws of Solon; emptied the city of its poorest citizens, and made them agriculturists, supplying such as had no resources with cattle and seed; secured provision for old and disabled soldiers; bestowed great care on the celebration of the religious festivals of the Atticans, and even introduced some important changes; encouraged literature more than any Athenian had ever done before—it is to P., or to the poets, scholars, and priests about him, that we owe, for example, the first complete edition of Homer (q. v.); and, like his still more brilliant successor in the following century, Perikles, he adorned Athens with many beautiful buildings, such as the Lyceum, a temple to the Pythian Apollo, another to Olympian Zeus, &c.

PEKAN, or WOOD-SHOCK (*Martes Canadensis*), a species of Marten (q. v.), very nearly allied to the sable, a native of the northern parts of North America. It is twice the size of the pine marten, and is generally of a grayish brown color; the legs, tail, and back of the neck marked with darker brown. The fur, although not so valuable as sable, nor even as that of the pine marten, is useful, and large quantities are sent to the market. The P. lives in burrows, which it excavates in the banks of rivers; and feeds chiefly on fish and other aquatic animals.

PEKI'N, or PE-KI'NG (i. e., Northern Capital), the capital of the Chinese empire since 1421 A.D., is situated on a sandy plain about 18 miles north-west of the Peiho, in lat. 39° 54' 13" N., and long. 116° 28' 54" E., in the northern province of Chih-le, at a distance of nearly 100 miles from the sea, and about 60 miles from the great Chinese wall. The pop. of the city is estimated at about 2,000,000; and the circuit of the walls, according to the latest measurements, is 20 miles. These walls are made of earth, with an outer casing of brick, having embrasures for musketry or ordnance every 50 feet. Those of the Tartar city have an average height of 50, but in some places of 61 feet. In thickness they vary from 57 to 22 feet. The walls of the Chinese city are only 30 feet in height, and from 15 to 25 in width. The top, to which horsemen can ascend by a ramp or sloping way, is paved with stone. At intervals of 60 yards are square towers or buttresses, projecting outwards from the walls 50 or 60 feet. The gates which give access to the city from the surrounding country are 16 in number, nine of which belong to the Northern or Tartar City, and seven to the Southern or Chinese City. Over each gate is a watch-tower nine stories in height, and loop-holed for cannon.

The city of P. is divided into two parts, separated by a wall with three gates. These two sections form respectively the

Northern, Interior, or Tartar City, called *Nei-tching* ('within the walls'); and the Southern, Exterior, or Chinese City, called *Wai-tching** ('without the walls'). 'Tching' or 'ching,' it may be remarked, means both city and wall.

1. *Nei-tching, or the Northern City*, has three distinct divisions or enclosures—viz., Kin-tching, or the Prohibited City; the Hwang-tching, or Imperial City; and the General City. The first of these—the innermost or central block—is surrounded by a red brick wall about two miles in circumference, which shuts in the palaces, pleasure-grounds, and temples of the sacred city. Here live the emperor and his family, the ladies of the court, and the attendant eunuchs. The palace proper consists of four large and two small buildings, called the Tching-kung, or 'the Palace,' the Tung-kung, Sikung, and Kin-luan-teen. The smaller buildings are allotted to the dowager-empress and suite; they are called the Ning-shou-kung, and the Keen-ting-kung, or the 'Palace of Earth's Repose.' Other notable buildings of the Prohibited City are Fung-seen-teen, the 'Temple of Imperial Ancestors,' Tching-hwang-meou, the 'Guardian Temple of the city,' Nan-heun-teen, 'the Hall of Portraits of the Chinese emperors and sages,' and Wan-yuen Ko, the 'Hall of the Literary Abyss' i. e., the Imperial Library. It also contains the offices of the cabinet, in which the members hold their sessions, the imperial treasury, the court of controllers for the regulation of the receipts and expenses of the court, &c.—The Imperial City is built around this central block, and contains the palaces of the princes, temples, some of the government offices, and spacious pleasure-grounds, with beautiful artificial lakes.

From Woo-ying-teen, the imperial printing-office, the *Imperial, or Pe-king Gazette* is issued daily for all government officials throughout the empire. This is the only publication in China approaching to a newspaper, and is named *King Paou*, or 'Great Report.' It is not merely a report for official information, but forms the basis of the national annals, and is compiled from the daily records of the Supreme Council. Besides the daily edition, there is one published every two days, which is sold to the public, and from which is withheld decrees and reports of a secret character. The journal itself is a miserable production even for China, and consists of from 15 to 20 pages not so large as common newspaper.—The General City—the third division or enclosure—lies between the Imperial City and the outside walls; it is more densely populated than either of the preceding divisions, and contains the most important of the public offices, including the six supreme tribunals or boards—the Le-fan-yuen, or the Office of Foreign Affairs; Too-cha-yuen, or the Imperial Censorate, &c.; Han-lin-yuen, or the Grand National College; the Great Medical College; the Observatory; the Examination Hall, with—it is said—ten thousand cells for the candidates who assemble to compete for public offices; and the British, French, Russian, and United States legations. One may also notice the Lama temple, founded 1725–30 to conciliate the Tibetan priesthood; the temple of Confucius, in which the emperor solemnly 'worships' the great sage once a year; and the Mohammedan mosque. The British minister resides in the Leang-kung-foo, or the Palace of Leang, a gorgeous building, consisting of four or five large halls, and covering about five acres of land. The principal streets of the general city—from 140 to 200 feet wide, and unpaved—are continuous lines of shops painted red, blue, and green, decorated with staring signs, and resplendent with Chinese characters highly gilt.

By day and night, by the light of the sun, or by the illumination of torches and paper lanterns, the roar of these great thoroughfares is incessant; shopkeepers, pedlers, mountebanks, quack-doctors, passengers on foot or on horseback, each and all contributing to the general hubbub. The minor streets and lanes, where the houses of the populace are mingled with public offices, temples, stores, and manufactories, are by no means pleasant places, their general characteristics being an 'insupportable odor,' and one-storied brick houses with roofs of a gray color. There is 'Fetid Hide Street,' 'Dog's-tooth Street,' 'Dog's-tail Street,' 'Barbarian Street,' and many others with names equally uninviting.

2. *Wai-tching, or the Southern City*, the second great division of P., contains most of the mercantile population of the capital, but does not present many features of interest to the traveler. Teen-Tan, or the temple to Heaven, and Tee-Tan, or the temple to Earth, with their grounds occupy a considerable space. The latter is considered a sort of temple of agriculture, and its grounds, are the scene of the well-known ceremony in which the emperor, assisted by members of the Board of Rites, opens the plowing-season in China at the vernal equinox. The theaters and places of public amusement are likewise situated in the Southern or

* Northern City and Southern City are the most correct terms. The latter was added to the more ancient Northern City, and was originally designed to encircle it; hence it was called the Exterior City, in contradistinction to the Northern or Interior City. It was also intended to reserve the Northern City for the Tartars, and the Southern City for the Chinese, as the names still imply; but in point of fact, the Tartar City contains as many Chinese as Tartars; and it is not surrounded by the so-called Chinese City, which latter has only been added on the south side.

Chinese city; also the Golden Fish-ponds, and the execution-ground.

Outside the city, there are unwall'd suburbs, as about every walled town in China. These are of considerable extent, but straggling, and consist principally of an agricultural population, the land being everywhere in a state of cultivation, producing chiefly maize and millet, as it is not so suitable for the staple products of rice and wheat. The land is badly watered but well timbered, which gives a pleasing aspect to the landscape; and when viewed towards the range of mountains extending from the west of P. to the north-east, presents a picturesque panorama. About 8 miles north-west of P., the famous *Yuen-ming-yuen* (lit. 'Round and Splendid Gardens') palaces are situated, which were sacked and destroyed by the allies in October 1860. These were 30 in number, surrounded by every variety of hill and dale, woodland and lawn, interspersed with canals, pools, rivulets, and lakes, with numerous temples and pagodas containing statues of men and gods in gold, silver, and bronze. Here had been heaped up for centuries all the movable riches and presents of the emperors of China, amongst which were found many sent by the English embassies. At the approach of the allies, Hien-fung fled in haste; and when Lord Elgin learned that it was in those grounds that the British and French prisoners, captured by treachery, had been tortured, he gave the order to sack and destroy this favorite residence of the emperor's, 'as it could not fail to be a blow to his pride as well as his feelings; and it became a solemn act of retribution.' The palaces were cleared of every valuable, and their walls destroyed by fire and sword.

P. has thus been rendered memorable by this march of the British and French forces (1860) to the walls of the city, on which the British and French flags were raised. The provisions of the treaty of Tien-tsin 1858, (see CHINA), were subsequently ratified and supplemented by the *Convention of P.*, which was signed in the English and French languages at P., October 24, 1860. The most important article of this Convention is that which allows the residence of a British envoy at P., a privilege formerly enjoyed by Russia alone. The greatest benefits have resulted to both governments by this step. The same privilege has been granted to the French and American governments. Foreigners of all nations are allowed to visit, but not to trade within the precincts of the city.

P. is a very ancient city. Centuries before the Christian era, it was the capital of the kingdom of *Yen*, but when this kingdom was overthrown by the *Tsin* dynasty in 222 B.C., the seat of government was removed elsewhere. About 938 A.D., it again became the capital of the *Kitan* dynasty. In 1215 it was captured by Genghis Khan; and in 1264, Kublai Khan (whom readers of Coleridge will remember) fixed his residence here. The native emperors, however, who succeeded the Mongol dynasty, removed the court to Nanking, which was reckoned the chief city of the empire till Yang Lo, the third emperor of the Ming dynasty, in 1421, once more made it the imperial residence, which it has ever since remained.—See *Yedo and Peking*, by Fortune (1863), Renne's *Peking and the Pekingese* (1865), Lord Elgin's *Despatches* (1860), and the various recent books on China, noted at the end of the article CHINESE EMPIRE.

PELAGIANISM, the doctrinal system of Pelagius (q. v.), especially on the subjects of the natural condition of man, original sin, grace, free-will, and redemption. Under the head PELAGIUS will be found what may be called the external history of the controversy to which the opinions of that remarkable man gave occasion. The movement, considered in itself, is one of the most interesting in the history of the human mind. At the close of the great controversies on the Trinity and Incarnation, the speculation, which for nearly a century had wearied itself in vain endeavors to make plain the inscrutable mysteries of the divine nature, at length turned inwards upon itself; and no one at all familiar with the controversy on P. can doubt that that prouder view of the capabilities of human nature, which lies at the root of all the theories of which P. was but the exponent, was a reaction against the crude and degrading conceptions of the nature and origin of the soul which characterized the philosophy, not alone of the Manichaean teachers, but of all the dualistic religions which sprung from the prolific soil of Gnosticism. To the Manichæan, and to all in general who adopted the Gnostic views as to the evil origin and nature of matter and material substances, man was, in his *psychical* nature, evil and incapable of good.

The Christian teacher, in combating this view, easily passed into an opposite extreme, and overlooking or explaining away the strong language of the Scripture, was led to represent man as endowed with full capacity for all good; and so long as the only adversaries to be controverted were those who urged the views of the Gnostic school, the line taken by Christian writers was but little guarded by any of those limitations and reserves which have arisen in later controversy; and thus the earlier Fathers, especially those of the Eastern Church, where Gnosticism was chiefly to be

combated, are found to press earnestly the power for good which man possesses, without entering nicely into the origin or the motive principle of that power. But whatever of vagueness hung over this important subject was dispelled by the bold and precise statements of Pelagius, or at least by the discussion which at once arose thereupon, throughout the entire church. His teaching on the subject of original sin and on the primitive state of man, has been already detailed. See ORIGINAL SIN. The earliest formal embodiment of these doctrines, for the purpose of obtaining upon them the public judgment of the church, was in a number of articles presented to the council of Jerusalem, in 415, by Orosius. See PELAGIUS. Of these, the first five regarded the doctrines already noticed under ORIGINAL SIN. The latter portion of the articles alleged that no grace or aid from God was needed for particular actions, but that free-will and the teaching of the law sufficed; that God's grace is given in proportion to our merits; that free-will would not be free, if it stood in need of aid from God; that the pardon of penitents is not granted according to God's grace and mercy, but according to their own merit and labor; and that our victory does not come from God's assistance, but from our free-will. Although the final sentence condemnatory of these doctrines (see PELAGIUS) was very generally accepted, yet the recusant party was not wanting in energy and ability.

The great champions on each side were Augustine for the orthodox, and Julianus, Bishop of Eclanum for the Pelagians. Of so much of the controversy as regards original sin, the history has been already related; that on grace and free-will was more subtle, and has led to more numerous divisions on the side of orthodoxy as well as of dissent. In order to evade the condemnation of the doctrine originally ascribed to them as to grace, Pelagius and his followers declared that they did not deny the necessity of grace; but by this name they did not understand any real and internal supernatural aid given by God in each particular action, but only either some general external assistance, such as preaching, the Scriptures, good example, &c., or an aid given which might facilitate and secure the particular work, but which was by no means necessary for its accomplishment. Whether, indeed, they at any time admitted any real internal grace, is a question much disputed. Grace is of two kinds—that which moves the will, and that which enlightens the understanding. It is necessary, too, to distinguish two periods in the history of P.—one before the appearance of the *Epistola Tractoria* of Pope Zosimus; the other, subsequent to that decree. In the first period, it would seem that the Pelagians did not admit the necessity of any internal grace whatever; in the latter, they admitted the necessity of a grace of the intellect, but not of the will; or if they seemed to speak of any internal grace of the will, it was only as facilitating man's act, not as at all necessary to his doing it.

The Pelagian theory, in a word, was that man, as coming from his Creator's hand, possessed in himself, and as constituents of his own nature, all the powers which are necessary for the attainment of salvation; that by the faithful employment of these natural powers, without any further aid whatever from God, he merits eternal life, and all other rewards, by a strict title of justice; and that, to suppose grace to be necessary, is in truth to destroy the essence of free-will. This doctrine was somewhat modified in the Semi-Pelagian System (q. v.). The Catholic schools, all without exception, maintain the necessity of grace for the performance, not only of all meritorious, but of all supernatural good works; and they are equally unanimous in maintaining that the grace so given, even that which is called 'efficacious,' does not destroy the freedom of the will. They distinguish between the 'natural' and the 'supernatural' order, and between the powers and gifts which are proper to the one and to the other. For the attainment of all the ends of the natural order, man possesses, by his very constitution, all the powers and all the gifts which are necessary; and by the proper use of these powers, he is able to merit all the rewards which belong to the natural order. He is able, therefore, without any supernatural grace, to perform morally good works (as acts of natural benevolence, the fulfilment of the ordinary duties to his neighbor, &c.), and to fulfil the purely natural obligations. But in order to works in the supernatural order (such as the love of God above all things for His own sake, faith in Him as the author of all good, &c.), and the rewards which are promised for such works, the will of man must be moved and strengthened by supernatural grace, with which the will freely co-operates, but which is a purely gratuitous gift of God—so purely gratuitous, that although God has promised eternal life as the reward of man's co-operation, yet the merit arises entirely from God's gift and promise, and not from the natural powers of the human will.

Without going into the details of the teaching of the Catholic schools, it will be enough to particularize the most remarkable among them. Of these, the chief are the Molinist, which, giving most to liberty, lies nearest to the border of P., but is clearly distinguished from it by maintaining the necessity of grace for every supernatural act; and the Thomist and Augustinian, which give

most to grace, but at the same time expressly preserve the freedom of man's will. The Thomists are often represented as denying the freedom of man's actions under grace; but although it is difficult to explain, in popular language, their method of reconciling both, yet, to those acquainted with the scholastic terminology, their distinction between the infallible efficaciousness of grace, and its imposing necessity on the will, is perfectly appreciable. In this they, as well as the Augustinian school, differ from the Jansenists (q. v.). The Jansenists, indeed, regard the Molinist school as a plain revival of P., and they profess that they alone represent fully, in their own system, the very same position which St. Augustine formerly maintained against that heresy in its first origin.

In the Reformed Church, the Arminian doctrine may be said to correspond in the main with the Molinist system in the Roman Church. The Gomarists, in most, although not in all particulars, fall in with the Jansenistic views. The Pelagian views are distinctly represented in modern controversy by the Socinians and Rationalists; and indeed very many of those who, outside of the Roman Church, have at various times engaged in the predestinarian controversy on the side of free-will, have leaned towards, if they have not fully adopted, the Pelagian view. In this controversy, however, the practice, which is not uncommon in polemics, of imputing to an antagonist the extreme views of the particular side to which he leans, has been specially noticeable. The Jesuits have been stigmatized, even by their Catholic antagonists, as Pelagians; the Thomists are called by the Jesuits indiscriminately Jansenists and Calvinists; while both unite in representing Calvin and his school as in substance Manichæan.

Hardly one among the many Christian controversies has called forth a greater amount of subtlety and power, and not one has so long and so persistently maintained its vitality. Within the twenty-five years which followed its first appearance, upwards of thirty councils (one of them, the General Council of Ephesus) were held for the purpose of this discussion. It lay at the bottom of all the intellectual activity of the conflicts in the mediæval philosophic schools; and there is hardly a single subject which has come into discussion under so many different forms in modern controversy. See JANSEN, ARMINIUS, GRACE, PREDESTINATION, REPROBATION, ORIGINAL SIN, TRADUCIANISM.

PELAGIUS, a celebrated heresiarch of the 5th c., author or systematizer of the doctrine known as PELAGIANISM (q. v.). Of his early life, little is known. He was probably born about or before the middle of the 4th c., in Britain, or according to some, in Bretagne, his name being supposed to be a Greek rendering (*Pelagios*, or of belonging to the sea) of the Celtic appellation *Morgan*, or sea-born. He was a monk, but the time and place of his entering that state are unknown; it is certain, however, that he never entered into holy orders. He settled in Rome, and at the end of the 4th c., he had already acquired a considerable reputation for sanctity and for knowledge of the Holy Scriptures and the spiritual life. P. does not appear to have himself been a very active propagandist; but he had attached to his views a follower of great energy, and a bold and ardent temper, named Celestius, who is generally supposed to have been a Scot, which, in the vocabulary of that age, means a native of Ireland. At Rome, however, they attracted but little notice, although they began to make their doctrine public about 405; and in 410, after the sack of the city by the Goths, they withdrew to Africa. After some time, P. made a pilgrimage to Jerusalem, where he met St. Jerome, and for a time enjoyed the regard and confidence of that eminent but hot-tempered scholar. His opinions, however, becoming known, Jerome withdrew from this association.

Celestius having remained at Carthage, and sought to be admitted to ordination, his doctrines became the subject of discussion, and in a synod several opinions ascribed to him were condemned. He appealed to Rome, but leaving Carthage without prosecuting the appeal, he passed to Ephesus; and the proceedings taken in Carthage regarding him are chiefly important as having first introduced St. Augustine into the controversy. Meanwhile P. remained at Jerusalem, and news of the proceedings at Carthage having been carried to Palestine, P., in 415, was accused of heresy before the synod of Jerusalem, by a Spaniard named Orosius. The impeachment failed, probably from the fact that Orosius was unable to speak Greek, the language of the synod; and in a synod subsequently held at Diospolis in the same year, P. evaded condemnation by accepting the decrees of the synod of Carthage already referred to, and even obtained from the synod an acknowledgment of his orthodoxy. The West, however, was more sharp-sighted or less indulgent. A synod of Carthage, in 416, condemned P. and Celestius, and wrote to Pope Innocent I., requesting his approval of the sentence, with which request Innocent complied by a letter which is still extant. On the death of Innocent, Celestius came to Rome in person, and P. at the same time addressed a letter to Zosimus, the successor of Innocent; and in a council which Zosimus held, Celestius gave such explana-

tions that the pope was led to believe that the doctrines of P. had been misunderstood, and wrote to call the African bishops to Rome.

A council of 214 bishops, however, was held in Carthage, in which the doctrines of P. were formally condemned in nine canons, which were sent to Rome with full explanations; and on receipt of these decrees, Zosimus re-opened the cause, cited and condemned Celestius and P., and published a decree, called *Epistola Tractoria*, adopting the canons of the African council, and requiring that all bishops should subscribe them, under pain of deposition. Nineteen Italian bishops refused to accept these canons, and were deposed. Their leader, and the person who may be regarded as the greatest theological advocate of P. in the ancient controversy, was the celebrated Julian, bishop of Eclanum, near Beneventum, who is well known to every reader of his great antagonist, St. Augustine. P. himself was banished from Rome, in 418, by the emperor Honorius. From this date P. disappears. Of his after-life, nothing is known in detail. Orosius gives an unfavorable account of his later career, but in a period of such excitement, we may not accept implicitly the judgment of an adversary. The controversy, considered as an exercise of intellectual energy, is the most remarkable in the ancient history of the church. But the most important of the writings on the Pelagian side have been lost. Julian is chiefly known through the replies of Augustine.

P.'s *Fourteen Books of a Commentary on St. Paul's Epistles*, his *Epistle to Demetrius*, and his *Memorial to Pope Innocent*, have escaped destruction probably from their being included by collectors in the works of St. Jerome. They are much mutilated, but yet almost certainly genuine. All his other works have been lost, except some further portions, chiefly fragmentary, which (with the above) have been published under the title of *Appendix Augustiniana*. After his banishment, P. is supposed to have returned to his native country, and to have died there. Others, however, represent him as having died in Palestine. Of his doctrines in detail, an account will be found under PELAGIANISM.

PELARGONIC ACID ($\text{HO}, \text{C}_{15}\text{H}_{31}\text{O}_2$) is one of the volatile fatty acids of the general formula $\text{C}_n\text{H}_{2n}\text{O}_2$. It is an oily fluid, nearly insoluble in water, but soluble in alcohol and ether. It derives its name from its having been originally obtained from the leaves of *Pelargonium roseum* (see next article), by distilling them with water. It may also be obtained by the oxidation of oleic acid or of oil of rue by nitric acid. The pelargonate of oxide of ethyl, $\text{C}_2\text{H}_5\text{O}, \text{C}_{15}\text{H}_{31}\text{O}_2$, is an oily fluid of a very peculiar smell. According to Frankland, it is to this compound that old whisky owes its peculiar flavor; and its addition to new whisky, with a view of giving it an old flavor, is not uncommon.

PELARGONIUM, a genus of plants of the natural order *Geraniaceæ*, including many of the most favorite greenhouse flowers, to which the old generic name, *Geranium*, is often popularly given. The characters which distinguish P. from geranium, as now restricted by botanists, are given in the article GERANIUM. The species are numerous, and mostly South African; Australia also producing a few. Some of them are herbaceous, and some of them are stemless; most of them are half-shrubby. Some have tuberous root-stocks. The leaves exhibit great variety in form, division, &c. The flowers always adhere to a certain type in form, but with great variety in size, color, &c.; they are always in stalked umbels, which arise from the axils of the leaves or in the stemless kinds from the midst of the leaves. In no genus has the art of the gardener produced more striking results than in this; and the number of beautiful hybrids and varieties is very great, some of them excelling in beauty any of the original species. Some species, not possessing much beauty of flower, are cultivated for the grateful odor of their leaves, which in some resembles that of roses; in others, that of apples, lemons, &c.; whilst that of many species is rather unpleasant. The cultivation of Pelargoniums is similar to that of other *Geraniaceæ*. See GERANIUM. A few of the species endure the open air in the south of England; many are planted out in summer even in Scotland. Water must be liberally supplied to pelargoniums during the time of flowering; but no plants more strongly require a period of rest, and water must then be very sparingly given. Many of the shrubby kinds may be taken out of the soil, hung up by the roots in a dry dark cellar, or covered with hay, and put aside in a box, in a cool dry loft or garret, care being taken however, to protect them from frost. Every leaf should be removed before they are taken up, and young watery shoots should be cut off.

Another method of treating them is to cut every leaf before frost comes, and to keep the plants all winter in their pots in a dry cool room, without giving them a drop of water. By such means, many of this beautiful genus are successfully cultivated by persons who have no greenhouse.

PELAGIANS, variously explained as denoting either 'Swart-thy Asiatics,' (*Pell-Asici*) or 'Storks' (*Pelargoi*)—significant of

wandering habits; or as being derived from the biblical *Peleg* (Gen. x. 25), from the Greek *Pelagos* (the Sea), *pelazo* (to approach), or *pelein* and *agros* (to till the field), &c.—a name, in fact, as Niebuhr says, 'odious to the historian, who hates the spurious philology out of which the pretences to knowledge on the subject of such extinct people arise'—designates a certain tribe or number of tribes who inhabited Italy, Thracia, Macedonia, a part of Asia Minor, and many other regions of Southern Europe, in prehistoric times. Ethnologically, they belong to the same race as the great stock of the earliest known settlers, that reached from the Po and the Arno to the Rhyndakus (near Kyzikus). Yet no Pelasgian town or village existing in Greece Proper after 776 B.C., speculation has, ever since the commencement of European historiography, been busy trying to supply the facts that were wanting to ascertain the exact origin and history of these predecessors of the Hellenes and Romans; and so futile have all efforts in this direction remained, that the very term Pelasgi has, from the days of Homer to our own, been used almost arbitrarily to designate either a single obscure division of a tribe like the Leleges and the Dolopes, or as equivalent for all the Greeks of a very early period.

In this latter sense, they are spoken of by Æschylus, Herodotus, Homer; while they are considered one of the branches of the race or races that peopled Greece, by Thucydides, Strabo, and most modern writers, the word thus not being a comprehensive term, like Arian, but a narrowly circumscribed one, like Hindu. Recent investigation seems, as regards their previous history, to lead to the result, that soon after the first immigration of Turanians, they, like other tribes, left their Asiatic homes, and proceeded towards Europe. They are found at a very early period settled in Asia Minor; and Homer speaks of them as allies of the Trojans. They then seem to have spread themselves, by way of the Propontis and Ægean, and again by Crete, over many of the islands between the two continents; and finally, came to occupy a great part of the Hellenic mainland—Thessaly, Epirus, the Peloponnese, Attica, Macedonia, Arcadia, provinces which, one and all, up to the latest period, bore distinct traces of the once undisputed sway of the Pelasgians. According to Herodotus, the Hellenes themselves sprang from them; and there can hardly be a doubt that they formed a most important element in the formation as well of that most gifted of nationalities, as of the Latin people. The early Etruscans (q. v.) were P. to a certain extent; and the southern tribes of the Peucetians, Enotrians, and Iapygians are distinctly declared by ancient writers to belong to their race. The step from Greece into Italy is natural enough. What caused their wanderings originally, is difficult to conjecture; but it may not unreasonably be assumed, that they were caused to a certain extent by immigrations of eastern tribes, such as the Lydians, Phrygians, Carians, who pushed them further and further west, as they took possession of their old homes.

A special stock was formed by the Tyrrhenian Pelasgi, whose gradual advance in Greece may be traced from Acarnania to Bœotia, thence to Attica, and later still, to the Hellespont, Lemnos, &c. A strong protest, however, must be recorded here on the part of some modern writers against the assumption of others, that the P. were in reality the original population of all Italy, as they were of the greatest part of Greece (Pelasgia). It is absurd, they argue, to suppose that a rich and populous nation, which had held a country like Italy for many centuries, should suddenly, just at the approach of historical times, die out without leaving even such single remnants as the Pelasgic settlements in Greece mentioned by Herodotus. These aboriginal Italian P. are, according to them, neither more nor less than a mere hypothesis of ignorant ancient writers, who wished to explain the ethnological and philological affinity between the two classical nations in an easy manner, and who, anticipating the questions about a contemporary colony, kill the whole nation off by pestilence and famine.

The Pelasgians, from what we can glean about them, would appear to have been a highly intellectual, receptive, active, and stirring people, of simple habits withal, chiefly intent upon agricultural pursuits. Several improvements in this province were distinctly traced back to them, such as the ploughing with oxen—for which purpose they had to invent the special goad; further, the art of surveying, and the like. Yet they were no less warlike when attacked and driven to self-defence; and the trumpet, which calls the widely scattered troops to the attack, was supposed to have been first used by them. That the art of navigation was well known to them, is shown sufficiently by their incessant migrations over sea and land. Of their architecture, in that style which, in default of a better name, has been called Cyclopean (q. v.), remnants are still existing.

The names Larissa, Argos, Epaphra, frequently met in ancient Greece, were bestowed by them upon their fortified cities, and are only generic names, expressive of either mountain fortresses or strongholds in plains. Wishing to remain in peace, they endeavored to keep off the invader by walls so enormously strong, that it really seems most surprising how they ever could have

been taken. Besides these, they built canals, dams, and subterranean water-works of astonishing strength and most skilful construction. The accompanying woodcut represents the tomb or

Fig. 1.—Section of Tomb of Atreus at Mycenæ.

treasury of Atreus at Mycenæ, vaulted with a fine pointed 'horizontal arch,' 48½ feet in diameter. Of their sculpture, which they no doubt likewise cultivated to a certain degree, we have but very small relics, such as a head of Medusa, and a *Xoanon* (Divine

Fig. 2.—Plan of Tomb of Atreus at Mycenæ.

Image) of Orpheus; besides these, certain traces of their special mystic worship are to be found in the archaic representations, which, though not hitherto ascribed to them, bear their direct influence upon their very face. How far they were either the inventors of the so-called Cadmean or Phœnician writing-characters, from which all European characters are derived, or merely their 'improvers,' is not to be decided by the contradictory evidence to be found on the subject; but this, at all events, is certain, that they were acquainted with the art of writing, and had thus a vast element of culture in their possession before the dawn of history.

Respecting their religion and worship, there is this only to be held with certainty, that it originally consisted in a mystic service of those natural powers, whose influence is chiefly visible in the growth of the fruits of the earth. From Egypt they obtained names for their till then nameless gods, generally called by them the Theoi; and they proceeded—by permission of the Dodonic oracle, which, together with the Pythian, they first founded—to bestow them upon them individually. Their deities were, besides the Phœnician Kabiri, Demeter, Persephone Korá, Dionysos, Hermes, Zeus of Dodona, Apollo, Hephæstus, Themis, Pan, &c. Whether those P. who inhabited Lemnos and Imbros, and who were conquered by Darius, offered up human sacrifices or not, is doubtful. An ambiguous term of Herodotus respecting the language of those small Pelasgian remnants who had survived to his day, has given rise to endless and most unsatisfactory discussions. He speaks (i. 67) of their 'barbarous language'; and the question is, whether he meant that it completely differed from Greek, or that there was only so vast a divergence of dialect, that it had become unintelligible to his contemporaries. Grote inclines to the former opinion; Niebuhr, Thirlwall, T. O. Müller, followed by G. Rawlinson and others, hold, with more apparent show of reason, that the term 'barbarous language' merely indicates a corruption or alteration of idiom, such as a long lapse of time will infallibly produce, and that it bore the same relation to the Greek of the day as the Gothic does to the German, or the Latin to any of the Romance languages, not to instance the forlorn patois of out-of-the-way places in Switzerland and elsewhere, supposed to be inhabited by unmixed descendants from Roman legions.

That other phenomenon of the vast number of roots common both to Greek and Latin—the latter, it must be remembered, having been proved to be derived, not from the former, but from the Oscean—would thus easily be explained by the assumption of a common Pelasgian linguistic (as well as ethnical) stock in both nationalities.

Their political circumstances are as unknown to us as the whole process of transition between them and the real Greek period. From a few scattered allusions, we may conclude that they were not uniformly governed; that some of their multifarious tribes

were ruled by priests, while others stood under the patriarchal rule of the head of the clan or family.

How they gradually disappeared from the rank of nations, by being either 'absorbed' by superior races (Hellenes, Italici, Carians, Lydians, Phrygians), or being reduced to nameless serf-populations, does not seem so difficult to understand as some writers would have it. Hundreds of nations have disappeared in the same manner, and we may even watch the process with our own eyes. Interesting as it might be to dwell more minutely on some of the widely divergent theories and speculations upon the P. on the part of historians, philologists, ethnologists, antiquaries, and investigators generally, to whom, at all times, this people proved exceedingly attractive, we cannot enter any further upon them here, but we shall conclude with Grote's dictum: 'If any man is inclined to call the unknown ante-Hellenic period of Greece by the name of Pelagic, it is open to him to do so. But this is a name carrying with it no assured predicates, noway enlarging our insight into real history, nor enabling us to explain what would be the real historical problem—how, or from whom, the Hellenes acquired that stock of dispositions, aptitudes, arts, &c., with which they begin their career.'

PELAYO, said by historians to have been the first Christian king in Spain, after the conquest of that country by the Arabs. Contemporary historians make no mention of him, but this may be accounted for on the ground of the insignificant size of his kingdom, which comprised only the mountainous district of Asturias. He is said to have been a scion of the royal Visigothic line, and to have retired before the conquering Arabs to the mountains of Asturias, where he maintained himself against the armies which were sent to attack him, defeating them in various pitched battles, and in numberless minor engagements. One of his most famous exploits was the destruction of a large army sent against him by Tarik, near Cangas-de-Onís. His men were posted on the heights bounding the valley through which the Arabs were to pass, and waiting till the enemy had become involved in the defile, at a given signal, overwhelmed them with enormous masses of rock. This great success caused P. to be recognized as sovereign by the surrounding districts, and the Christians flocked to him from all parts of Spain. He was much engaged in contests with the Arabs, but nevertheless found time to reanimate agriculture, superintend the reconstruction of churches, and the establishment of a civil administration. He died in 737. Such is the account given us by later historians, who trace from him the genealogy of the royal family of Spain.

PELECANIDÆ, a family of palmed birds, the *Totipalmati* of Cuvier; characterized by a long, straight, compressed bill, broad at the base, often with a pouch beneath the lower mandible; long wings, of which the first quill is the longest; short strong legs, and all the toes—including the hind toe—united by a membrane. They are generally excellent swimmers, expert divers, and birds of powerful flight. Some of them often perch on trees, which few other web-footed birds do. To this family belong pelicans, cormorants, frigate-birds, tropic-birds, and darters.

PELEW' ISLANDS, a group of islands in the North Pacific Ocean, belonging to Spain, 450 miles east of the Philippines, in lat. 7°—8° 30' N., long. 134°—136° E., at the western extremity of the Caroline Archipelago. The group includes about 20 islands, which form a chain running about 120 miles from south-south-west to north-north-east. The principal island is Babelthouap, 28 miles by 14, containing a mountain from whose summit a view of the whole group is obtained. As seen from the sea, the islands appear mountainous and rugged; but the soil is rich and fertile, and water is abundant. Bread-fruit, cocoa-nuts, bananas, sugar-cane, lemons, oranges, and other tropical trees and fruits, are grown. Cattle, fowls, and goats thrive, and fish abound on the coasts. The inhabitants, who are estimated at about 10,000 in number, are of the Malay race. They show considerable ingenuity in building their canoes, are active agriculturists, and entertain exceedingly primitive notions regarding dress, as the men go entirely naked and the women nearly so.

In 1783, the *Antelope* was wrecked upon the P. I., and the crew were treated by the natives with the greatest kindness. Further acquaintance with white men, however, seems to have altered their disposition, and several vessels, while visiting these islands, within comparatively recent years, have narrowly escaped being cut off. The islands are said to have been discovered by the Spaniards in 1545.

PELICAN (*Pelecanus*), a genus of birds of the family *Pelecanidæ* (q. v.), having a very long, large, flattened bill, the upper mandible terminated by a strong hook, which curves over the tip of the lower one; beneath the lower mandible, which is composed of two flexible bony branches meeting at the tip, a great pouch of naked skin is appended; the tongue is very short, and almost rudimentary; the face and throat are naked; the wings of moderate length, the tail rounded. The species are widely dis-

tributed, frequenting the shores of the sea, lakes, and rivers, and feeding chiefly on fish. Although birds of powerful wing, they are seldom seen at a great distance from land. All of them are birds of large size. They take their prey by hovering over the water, and plunging upon it when it appears. They often fly in large flocks, and the sudden swoop of a flock of pelicans at a shoal of fish is a striking and beautiful sight. They store up their prey in their pouch, from which they bring it out at leisure, either for their own eating, or to feed their young. The pouch is capable of being wrinkled up into small size, and of being greatly distended.

The COMMON P. (*P. onocrotalus*) is as large as a swan, white, slightly tinged with flesh color, and in old birds, the breast golden yellow. The quill-feathers are black, but are scarcely seen except when the wings are expanded. It is a native of the eastern parts of Europe, and of many parts of Asia and Africa, and frequents both the sea-coast and also rivers and lakes. It makes a nest of

Pelican (*Pelecanus onocrotalus*).

grass on the ground in some retired spot near the water, often on an island, and lays two or three white eggs. The parents are said to carry water to their young, as well as food, in their pouch. During the night, the P. sits with its bill resting on its breast. The nail or hook which terminates the bill is red, and Mr. Broderip supposes that the ancient fable of the P. feeding its young with blood from its own breast has originated from its habit of pressing the bill upon the breast, in order the more easily to empty the pouch, when the red tip might be mistaken for blood. —The RUFOUS-NECKED P. (*P. fuscus*) abounds in the West Indies and in many parts of America. Other species are found in other parts of the world, and in some places the number of pelicans is prodigious, particularly in some of the most southern parts of the world.

In Heraldry, the Pelican is drawn with her wings endorsed, and wounding her breast with her beak. When represented in her nest feeding her young with her blood, she is called a pelican *in her piety*.

PE'LION, the ancient name of a wooded mountain range in Thessaly, extending along the east coast. Its eastern side descends in steep and rugged precipices to the sea. Further to the north, near the mouth of the Peneus, is the steep conical peak of Ossa (q. v.), which, according to the classic myth, the Titans placed upon the summit of P., in order to scale Olympus, the abode of the gods. The modern name is Zagorá, and as of old, its sides and summit are clothed with venerable forests of oak, chestnut, beech, elm, and pine.

PELISSIER, AIMABLE JEAN JACQUES, Marshal of France, Duc de Malakhoft, born in 1794 at Maromme, near Rouen. His father was a small farmer, little above the degree of a peasant. P. was first sent to the Lyceum at Brussels. At twenty, he gained admission to the celebrated French Artillery college of La Flèche, and was soon transferred to the special school of St. Cyr. He entered the artillery of the Royal Guard as sub-lieutenant in 1814, and being transferred to the 57th Regiment of the line, which was not called upon to do duty after the return of Napoleon from Elba, he escaped the dilemma of declaring either for or against the Emperor. He served on the staff in Spain in 1823; made the campaign of the Morea in 1828; joined the first expedition to Algiers in 1830 as major of cavalry; and in 1839 returned to Algeria with the rank of lieutenant-colonel. He commanded the left wing of the French army at the battle of Isly. In 1845, he acquired an unenviable notoriety by suffocating more than 500 Arabs who took refuge in the caves of Oued-Riah in the Dahra. Marshal Soult, then Minister of War, did not venture to approve this atrocity, but Marshal Bugeaud, commander-in-chief in Algeria, declared that P. only carried out his positive orders. By 1850, he had attained the rank of General of Division.

When the news of the *coup d'état* reached Algiers, he espoused

Pelican, in Heraldry.

the cause of the emperor, and placed the province of Algiers under martial law until order was restored. In the war with Russia, he obtained in 1855 the command of the first corps of the Crimean army, and soon succeeded Marshal Canrobert in the chief command, when a change came over the fortunes of the campaign. The Russians were defeated on the Tchernaya, and on the 8th September the Malkhoff, the key of Sebastopol, was carried. After the fall of Sebastopol, P. received a marshal's baton, and on his return to France, was created Duc de Malakhoff and a senator, and received a dotation of 100,000 francs. He also received the order of a G.C.B. from Queen Victoria. In 1858, he came to London as the French ambassador, but resigned his post, for which he had little relish, in the following year. He was then named Governor-general of Algeria, where he died (May 1864) of congestion of the lungs.

PELLA, the ancient capital of Macedonia, and the birthplace of Alexander the Great, was situated on a hill, and surrounded by marshes. It was a wealthy and powerful city, but declined under the Romans until it became a place of no consequence, and in the middle ages there remained only a strong castle called *Bođena*. Its site has been identified with that of the village of *Neokhoris* or *Yenikioy*, near which is a spring called Pelle.

PELLLAGRA, at one time, the name of a loathsome skin-disease, supposed to be endemic to the rice-producing part of the north of Italy, is now employed to designate a group of phenomena, of which the most prominent and significant are mental. Allied affections have recently been described in various continental countries; but as presented in its most intense form in Lombardy, pellagra consists in the skin being covered with tubercles and rough scales, in debility, vertigo, inability to preserve the equilibrium, epilepsy, and great depression of spirits. The melancholia which constituted the latter stage often led to suicide, and so frequently to destruction by drowning, that it was distinguished as a special form of the tendency by the appellation of Hydromania. The extent of the ravages of this affection may be estimated from the facts, that of 500 patients in the Milan Lunatic Asylum in 1827, one third were pellagrins; that when Strambio wrote (1784), one of every twenty, and when Holland (1817), one of every five or six of the population presented symptoms of the disease. The belief, so long current, that this malady was the result of the use of rice or maize as the chief article of diet, must now be greatly modified, as it has been observed in districts and under circumstances where the food is of different description; but where poverty, insufficient nourishment, filth, toil, and the ordinary agents in human degeneration are at work.

PELLESTRINA, a town of N. Italy, in Venetia, near the center of an island of the same name, 12 miles south of Venice. Pop. 7500.

PELLET, or OGRESS, in English Heraldry, a Roundle (q. v.) sable.

PELLICO, SILVIO, an Italian poet, celebrated for his long and cruel imprisonment by the Austrians, more, perhaps, than for his verses, was born in 1798 at Saluzzo, in Piedmont, and was educated in Pignerol, where his father, Onorato Pellico, also favorably known as a lyric poet, had a silk-factory. In his 16th year, he accompanied his sister Rosina (on her marriage) to Lyon, where he remained until Foscolo's *Carme de' Sepolcri* awakened in him a strong patriotic feeling and an irresistible desire to return to Italy. Coming, about 1810, to Milan, where his family were now settled, he was warmly received by Ugo Foscolo and Vincenzo Monti, and was employed as tutor in the family of Count Porro, in whose house all the most distinguished men in Milan were accustomed to meet. His tragedies of *Laodamia* and *Francesca da Rimini* gained him an honorable name amongst Italian poets. He also translated the *Manfred* of Byron, with whom he had become acquainted. He lived in great intimacy with the most eminent patriots and authors of liberal views, and took an active part in a periodical called *Il Conciliatore*, which after a time was suppressed on account of its liberal tone. Having become connected with a secret society of the Carbonari, then the dread of the Italian government, P. was apprehended in 1820, and sent to the prison of Sta. Margherita, where his friend, the poet Maroncelli, was also confined. In the beginning of the following year, he was carried to Venice, and in January 1822, to the prison on the isle of San Michele, near Venice; and Maroncelli and he were at last condemned to death; but the emperor commuted the sentence to 20 years' imprisonment for Maroncelli, and 15 years for Pellico. In March 1822, they were both conveyed to the subterranean dungeons of the Spielberg. In August 1830, however, they were set at liberty. P. published an account of his sufferings during his ten years' imprisonment, under the title *Le mie Prigioni* (Paris, 1833), which has been translated into other languages, and has made his name familiar where it would not have been known on account of his poetry. P.'s health, never robust, was permanently injured. The Marchioness of

Barolo received him into her house at Turin as her secretary. P. subsequently published numerous tragedies and other poems, and a little catechism on the duties of man. His death took place January 31, 1854.

PELLITORY, or PELLITORY OF THE WALL (*Parietaria*), a genus of plants of the natural order *Urticæ*, having both unisexual and hermaphrodite flowers on the same plant, the perianth of both kinds 4-fid. The COMMON P. (*P. officinalis*), which grows on old walls and heaps of rubbish in Britain and many parts of Europe and Asia, is a herbaceous perennial, with prostrate branched stems, more rarely with erect stems, ovate leaves, and inconspicuous flowers. It sometimes attracts attention from the manner in which the pollen is copiously discharged in hot summer days by an elastic movement of the filaments. It was formerly much esteemed as a diuretic, refrigerant, and lithontriptic. Its properties depend on nitre, which it contains.

PELLITORY OF SPAIN (*Anacyclus pyrethrum*), a plant of the natural order *Compositæ*, of a genus nearly allied to Chamonille (q. v.), a native of the Levant and of Barbary, and cultivated to some extent in Germany and other countries. It has procumbent, branched, downy stems; each branch one-flowered; the root-leaves pinnate, with pinnatifid segments and linear-subulate lobes. The flowers (heads of flowers) have a white ray, purplish beneath, and a yellow disc. The root is spindle-shaped and fleshy, and when dried, is about the thickness of the little finger, inodorous, breaking with a resinous fracture.

It has a very peculiar taste, slight at first, but becoming acridulous, saline, and acrid, with a burning and tingling sensation in the mouth and throat, which continues for some time. It is valued in medicine, and is chewed or administered in the form of a tincture to relieve toothache, also in cases of paralysis of the tongue, as a salagogue in certain kinds of headache, and of rheumatic and neuralgic affections of the face, and is used as a gargle in relaxation of the uvula. The powder of it enters into the composition of certain cephalic snuffs, and is rubbed on the skin in certain eastern countries to promote perspiration. It is the *Radix pyrethri* of the pharmacopœias. It is a powerful local irritant. The plant cultivated in Germany has more slender roots than that of the Levant, and has sometimes been described as a distinct species (*A. officinarum*), but is probably a mere variety.

PELLS, CLERK OF THE (Lat. *pellis*, a skin), a clerk belonging to the Court of Exchequer in England and Ireland, whose office was to enter every teller's bill into a parchment or skin, called *pellis receptorum*, and also to make another roll of payments, which was called *pellis exitum*, and which showed the warrant under which the money was paid. The office was abolished in 1884 by the statute 4 and 5 Will. IV. c. 15, which transferred the duties to the comptroller-general, who thereupon assumed the custody of the records; and the Treasury thereafter established new forms of books, accounts, and warrants.

PELOPIDAS, a celebrated Theban general, of noble descent, noted among his fellow-citizens for his disinterested patriotism. The inviolable friendship between himself—one of the richest men in Thebes—and Epaminondas—one of the poorest—is among the most beautiful things recorded in Greek history. In 382 B.C. he was driven from Thebes by the oligarchic party, who were supported by the Spartans, and forced to seek refuge at Athens, whence he returned secretly with a few associates, 379 B.C., and recovered possession of the Kadmeia, or citadel, slaying the Spartan leader, Leontiades, with his own hand. Plutarch gives us a vivid picture of the adventurous exiles gliding quietly in disguise into the city on a winter afternoon, amid bitter wind and sleet. Having been elected Boeotarch, in conjunction with Melon and Charon, he set about training and disciplining his troops, so that they soon became as formidable as the Lacedæmonians, and were successful in several small encounters with the latter. His 'sacred band' of Theban youth largely contributed to the victory of Epaminondas at Leuctra (371 B.C.), but failed in a subsequent attack on Sparta itself. In the expedition of the Thebans against the cruel tyrant, Alexander of Phœnæ (368 B.C.), he was, after several important successes, treacherously taken prisoner, when in the character of an ambassador; but was rescued by Epaminondas in the expedition of the following year. He was then sent to Susa, as ambassador from Thebes, to counteract the Spartan and Athenian intrigues going on at the court of Persia, and behaved himself very nobly while there. His diplomacy was successful. In 364 B.C., a third expedition was planned against Alexander of Phœnæ, who, as usual, was threatening the Thessalian towns. The command was given to P., and in the summer he marched into Thessaly, where he won the battle of Kynoscephalæ, but was himself killed while too eagerly pursuing the foe. He was buried by the Thessalians with great pomp.

PELOPIUM was the name given, about the beginning of the present century (1802), by Rose to a new metal which he thought

he had discovered in the mineral Columbite. It was subsequently ascertained that it was identical with Niobium.

PELOPONNE'SIAN WAR. See GREECE.

PELOPONNE'SUS (i. e., the isle of Pelops), now called the Morea (q. v.), a peninsula, which formed the southern part of ancient Greece, Hellas Proper being situated to the northward of the isthmus, on which stood the city of Corinth. See GREECE. The whole area is less than 9000 square miles. In the most flourishing periods of Grecian history, the P. had a population of more than two millions, although at present it has little over half a million. Among its most important cities were Sparta in Laconia, and Argos the capital of Argolis. Sparta acquired, after the Messenian War, a decided supremacy over the other states, and disputed the supremacy with Athens in a war of almost thirty years duration (431—404 B. C.)—the famous 'Peloponnesian War,' of which the history has been written by Thucydides. After the Roman conquest, the P. formed part of the province of Achaia, and subsequently belonged to the Byzantine empire. For its later history, see MOREA.

PE'LOPS, in Greek Mythology, the grandson of Zeus, and the son of Tantalus was slain by his father, and served up at an entertainment which he gave to the gods, in order to test their omniscience. They were not deceived, and would not touch the horrible food; but Ceres, being absorbed with grief for the loss of her daughter, ate part of a shoulder without observing. The gods then commanded the members to be thrown into a cauldron, out of which Clotho brought the boy again alive, and the want of the shoulder was supplied by an ivory one. According to the legend most general in later times, P. was a Phrygian, who being driven by Ilos from Siplyos, came with great treasures to the peninsula, which derived from him the name of Peloponnesus, married Hippodamia, obtained her father's kingdom by conquering him in a chariot-race, and became the father of Atreus, Thyestes, and other sons. But in what appear to be the oldest traditions, he is represented as a Greek, and not as a foreigner. He was said to have revived the Olympic games, and was particularly honored at Olympia.

PELTRY, a general term applied to the trade in skins of wild animals, and to the skins themselves. It is understood to mean only skins undressed, except by drying, and chiefly those which, when dressed, are called furs, and it is especially applied to the produce of the North-western Territory (Hudson's Bay Territory) of British North America, although all others are included. The following table will show the kind of skins meant, and the vast destruction of animal life which is necessitated by this valuable branch of commerce.

The number and kinds of skins sold at the Hudson Bay Company's sales in 1872 were as follows:

Beaver.....	903,371
Otter.....	13,781
Sea Otter.....	59
Fur Seal.....	10,796
“ “ salted.....	1,029
Hair seal.....	8,118
Musquash.....	124,563
Fox, Silver.....	540
“ Cross.....	2,027
“ Red.....	7,699
“ White.....	2,804

Squirrel.....	643
Weenusk.....	130
Hare.....	126
Panther.....	5
Swan.....	317
Loon.....	12

Besides these there were imported in the same year the follow-

ing, chiefly for the purpose of being tanned or otherwise dressed as leather, or already prepared.

Various skins, the animals' names not given,	8,643,860
Goat and Kid, dressed and undressed.....	5,737,820
Sheep and Lamb, do.	11,043,086

The total value of these was £3,629,848. The value of skins and furs imported in 1880 was £4,359,775.

The pelts of many animals in their original state do not appear well fitted for decorative or even ordinary apparel, but the art of the furrier changes them greatly. The recent discovery, that the long hairs which project over the fine under-fur of many species, are also deeper rooted in the skin, has given rise to an easy and admirable method of removing them very completely. The pelts are stretched and passed through a paring-machine, which pares the flesh-side with such nicety that it takes off a thin layer, and cuts only through the roots of the coarse, deep-seated hairs, which are consequently easily shaken or brushed out. In this way, and by dyeing the fur, beautiful imitations of the costly seal-skins, &c., are prepared from musquash, hare, and other common pelts.

PELU'SIUM, the Greek name of an ancient Egyptian city, situated at the north-eastern angle of the Delta, and important as the key of Egypt on the Asiatic side. The eastern mouth of the Nile derived from it the epithet Pelusian (*Ostium Pelusiacum*). P. is called *Sin* in the Old Testament; and both words, as well as the native Coptic or Egyptian name *Peremoun*, or *Peromi*, signify the mud-city. The *Ostium Pelusiacum* was choked up with sand as long ago as the 1st c. B. C., and its distance from the sea has ever since been increasing. P. appears to have originally borne the name of Anaris, or Abaris. It is so called by Manetho, who attributes its foundation to the Hyksos about 2000 B. C.; but it first figures in semi-authentic history as the scene of Sennacherib's defeat, when (according to the Egyptian tradition, as reported by Herodotus), the camp of the Assyrians was invaded at night by a host of field-mice, who gnawed their bowstrings and shield-straps, so that in the morning, when the Egyptians fell upon them, they were defenceless. For the Hebrew account of Sennacherib's defeat see 2 Kings, chaps. 18 and 19. In 525 B. C., Cambyses overthrew, near P., the forces of Pharaoh-Psammethichus. The city was also taken by the Persians in 309 B. C.; and in 173 B. C., it was the scene of the defeat of Ptolemy Philometor by Antiochus Epiphanes. Mark Antony captured it, 55 B. C., and it opened its gates to Octavian after his victory at Actium, 31 B. C. Its later history is unimportant, and its ruins—at *Tineh*, near Damietta—possess little interest.

PE'LVIS, THE (from the Latin *pelvis*, a basin), is a bony ring interposed between the spinal column and the lower extremities, so as to transmit the weight of the former to the latter. Before considering the pelvis as a whole, it will be expedient to consider the individual bones of which it is composed. These, in the adult, are four in number, viz., the two ossa innominata which constitute its sides and front, and the sacrum and coccyx, which complete it behind. The *os innominatum* receives its name from its bearing no resemblance to any known body, and is a large, irregular-shaped bone. In the young subject it consists of three separate bones, which meet and form the cup-shaped cavity (the *acetabulum*), situated a little below the middle of the outside of the bone, and in which the head of the thigh-bone rests. Hence it is usual to describe this bone as consisting of the ilium, the ischium, and the pubes. The *ilium* is the superior, broad, and expanded portion which forms the prominence of the hip, and articulates with the sacrum. This bone may be described as divisible into an external and an internal surface, a crest, and an anterior and posterior border. The external surface (see fig. I.) is convex in front, and concave behind; it is bounded above by the crest, below by the upper border of the acetabulum (see fig. II.), and in front and behind by the anterior and posterior borders. It presents various curved lines and rough surfaces for the attachment of the *glutei* and other powerful muscles connecting the pelvis and the lower extremities. The internal surface, which is smooth and concave, has the same boundaries as the external, except inferiorly, where it terminates in a prominent line, termed the *linea ilio-pectinea*. The surface of the crest is convex, roughened, and sufficiently broad to admit of the attachment of three planes of muscles. The borders will be sufficiently understood by a reference to fig. I.

The *ischium* is the inferior and strongest portion of the bone. It consists of a thick and solid portion, the *body* (whose inferior border is termed the *tuberosity*), and a thin ascending portion, the *ramus*. In the ordinary sitting position, the whole weight of the body rests on the ischium; and by sitting on the hands, we can usually feel the part (the *tuberosity*, see fig. I. 15) through which the weight is transmitted. The *pubes* is that portion which runs horizontally inwards from the inner side of the acetabulum for about two inches and then descends obliquely outwards for about the same length, thus making an acute angle with its original di-

rection. The former part is called the *body*, and the latter the *ramus*, of the pubes. The ramus is continuous with the ramus of the ischium. Between the ischium and pubes is a large aperture, known as the *thyroid* or *obturator foramen*, which in the liv-

Fig. 1.
The Os Innominatum of the right side.

- 1, the ilium, its external surface; 2, the ischium; 3, the os pubis; 4, the crest of the ilium; 5, 6, upper and lower curved lines for attachment of muscles; 7, the surface for attachment of the gluteus maximus; 8, 9, the anterior superior and inferior spinous processes; 10, 11, the posterior spinous processes; 12, the spine of the ischium; 13, 14, the greater and lesser sacro-schial notches; 15, the tuberosity of the ischium; 16, its ramus; 17, the body of the os pubis; 18, its ramus; 19, the acetabulum; 20, the thyroid or obturator foramen.—(From Wilson.)

ing body is closed by a membrane termed the *obturator ligament*. The object of this large foramen is probably to give lightness to the parts, without materially diminishing their strength.

The development of the os innominatum affords an excellent example of the general principles laid down in the article *OSSIFICATION*. There are no less than *eight* centers of ossification for this bone: three primary—one for the ilium, one for the ischium, and one for the pubes—and five secondary ones for various processes, &c. The first center appears in the lower part of the ilium, at about the same period that the development of the vertebræ commences, viz., at about the close of the second month of foetal life; the second in the body of the ischium, just below the acetabulum, at about the third month; and the third in the body of the pubes, near the acetabulum, during the fourth or fifth month. At birth, the crest of the ilium, the bottom of the acetabulum, and the rami of the ischium and pubes, are still cartilaginous. At about the sixth or seventh year, these rami become completely ossified; next, the ilium is united to the ischium; and lastly, the pubes is joined to the other two in the acetabulum. The complete ossification of the bone, from the secondary centers in the crest of the ilium, the tuberosity of the ischium, &c., is not completed till about the twenty-fifth year.

Each os innominatum articulates with its fellow of the opposite side (through the intervention of the *interosseous fibro-cartilage*, which unites the two surfaces of the pubic bones, see fig. II. f),

Fig. II.

Pelvis (with Fifth Lumbar Vertebra) of European Female Adult. Transverse diameter, 5-7; antero-posterior diameter, 4-5 inches.

- 1, the last lumbar vertebra; 2, the inter-vertebral substance connecting it with the sacrum; 3, the promontory of the sacrum; 4, its anterior surface; 5, the coccyx; 6, 6, the iliac fossæ; 9, the acetabulum; a, the tuberosity, and b, the body of the ischium; c, the os pubis; f, the symphysis pubis; g, the arch; i, the spine, and k, the pectineal line of the pubis; k, l, k, l, the ileo-pectineal lines.—(From Humphry.)

with the sacrum, and with the femur (at the acetabulum). No less than thirty-five muscles are attached to this bone, some proceeding to the region of the back, others forming the walls of the abdomen, others forming the floor of the pelvis, others passing

downwards to the lower extremities, &c. As the other bones entering into the formation of the pelvis, the sacrum, and the coccyx, belong essentially to the vertebral column, and will be described in the article on that subject, it is sufficient here to remark that, collectively, they form a triangular bony mass (with the base upwards, and with a concave anterior surface), which constitutes the posterior part of the pelvic ring. See fig. II., 4, 5.

The pelvis, considered as a whole, is divisible into a false and true pelvis. The *false pelvis* is all that expanded portion which is bounded laterally by the iliac bones, and lies above the prominent line termed the *linea ileo-pectinea* (see fig. II. k, l); while the *true pelvis* is all that part of the general pelvic cavity which is situated below that line. The broad, shallow cavity of the false pelvis serves to support the weight of the intestines; while the rectum, bladder, and part of the generative organ, lie in the cavity of the true pelvis.

The upper aperture of the true pelvis is termed the *inlet*. It is somewhat heart-shaped in form, and has three principal diameters—an *antero-posterior* (or sacro-pubic), which extends from the angle formed by the sacrum with the last lumbar vertebra to the symphysis pubis, or point of union of the two pubic bones; the *transverse*, at right angles to the former, and extending across the greatest width of the pelvis; and the *oblique*, extending from the sacro-iliac symphysis (or union), on one side, to the margin of the brim corresponding with the acetabulum on the other. The diameters of the outlet are two—an *antero-posterior*, extending from the tip of the coccyx to the lower part of the symphysis pubis; and a *transverse*, from the posterior part of one ischiatic tuberosity, to the same point on the opposite side. As the precise knowledge of the diameter and depth of the pelvis is of the greatest importance in the practice of midwifery, we give the average numbers representing the dimensions of a well-formed adult female pelvis. *Diameters of inlet or brim*—antero-posterior, 4-4 inches; transverse, 5-4 inches; oblique, 4-8 inches. *Diameters of outlet*—antero-posterior, 5 inches; transverse, 4-3 inches. *Depth of the true pelvis*—posteriorly, 4-5 inches; in the middle, 3-5 inches; anteriorly, 1-5 inches.

The pelvis is placed obliquely with regard to the trunk of the body; the plane of the inlet to the true pelvis forming an angle of from 60° to 65° with the horizon. According to Naegele (*Ueber das weibliche Becken*), the extremity of the coccyx is in the female, when standing upright, about seven lines higher than the lower edge of the symphysis pubis; the upper edge of the symphysis being at the same level as the lower edge of the second segment of the coccyx. By attention to these data, a detached pelvis may readily be placed at the angle at which it normally lies in the skeleton. The shape of the human pelvis is much affected by the curving forward of the lower part of the sacrum. This bend of the sacrum forward serves to support the viscera, when the body is in an erect posture; but it is of much more importance in its relation to the act of parturition. If all the antero-posterior diameters of the true pelvis from the brim to the outlet were bisected, the points of bisection would form a curved line, similar to the curve of the sacrum, and termed the *axis* of the pelvis. As the head of the child has to follow this curve, the difficulties of parturition are much greater than if the axis of the pelvis had been straight, as in the other vertebrata. Without entering into unnecessary details, we may remark generally, that the fetal head is of oval shape, with its greatest diameter from before backwards, and that in its passage through the pelvis it is so placed that its longest diameter at each stage of labor coincides with the longest diameter of the pelvis. The head enters the pelvis with the occiput (or back of the skull) being directed towards one ilium, and the face towards the other, while, at its final emergence, the face is turned towards the sacrum and coccyx. There can be no doubt that the screw-like or rotatory motion which is thus given to the fetal head, renders its passage through the pelvis more easy than it would otherwise have been.

There are well-marked differences, chiefly having reference to the act of parturition, between the male and female pelvis. In the female, the bones are lighter and more delicate than in the male, and the muscular impressions and eminences are less distinctly marked. The iliac fossæ are large and expanded, and hence the great prominence of the hips. The several diameters (particularly the transverse diameter of the brim, which measures only 5-1 inches in the male) are somewhat greater; and the pubic arch is wider by about ten degrees; the sacrum also is wider and less curved.

It is worthy of notice that the pelvis of the negro is smaller in

Fig. III.

Pelvis, with two Lumbar Vertebrae, of a large Monkey. Transverse diameter, 2-7, and ant. ro-posterior diameter, 3 inches.—(From Humphry.)

all its dimensions than that of the European, and presents a partial approximation to that of the monkey (fig. III.), especially in the deficiency of its width. This difference is very much more obvious in the male than in the female negro; and parturition in the black races is facilitated both by the sacrum being less curved, and by the foetal head being of smaller dimensions. In the apes and monkeys, which approach most nearly to man, the pelvis is longer and narrower, and much less curved than in the human subject. In other mammals, the differences are for the most part the same in kind, but greater in degree. In many of the Cheiroptera (bats) and Insectivora (as the mole), the pubic bones are only loosely connected by a small ligament, or there is a complete opening between the bones (as occurs normally in birds), an arrangement by which the act of parturition in these animals is much facilitated.

The pelvic bones are very simple in the Cetacea, in some cases being represented by two simple elongated bones lying near the anus, and converging from opposite sides (a transverse connecting piece being sometimes but not always present); in others, by a small V-shaped bone, while sometimes (as in *Manatus*) they seem to be entirely wanting. The additional pelvic bones in the non-placental mammals have been already noticed in the articles on the *MARSUPIATA* and *MONOTREMATA*. In the echidna (belonging to the latter order), the acetabulum is perforated, as occurs normally in birds. In birds, in addition to the peculiarity just noticed, we find the pelvis open in front (or, more correctly, inferiorly), there being no union of the pubic bones in any bird except the ostrich. This normal incompleteness of the pelvic ring is obviously for the purpose of facilitating the passage of the eggs. It is unnecessary to trace the further degradation of the pelvic bones in the Reptiles and Fishes.

PE'MBA, called the Green Isle by the Arabs, an island about 20 miles off the east coast of Africa, in the dominions of the Sultan of Zanzibar, lat 5° S. Length about 38 miles. It is an irregular coraline island, cut up in every direction by creeks, which were much frequented by craft engaged in the slave-trade. The vegetation is most luxuriant, but P. is unhealthy.

PE'MBROKE, a seaport of South Wales, a market-town, and municipal and parliamentary borough, in the county of the same name, occupies a rocky ridge on a navigable creek of Milford Haven, 7 miles south-east of Milford. On the extremity of the ridge on which the town is built, are the remains of its once extensive castle, said to have been the birthplace of Henry VII. Beneath the ruins is a remarkable natural cavern, which had communications both with the castle and the harbor. In 1648, the castle was beleaguered by Cromwell, and taken after a siege of six weeks. The keep, the principal building in the inner court, is 75 feet high, and 163 feet in circumference, and is surmounted by a cone-shaped roof of masonry, still perfect. *Pater*, otherwise called Pembroke Dock, which is rather a ship-building than a commercial center, is two miles from the town, and has several building-slips and a dry-dock. The naval establishment of the government embraces an area of 80 acres, and is surrounded by a high wall, flanked by fortifications. Within P. are three ancient churches, and numerous ecclesiastical and educational institutions. Pop. (1881) of par. b., 25,309 of municipal borough 14,197. P. unites with Tenby, Milford, and Wiston in sending a member to parliament.

PEMBROKE COLLEGE, Oxford. **BROADGATES HALL**, a place of education, originally belonging in part to St. Frydeswyde's Priory, and in part to the monastery of Abingdon, was, on the dissolution of the religious houses, given to Christ Church by Henry VIII. In 1629, it was made a college by James I. and took its name from the Earl of Pembroke, the chancellor of the university. By the ordinances of the commissioners under 17 and 18 Vict. c. 81, the constitution of the college is now as follows: There are to be not less than 10 fellowships, open to all, not to exceed £200 a year in value, so long as the number of the fellowships is less than 16. There are not to be less than 12 incorporated scholarships. There are at present 24 which are tenable for 5 years—except the Townshend scholarships, tenable for 8 years—the holders, however, sharing in the emoluments during only 4 years. This college presents to 8 benefices, of which 6 have been purchased since 1812.

PEMBROKE COLLEGE, CAMBRIDGE was founded in 1347 by Mary de St. Paul, the widow of Aymer de Valence, Earl of Pembroke. She was maid, wife, and widow all in one day, her husband being slain at a tilting-match held in honor of her nuptials. On this sad event, she sequestered herself from all worldly delights, and bequeathed her estate to pious uses. Henry VI. was so liberal a benefactor to this college as to obtain the name of a second founder. There are 13 fellowships and 23 scholarships of different values.

PEMBROKESHIRE, a maritime county of South Wales, and the westernmost county of the Principality, is bounded S. by the

Bristol Channel, and W. and N. by St. George's Channel. Area, 393,682 statute acres. Pop. (1871) 91,936; (1881) 91,808. The river Teivy separates the county on the north-east from that of Cardigan. On the north are Newport and Fishguard Bays, the latter 5 miles in width, from 30 to 70 feet in depth, and with good anchoring-ground. St. Bride's Bay, the widest inlet on the western coast, is 10 miles in width, and has an inland sweep of 7 miles. Milford Haven (q. v.) is the most important estuary. The shores on the south are wild and inhospitable, and fronted by high precipitous cliffs. The surface is undulating; green hills alternate with fertile valleys. The principal elevations occur in the Precelly Hills, which traverse the north of the county from east to west, and rise in their highest summit to the height of 1754 feet. The rivers of the greatest importance are the Eastern and Western Cleddau, which unite and form a navigable portion of Milford Haven. None of the rivers, of which the Western Cleddau is the principal, are important. The climate is mild, but damp in the south of the county; while in the north, the temperature is considerably lower. There are excellent and productive soils in the south, and along the north-west coast the barley districts are famous; but the land on the Precelly Mountains and in the coal districts is inferior. Coal, slate, lead, and iron are the only minerals worked. Oats, barley, and potatoes are the principal crops. P. is chiefly remarkable from the fact that, although the most distant of Welsh counties from England, more than half its surface is inhabited by an English-speaking population. This arose from the settlement of a colony of Flemings here, and their adoption of the English tongue. The district has hence been called Little England beyond Wales. P. returns one member to parliament. The chief towns are Haverfordwest, St. Davids, Pembroke, and Tenby.

PE'MMICAN. This was originally a North American Indian preparation only, but it was introduced into the British navy victualling-yards, in order to supply the arctic expeditions with an easily-preserved food, containing the largest amount of nutriment in the smallest space. As made by the Indians, it consists of the lean portions of venison dried by the sun or wind, and then pounded into a paste, and tightly pressed into cakes; sometimes a few fruits of *Amelanchier ovata* are added, to improve the flavor. It will keep for a very long time uninjured. That made for the arctic voyagers was chiefly of beef. In making pemmican, it is necessary to remove the fat completely.

PE'MPHIGUS, or **PO'MPHOLYX**, belongs to that order of skin-diseases which is characterized by an eruption of large vesicles, filled with serous fluid, and known as *bullæ*. The disease occurs both in the acute and in the chronic form. In a mild case of acute pemphigus, bullæ, or blisters, from the size of a pea to that of a chestnut appear in succession (chiefly on the extremities), and having continued three or four days, break, form a thin scab, and soon heal, unaccompanied with febrile or inflammatory symptoms. In severe cases, there is considerable constitutional disturbance; the bullæ are larger, and the scabs heal with difficulty. The chronic form differs mainly from the acute by its prolonged continuance. The acute variety chiefly affects children, and has been ascribed to dentition, errors of diet, &c.; while the chronic form chiefly attacks aged persons, and is probably due to debility and impaired nutrition. The acute form usually requires nothing but cooling medicines and diet, and mild local dressings, such as simple cerate, to protect the raw surfaces from exposure to the air. In the chronic form, a nutritious diet, with the judicious use of tonics (iron, bark, &c.), is most commonly successful. In obstinate cases, arsenic is sometimes of use.

PEN, an instrument for writing with a fluid. In ancient times, a kind of reed (Lat. *Calamus*) was chiefly used, though sometimes the letters were painted with a fine hair-pencil, as among the Chinese at the present day. Quill-pens (see *QUILLS*) probably came into use after the introduction of modern paper. The English name pen is from Lat. *penna*, a feather; but the old form of *penna* was *pesna* or *petna* (= Gr. *peteron*), from the root *pet*, to fly; and just as Lat. *ped* is identical with Eng. *foot* (see letter F), so *petna* or *peteron* corresponds to *feather* (Ger. *feder*). During last century, many efforts were made to improve the quill-pen, the great defect of which was its speedy injury from use, and the consequent trouble of frequent mending; moreover, even the most skilful maker could not insure uniformity of quality, and any variation affected the writer's work. These efforts were chiefly directed to fitting small metal or even ruby points to the nib of the quill-pen; but the delicacy of fitting was so great, that but very little success attended the experiments. At the beginning of this century, pens began to be made wholly of metal; they consisted of a barrel of very thin steel, and were cut and slit so as to resemble the quill-pen as closely as possible. They were, however, very indifferent, and being dear (the retail price at first was half-a-crown, and subsequently sixpence), they made but little way; their chief fault was hardness, which produced a disagreeable scratching of the paper. In 1820, Mr. Joseph Gillott,

who dealt in the metal pens then made, hit upon an improvement, which, by removing this great defect, gave a stimulus to the manufacture, which has caused it to be developed to an extent truly marvelous. This consisted in making three slits instead of the single one formerly used, and by this means much greater softness and flexibility were acquired.

Mr. Gillott also introduced machinery for the purpose of carrying out his improvements, and thereby so reduced the cost of production, that he was enabled to sell his improved pens in 1821 at £7, 4s. per gross, which was then considered a remarkable success. Better pens are now sold at twopence per gross by the same manufacturer; or, in other words, 864 pens for the same price as one pen in 1821. Nor is this to be wondered at, when we are acquainted with the wonderful ingenuity of the machinery by which it is effected. The lowest-priced pens are made almost entirely by machinery, but the better ones require much hand-labor for their completion; nevertheless, in the works of Mr. Gillott alone, who is only one of several large manufacturers in Birmingham, the annual production is now nearly 150,000,000 pens, requiring a supply of five tons per week of the fine sheet-steel made for the purpose in Sheffield, a portion of which is returned as scrap or waste for re-manufacture. From Sheffield the steel is sent in sheets

Fig. 1.

about eight feet long by three feet broad; it is prepared from the best iron, generally Swedish bloom. The manufacturer then prepares it by dipping for a short time in dilute sulphuric acid, which removes the scale or black surface; the acid itself is also carefully removed by immersion in clean water; the sheets are then passed backwards and forwards through a rolling-mill with smooth rollers, which reduces the steel to the exact thickness required, and gives it greater compactness; it is next slit into strips of various widths according to the kind of pen to be made; for the ordinary kind its width is seen in fig. 1. This is then passed through a cutting-machine, which rapidly punches out pieces of the shape shown in fig. 2, and in the order shown in fig. 1, which is a portion of the strip with the pieces or blanks, as they are called, cut out; that which is represented is the waste or scrap previously referred to. The blanks are now passed through a succession of operations, each conducted by a separate person: women or girls are chiefly employed.

The first process is called *slitting*; they are passed one by one into a cutting-machine worked by a small hand-lever, which makes the two side-slits, as seen in fig. 3. The second process,

called *piercing*, is performed by a similar machine or hand-press, in which, however, only one punch acts, and that cuts out the small hole seen in fig. 4. The repeated rolling and stamping of the metal has by this time made it hard and brittle, and it is necessary to anneal it, for which purpose some thousands of the *slit* and *pierced* blanks are put into an iron box, and placed in the fire for a time, which softens them considerably; this is the third process. When cold, another operator receives them, and with another hand-press and a punch stamps or marks, as it called, the name of the maker, fig. 5, which constitutes the fourth process. The fifth is somewhat similar, and is sometimes omitted; it consists in placing it under another press, which has a punch and die for embossing any ornamental mark. The sixth process, called *raising*, consists in passing it into another press, which has a sinker and grooved die, as in fig. 6. The flat blank *a* is pushed under the sinker *c*, is pressed by the action of the lever into the groove *d*, and comes out with its edges curved up, as in *b*. The seventh process consists in *hardening*, which is done by placing the pens in an iron box or *muffle*, and when they are at a red heat, throwing them into oil;

this renders them exceedingly brittle and hard, too much so, indeed, for they have now to pass through the eighth or *tempering* process, which brings them to the required temper or hardness and elasticity. The ninth operation is *scouring*; this consists in putting a large number into a tin cylinder, which is kept revolving by machinery; sand and coarse emery-powder are mixed with them; and the friction of these materials and of the pens themselves cleanses them from all impurities, and brings out the natural color of the metal. The tenth and eleventh processes consist in grind-

Fig. 6.

Fig. 7. Fig. 8.

ing the outside of the nib, first lengthwise (fig. 7), and then crosswise (fig. 8), which are done by different persons at separate grinding-wheels.

Next follows the most important operation, constituting the twelfth process of *slitting*—that is, making the central slit, upon the nicety of which the whole value of the pen depends. This is done in a hand-press similar to the others, but the cutting part consists of two chisels, one fixed on the table, the other coming down on the depression of the lever, and so accurately adjusted as to just clear each other. The operator then skilfully holds the pen lengthwise on the fixed chisel, and brings down the movable one, so as to effect the beautifully clean cut which constitutes so important a feature in the manufacture. Two other processes, the thirteenth and fourteenth, finish the series: the first is coloring, by heating them in a revolving cylinder over a charcoal stove, which gives them a blue or yellowish color, according to the time employed; and the last is varnishing them with a varnish composed of lac and naphtha. In the works of Messrs Gillott, from inspection of which we have gathered these facts, there are 400 women and 100 men employed, and the daily produce is enormous: a clever girl will cut out 14,000 pens per day, and a good slitter will *slit* 28,000. Besides the kind specially described above, many other forms are made, especially the large and small barrel pens; but the processes are all the same, or are modifications of those described. Gold pens are extensively made in Birmingham, and as they resist the corrosive action of the ink, they are very durable; their durability is also greatly increased by the ingenious but difficult process of soldering on to the points of the nib minute particles of iridium, which, from the extreme hardness, resist wear for many years. The manufacture of iridium-pointed pens is extensively carried on in the city of New York, where the process is said to have been first brought to perfection.

PEN HOLDERS are small turned sticks, usually of cedar, and generally with a steel cylinder to fix the pen. They are used only for metal pens, and are now made by machinery, which is so ingenious, that it turns the cedar, previously cut into square sticks, round, often in a spiral or otherwise ornamental style, cuts them to the required length, and polishes and varnishes them.

PENAL SERVITUDE is a sentence for criminal offences which has been introduced in lieu of the sentence of transportation beyond the seas. See **CONVICT**; **TRANSPORTATION**.

PENALTY is a sum of money declared by some statute or contract to be payable by one who commits an offence or breach of contract. It is considered as a kind of punishment, and constituting indirectly a motive to the party to avoid the commission of the act which induces such a consequence. Many contracts executed between parties contain a clause that one or other of them who fails to perform his part of the contract, will incur a penalty, i. e., will be liable to pay a fixed sum of money to the other party. In such cases, a distinction is drawn between a liquidated and unliquidated penalty; and whether it is of the one kind or the other, depends on the language used in the contract. If it is a liquidated penalty, then, when the breach of contract is committed, the party in default must pay that precise sum, neither more nor less; but if it is unliquidated, then he is not to pay the whole sum, but merely such part of it as corresponds to the amount of injury or damage done, and of which proportion a jury is the sole judge in an action of damages. In statutes, when pen-

alties are declared to follow on certain illegal acts, the sum is sometimes fixed, but in many cases only a maximum sum is stated, it being left to the court or justices who enforce the penalty what is a sufficient punishment for the offence. Sometimes penalties can only be sued for by parties immediately injured; but, as a general rule, and unless it is otherwise restricted, anybody may sue for the penalty, for in an offence against public law, where there is no public prosecutor, any person who chooses may set the law in motion.

Accordingly, not only may anybody in general sue for the penalty, but an inducement is offered by declaring the party who does so to be entitled to the whole or a half of the penalty. Without such inducement, many offences would be unpunished. The party who so sues is generally called the informer. Thus, in offences against the game laws, anybody may sue for the penalty, and he is entitled to half of it. Sometimes the penalty can only be sued for in the superior courts of law; but in the great majority of instances, the enforcing of penalties is part of the administration of justices before justices of the peace. It is for the justices to fix the amount if they have (as they generally have) a discretion to do so. If it is not paid, the justices may issue a distress-warrant, authorizing a constable to seize and sell the goods of the party to pay the fine; and if there are no goods, then the justices may commit the party to prison as a substitutionary punishment. Sometimes justices have a discretion either to impose a penalty or commit the party to prison as an alternative punishment. All these matters depend on the construction of particular statutes.

PE'NANCE (Lat. *penitentia*), in Roman Catholic theology, means the voluntary or accepted self-inflicted punishment by which a repentant sinner manifests his sorrow for sin, and seeks to atone for the sin, and to avert the punishment which, even after the guilt has been remitted, may still remain due to the offence. Penance is believed in the Roman Catholic Church to be one of the sacraments of the New Law. It will be necessary to explain it briefly both under its relations as a sacrament, and as a private personal exercise.

Penance must be carefully distinguished from repentance, which is simply sorrow for evil-doing, accompanied with a purpose of amendment. Penance is the fruit or the manifestation of this sorrow, and it is commonly accompanied or expressed by some of those external acts which are the natural manifestations of any deep sorrow, either negative, as the neglect of ordinary attention to dress, to the care of the person, to the use of food; or positive, as the direct acts of personal mortification and self-inflicted pain, such as fasting, wearing haircloth, screwing the head with ashes, watching of nights, sleeping hard, &c. Such manifestations of sorrow, whether from motives of religion or from merely natural causes, are common among the eastern races, and are frequently alluded to in the Scripture. In the personal practice of the early Christians, penance found a prominent place, and the chief and acknowledged objects of the stated Fasts (q. v.), and other works of mortification which prevailed, was that of penitential correction, or of the manifestation of sorrow for sin.

A still more striking use of penance, however, in the early church, was the disciplinary one; and this, in the Roman Catholic view, is connected with the sacramental character of penance. Any discussion of this purely theological question would be out of place here, and it will be enough to state briefly that Roman Catholics number penance among the Seven Sacraments (q. v.), and believe it to be of direct divine institution (Matt. xvi. 19, xviii. 18; John xx. 21). The matter of this sacrament consists, in their view, of the three acts of the penitent—contrition, or heartfelt sorrow for sin, as being an offence against God; confession or detailed accusation of one's-self to a priest approved for the purpose; and satisfaction, or the acceptance and accomplishment of certain penitential works, in atonement of the sin confessed; and the form of the sacrament is the sentence of absolution from sin pronounced by the priest who has received the confession, and has been satisfied of the penitential disposition of the self-accusing sinner.

In all these points, of course, they are at issue with Protestants. Even in the apostolic times, the practice prevailed of excluding persons of scandalous life from the spiritual fellowship of the Christian community (see EXCOMMUNICATION); and without attempting to fix the date, it may be stated as certain from the authority of Tertullian and other writers, that from a very early time the persons so excluded were subjected to certain penitential regulations. The class of offenders so treated were those who had been notoriously guilty of the grievous crimes of idolatry and apostasy, murder, adultery, and other scandalous offences. The period of penitential probation differed in different times and places, but in general was graduated according to the enormity of the sin, some going so far in their rigor (see NOVATIAN) as, contrary to the clearly-expressed sense of the church, to carry it even beyond the grave. In the earlier ages, much depended upon the spirit of each particular church or country; but about the 4th c.,

the public penitential discipline assumed a settled form, which especially as established in the Greek Church, is so curious that it deserves to be briefly described. Sinners of the classes already referred to had their names enrolled, and were (in some churches, after having made a preliminary confession to a priest appointed for the purpose) admitted, with a blessing and other ceremonial, by the bishop to the rank of penitents. This enrollment appears to have commonly taken place on the first day of Lent. The penitents so enrolled were arranged in four grades, called—1. (Gr. *prosklaíontes*, Lat. *flentes*) 'Weepers;' 2. (Gr. *akroomenoi*, Lat. *audientes*) 'Hearers;' 3. (Gr. *hypopipontes*, Lat. *prosternentes*) 'Prostraters;' 4. (Gr. *syntantes*, Lat. *consistentes*) 'Standers.' Of these classes, the first were obliged to remain outside of the church at the time of public worship, and to ask the prayers of the faithful as they entered. The second were permitted to enter and to remain in the place and during the time appointed for the Catechumens (q. v.); but, like them, were required to depart before the commencement of the solemn part of the Liturgy (q. v.).

The third were permitted to pray with the rest, but kneeling or prostrate, and for them were prescribed many other acts of mortification. The fourth were permitted to pray with the rest in a standing posture, although apparently in a distinct part of the church; but they were excluded from making offerings with the rest, and still more from receiving the communion. The time to be spent in each of these grades at first differed very much according to times and circumstances, but was afterwards regulated by elaborate laws, called penitential canons. Still it was in the power of the bishop to abridge or to prolong it; a power, the exercise of which is connected with the historical origin of the practice of Indulgence (q. v.). Of these four grades, the first two hardly appear in the Western Church. It is a subject of controversy whether, and how far, this discipline was extended to other than public sinners; but it seems certain that individuals, not publicly known as sinners, voluntarily enrolled themselves among the penitents. All four grades wore a distinguishing penitential dress, in which they appeared on all occasions of public worship, and were obliged to observe certain rules of life, to renounce certain indulgencies and luxuries, and to practice certain austerities. In some churches, they were employed in the care of the sick, the burial of the dead, and other of the more laborious works of charity. The penitent, in ordinary cases, could only be restored to communion by the bishop who had excluded him, and this only at the expiration of the appointed time, unless the bishop himself had shortened it; but, in case of dangerous illness, he might be restored, with the condition, however, that, if he recovered from the illness, the whole course of penance should be completed.

The reconciliation of penitents took place commonly in Holy Week, and was publicly performed by the bishop in the church, with prayer and imposition of hands. It was followed by the administration of communion. If any of the clergy were guilty of a crime to which public penance was annexed, they were first deposed from the rank of the clergy, and then subjected to the ordeal like the laity themselves. This public discipline continued in force with greater or less exactness in the 5th, 6th, and 7th, centuries, gradually, however, being replaced by semi-public, and ultimately by private penance. In the 11th and 12th centuries, the public penance had entirely disappeared. The nature and origin of private penance is a subject of controversy between Catholics and Protestants; the former contending that it had existed from the first, and that it held the same place even in the ages of public penance for secret sins which the public penance did for public offences. At all events, from the date of the cessation of the public discipline, it has existed universally in the Roman Church. The priest, in absolving the penitent, imposes upon him the obligation of reciting certain prayers, undergoing certain works of mortification, or performing certain devotional exercises. These acts of the penitent are held to form an integral part of the sacrament of penance.

According to Protestants, penance has no countenance whatever from Scripture, and is contrary to some of the most essential principles of the Christian religion; particularly to the doctrine of justification by faith in Jesus Christ alone, on the ground of his complete or 'finished' work; penance being, in fact, founded on a doctrine of—at least—supplementary atonement by the works or sufferings of man—the sinner—himself. The outward expressions of humiliation, sorrow, and repentance common under the Jewish dispensation, are regarded as very consistent with the character of that dispensation, in which so many symbols were employed.

It is also held, that the self-inflicted austerities, as fasting, sackcloth and ashes, &c., of Jewish and earliest Christian times, had for their sole purpose the mortification of unholy lusts and sinful passions in the people of God; or the expression of sorrow for sin, so that others beholding might be warned of its evil and restrained from it; all which is perfectly consistent with the principles of Christianity, if kept within the bounds of moderation and discretion. But penance in any other view, as a personal exercise,

is utterly rejected. Arguments founded on the meaning of the two Greek words *metanceo* and *metameleomai*, both translated in our English version, *repent*, are much urged by many Roman Catholic controversialists—the former being represented as equivalent to the English *Do Penance*; but this is condemned by Protestants as inconsistent with the very use of the words in the New Testament itself. That penance began, as a practice, very early in the Christian church, is not only admitted by Protestants, but alleged in proof of the very early growth of those corruptions which finally developed themselves in the doctrines and practices of the Roman Catholic Church, and of which Protestants also hold that there are plain intimations in the New Testament, not only prophetic, but showing the development of their germs to have already begun during the age of the apostles.

In the discipline of the Protestant churches, penance is now unknown. The nearest approach to the Roman Catholic polity on the subject was that in use among the English Puritans of the 17th c., and more particularly in the Church of Scotland during that and the succeeding century, when it was common 'to make satisfaction publicly on the Stool of Repentance' (q. v.). It does not seem to have occurred to the Reformers or their more immediate successors in the Protestant churches, that their system of discipline, with its public rebukes and enforced humiliations of various kinds—as the wearing of a sackcloth robe, and sitting on a particular seat in church—was liable to be interpreted in a sense very different from that of a mere expression of sorrow for sin; but the belief is now very general among the most zealous adherents of their doctrinal opinions, that in all this they adopted practices incongruous with their creed, and in harmony rather with that of the Church of Rome. Nor do they seem to have perceived that Church-Discipline (q. v.), in its proper sense, as relating to ecclesiastical rights and privileges, is wholly distinct from the imposition of penalties by churches or church courts. Penitential humiliations, imposed by ecclesiastical authority, are now no more in favor where church discipline is most strict, than where the utmost laxity prevails. The commutation of penalties deemed shameful, for a fine to the poor of the parish, was an abuse once prevalent in Scotland, but never sanctioned by the higher ecclesiastical authorities.

PENANG. See **PRINCE OF WALES ISLAND.**

PENANG LAWYERS, the commercial name for the stems of a species of palm imported from Penang for walking-sticks. They are small and hard, and have a portion of the root-stock attached, which is left to form the handle.

PENATES. See **LARES, MANES, and PENATES.**

PENCILS are instruments for writing, drawing, and painting, and they differ as much in their construction as in the uses to which they are applied. Probably the pencil was the first instrument used by artists, and consisted then of lumps of colored earth or chalk simply cut into a form convenient for holding in the hand. With such pencils were executed the line-drawings of Aricides the Corinthian, and Telephanes the Sicynian, and also the early one-colored pictures, or *monochromata*, of the Greeks and Egyptians; but as wet colors began to be used, small fine-pointed brushes would be required, and we find it recorded that as early as the 4th c. B.C., several Greek artists had rendered the art of painting with hair-pencils so famous, that some of their pictures sold for vast sums of money. There are now in use the following kinds of pencils: hair-pencils, black-lead pencils, chalk-pencils, and slate-pencils. The first are used for painting or writing with fluid colors, either oil or water, and in China and Japan are employed almost entirely instead of pens for writing; the color used being the black or brown pigment obtained from various species of sepia or cuttle-fish. The manufacture of hair-pencils is of great importance, and requires much care and skill. The hairs employed are chiefly those of the camel, badger, sable, mink, kolinski, fitch, goat, and the bristles of hogs; and the art of pencil-making requires that these hairs shall be tied up in cylindrical bundles, so nicely arranged that all their naturally fine points shall be in one direction, and that the central one shall project the furthest, and the others in succession shall recede, so that, collectively, the whole shall form a beautifully smooth cone, the apex of which is a sharp point. Black-lead pencils are made of graphite or plumbago, which contains no lead whatever in its composition, but is in reality almost pure carbon. See **BLACK-LEAD.** The misnomer is probably owing to the fact, that, previous to the employment of graphite for making pencils, common lead was used, and this was the case even within the present century. Consequently, as the plumbago, with its black streak, offered a contrast to the pale one of the lead, it was called in contradistinction *black-lead*.

The best graphite for drawing-pencils is found in the Cumberland mines, which have long been celebrated. Within the last twenty years, however, vast deposits of this mineral, of a very fine quality, have been discovered in Siberia and other parts of the Russian empire. Inferior qualities are found in Austria and

Prussia, in Ceylon, and various parts of North America; but they are rarely used in pencil-making, except for very inferior kinds. Black-lead is rarely sufficiently free from sand and other foreign ingredients to be used without preparation; it is therefore generally ground fine, and levigated or washed until it is pure, and again formed into solid blocks by means of enormous pressure, generally in hydraulic presses; these blocks are then sawn into thin plates about the sixteenth of an inch in thickness, which are again cut across, so as to form them into small square sticks.

It may appear a very simple process to press the powdered graphite into blocks, but it was found so difficult in practice as almost to prevent the employment of this method, which has led to immense improvement in pencil-making. It was found at first that the difficulty of pressing out the contained air was so great that the presses were broken under the weight required; pressure in a vacuum was then tried, but the difficulty of applying it was found almost insurmountable, and it was certainly unprofitable. Mr. Brokendon of London, who has long been famous for his pencils, at last surmounted the difficulty by an ingenious and very simple process. This consists in compressing this black-lead into blocks two or three inches square, with only moderate pressure; these are then coated over with paper, well glued, so that, when dry, the covering is air-tight. A small hole is now made through this coating on one side, and several of these cubes of black-lead are put under the receiver of an air-pump, and the air being exhausted completely from them, the orifice in each is closed by an adhesive wafer, which prevents the return of the air when they are taken out of the receiver. They are next placed under the hydraulic press, and a well-sustained and regular pressure is brought to bear upon them for twenty-four hours, after which they are found to be so completely consolidated, that in cutting them the substance is equal in density to the best specimens of unprepared graphite.

There is so large a variation in the color of various qualities of blacklead, that, by a judicious mixture of them, when in the powdered state, almost any shade of darkness can be procured; but instead of thus carefully combining different qualities of graphite, it is a common practice to add sulphur or sulphuret of antimony, and by heating to procure the desired degree of blackness. For very inferior pencils, the worst quality of black-lead is mixed with black chalk and size, or gum-water, and formed into a paste, of which the pencil is made.

It is usual to enclose the material constituting the essential part of the pencil in a case of wood, for its protection from breakage, and to prevent its soiling the hands. The wood (generally cedar) is first sawn into thin boards, about half the thickness of the intended pencils; these are then cut into small pieces about ten inches long, by six in width, which are placed in the cutting and grooving machine. This machine consists principally of two circular saws—one very thin, and so set that it will cut through the board; the other revolving within the eighth of an inch of it, so set as only to cut a fine square groove in the wood. By means of this machine, the little boards are cut into straight square sticks, each having a groove on one surface. Into these grooves, the little prepared sticks of black-lead are laid and covered with a similar piece of wood, but not grooved. A workman, who is called the 'fastener-up,' having glued the inner faces of the two pieces of wood, presses them together, and sets them to dry; after which they are passed through the rounding-machine, dressed with a semi-circular smoothing-plane, cut at the ends, and then polished by rubbing them with a piece of shark-skin. The last process is stamping them with the maker's name and the letter which designates their peculiar quality. These letters are H, HH, HHH, B, BB, BBB, HB, FS. H signifies *hard*; repeated twice and thrice, it means *harder* and *very hard*. B means *black*, HB hard and black, and so on. FS signifies *fine stroke*.

Chalk-pencils are made in a similar manner, only that finely-powdered colored chalks, such as are used for crayons, are substituted for the black-lead. Previous to pressing and cutting the chalk, it is mixed with a little hot melted wax, which gives it softness and adhesiveness.

Slate-pencils for writing on slate are made either by cutting slate into sticks, and rounding them, or by cutting it into fine square slips, and encasing them in wood, as in the case of black-lead, &c.

PENDANT, or **PENNANT**, is a narrow flag of great length, tapering to a point, and carried at the head of the principal mast in a royal ship, to show that she is in commission. In the British navy, the pendants are borne of three colors—red, white, or blue—according to the color to which the admiral commanding the fleet pertains. See **FLAG-OFFICER.** A *broad-pennant* is a blue pennant, shorter and broader than the above, carried at the mast-head of a commodore's ship, to denote that her captain is the commodore on the station. A first-class commodore hoists his broad-pennant at the fore; if of the second-class, his flag flies at the mizzen.

The *rudder-pendants* are strong ropes spliced in the rings of the rudder-chain, to prevent the loss of the rudder, should it by any accident become unshipped.

PENDANT, a hanging ornament, used in ceilings, vaults, stair-cases, timber-roofs, &c. It is sometimes a simple ball, and sometimes elaborately ornamented, and is chiefly used in the later Gothic and Elizabethan styles.

PENDENTIVE, the portion of a vault resting on one pier, and extending from the springing to the apex.—The word pendentive is also applied to the portions of vaults introduced in the angles of rectangular compartments, in order to reduce them to a circular or other suitable form to receive a dome.

PEN'DLETON, a township of Lancashire, with a station on the Lancashire and Yorkshire Railway, is a suburb of Manchester, and is $2\frac{1}{4}$ miles west-north-west of the town of that name. In 1871, it contained 30,652 inhabitants; and in 1881, the population had increased to 48,409. P. is part of the parliamentary borough of Salford, and since 1852 it has been incorporated with the municipality of the same borough. The rapid increase of its population is due to the immense industry of the locality. The inhabitants are employed in the numerous cotton and flax mills, print and dye-works, iron foundries, soap, and chemical works, in operation here. Hundreds of the population are also employed in the well-known P. collieries, which are conducted with much enterprise by the lessees. P. is also the residence of a portion of the mercantile community from Manchester, whose large mansions, with their parks and gardens, are dotted at intervals along the two roads leading from the township westward to Eccles.

PENE'DO, a flourishing town of Brazil, in the province of Alagoas, near the mouth of the San Francisco. Pop. 9000.

PEN'DULUM, in its widest scientific sense, denotes a body of any form or material which, under the action of some force, vibrates about a position of stable equilibrium. In its more usual application, however, this term is restricted, in conformity with its etymology (Lat. *pendeo*, to hang), to bodies suspended from a point, or oscillating about an axis, under the action of gravity, so that, although the laws of their motion are the same, *Rocking Stones* (q. v.), *Magnetic Needles*, *Tuning-forks*, *Balance wheel of a watch*, &c., are not included in the definition.

The *simple pendulum* consists (in theory) of a heavy point or particle, suspended by a flexible string without weight, and therefore constrained to move as if it were always on the inner surface of a smooth spherical bowl. If such a pendulum be drawn aside into a slightly inclined position, and allowed to fall back, it evidently will oscillate from side to side of its position of equilibrium, the motion being confined to a vertical plane. If, instead of being allowed to fall back, it be projected horizontally in a direction perpendicular to that in which gravity tends to move it, the bob will revolve about its lowest position; and there is a particular velocity with which, if it be projected, it describes a circle about that point, and is then called a *conical pendulum*. As the theory of the simple pendulum can be very easily explained, by reference to that of the conical pendulum, we commence with the latter, which is extremely simple. To find the requisite velocity, we have only to notice that the (so-called) *Centrifugal Force* (q. v.) must balance the tendency towards the vertical. This tendency is not directly due to gravity, but to the tension of the suspending cord. In the fig. let O be the point of suspension, OA the pendulum in its lowest position, P the bob in any position in the (dotted) circle which it describes when revolving as a conical pendulum; PB, a radius of the dotted circle, is evidently perpendicular to OA. Now, the centrifugal force is directly as the radius PB of the circle, and inversely as the square of the time of revolution.

Also the radius PB is $PO \sin$. BOP, the length of the string multiplied by the sine of the angle it makes with the vertical; and the force towards the vertical is proportional to the earth's attraction, and to the tangent of the above angle—as may be at once seen from the consideration that the three forces acting on the bob at P are parallel, and therefore proportional, to the sides of the triangle OBP. Hence the square of the time of revolution is directly as the length of the string and the sine of the angle BOP, and inversely as the earth's attraction and the tangent of the same angle; or (what is easily seen to be equivalent) to the length of the string and the cosine of its inclination to the vertical directly, and to the earth's attraction inversely. Hence, in any given locality, all conical pendulums revolve in equal times, whatever be the lengths of their strings, so long as their heights are equal; the height being the product of the length of the string by the cosine of its inclination to the vertical. Also the squares of the times of revolution of conical pendulums are as their heights directly, and as the earth's attraction inversely.

Now, so long as a conical pendulum is deflected only through a very small angle from the vertical, the motion of its bob may be considered as compounded of two equal simple pendulum oscillations

in directions perpendicular to each other, such as it appears to make to an eye on a level with it and viewing it at some distance, first from one point, say on the north, and then from another 90° round, say on the east. And these motions take place, by Newton's second law (see *MOTION, LAWS OF*), independently. Also the time of a (double) oscillation in either of these directions is evidently the same as that of the rotation of the conical pendulum. Hence, for *small arcs of vibration*, the square of the time of oscillation of a simple pendulum is directly as its length, and inversely as the earth's attraction. Thus, the length of the second's pendulum at London being 39.1393 inches, that of the half-second's pendulum is 9.7848 inches, or one fourth; that of the two seconds' pendulum 156.5572 inches, or four times that length.

Fig. 1.

Fig. 2.

It follows from the principle now demonstrated, that so long as the arcs of vibration of a pendulum are all small relatively to the length of the string, they may differ considerably in length among themselves without differing appreciably in time. It is to this property of pendulum oscillations, known as *Isochronism* (q. v.), that they owe their value in measuring time. See *HOROLOGY*.

That the times of vibration of different pendulums are as the square roots of their lengths, may be demonstrated to the eye by a very simple experiment. Suspend three musket balls on double threads as in the figure, so that the heights in the dotted line may be as 1, 4, and 9. When they are made to vibrate simultaneously, while the lowest ball makes one oscillation the highest will be found to make three, and the middle ball one and a half.

A pendulum of *given length* is a most delicate instrument for the measurement of the relative amounts of the earth's attraction at different places. Practically, it gives the kinetic measurement of gravity, which is not only by far the most convenient, but also the true measure. By this application of the pendulum, the oblateness of the earth has been determined, in terms of the law of decrease of gravity from the poles to the equator. The instrument has also been employed to determine the mean density of the earth (from which its mass is directly derivable), by the observation of its times of vibration at the mouth and at the bottom of a coal-pit. It was shown by Newton, that the force of attraction at the bottom of a pit depends only upon the internal nucleus which remains when a shell, everywhere of thickness equal to the depth of the pit, has been supposed to be removed from the whole surface of the earth. The latest observations by this method were made by Airy, the present astronomer-royal, in the Harton coal-pit, and gave for the mean density of the earth a result nearly equivalent to that deduced by Cavendish and Maskelyne from experiments of a totally different nature. See *EARTH*.

If the bob of the simple pendulum be slightly displaced in any manner, it describes an ellipse about its lowest position as center. This ellipse may, of course, become a straight line or a circle, as in the cases already considered. The bob does not accurately describe the same curve in successive revolutions; in fact, the elliptic orbit just mentioned rotates in its own plane about its center, in the same direction as the bob moves, with an angular velocity nearly proportional to the area of the ellipse. This is an interesting case of *progression of the apse* (Apsides, q. v.), which can be watched by any one who will attach a small bullet to a fine thread; or, still better, attach to the lower end of a long string fixed to the ceiling a funnel full of fine sand or ink which is allowed to escape from a small orifice. By this process, a more or less permanent trace of the motion of the pendulum is recorded, by which the elliptic form of the path and the phenomena of progression are well shown.

According to what is stated above, there ought to be no progression if the pendulum could be made to vibrate simply in a straight line, as then the area of its elliptic orbit vanishes. It is, however, found to be almost impossible in practice to render the path absolutely straight; so that there always is from this cause

a slight rate of change in the position of the line of oscillation. But as the direction of this change depends on the direction of rotation in the ellipse, it is as likely to affect the motion in one way as in the opposite, and is thus easily separable from the very curious result obtained by Foucault, that on account of the earth's rotation, the plane of vibration of the pendulum *appears to turn* in the same direction as the sun, that is, in the opposite direction to the earth's rotation about its axis.

To illustrate this now well-known case, consider for a moment a simple pendulum vibrating at the *pole* of the earth. Here, if the pendulum vibrates in a straight line, the direction of that line remains absolutely fixed in space, while the earth turns round below it once in 24 hours. To a spectator on the earth, it appears, of course, as if the plane of motion of the pendulum were turning once round in 24 hours, but in the opposite direction. To find the amount of the corresponding phenomenon in any other latitude, all that is required is to know the rate of the earth's rotation about the vertical in that latitude. This is easy, for velocities of rotation are resolved and compounded by the same process as forces, hence the rate at which the earth rotates about the vertical in latitude λ is less than that of rotation about the polar axis in the ratio of $\sin. \lambda$ to 1. Hence the time of the apparent rotation of the plane of the pendulum's motion is— $\frac{24 \text{ hours}}{\sin. \lambda}$. At the pole,

this is simply 24 hours; at the equator, it is infinitely great, or there is no effect of this kind; in the latitude of Edinburgh ($56^\circ 57' 28.2''$) it is 28.63 h., or 28 h. 37 m. 48 s.

We have not yet alluded to the obvious fact, that a *simple* pendulum, such as we have described above, exists in theory only, since we cannot procure either a single heavy particle, or a perfectly light and flexible string. But it is easily shown, although the process cannot be given here, that a rigid body of any form whatever vibrates about an axis under the action of gravity, according to the same law as the hypothetical simple pendulum. The length of the equivalent simple pendulum depends upon what is called the Radius of Gyration (q. v.) of the pendulous body. Its property is simply this, that if the whole mass of the body were collected at a point whose distance from the axis is the radius of gyration, the moment (q. v.) of inertia of this heavy point (about the axis) would be the same as that of the complex body. The square of the radius of gyration of a body about any axis, is greater than the square of the radius of gyration about a parallel axis through the center of gravity, by the square of the distance between those lines. Now, the length of the simple pendulum equivalent to a body oscillating about any axis is directly as the square of the radius of gyration, and inversely as the distance of the center of gravity from the axis. Hence, if k be the radius of gyration of a body about an axis through the centre of gravity, $\sqrt{k^2 + h^2}$ is that about a parallel axis whose distance from the first is h ; and the length, l , of the equivalent simple pendulum is $l = \frac{k^2 + h^2}{h}$.

This expression becomes infinitely great if h be very large, and also if h be very small (that is, a body vibrates very slowly about an axis either far from, or near to, its center of gravity). It must therefore have a minimum value. By solving the equation above as a quadratic in h , we find that l cannot be less than $2k$, which is, therefore, the length of the simple pendulum corresponding to the quickest vibrations which the body can execute about any axis parallel to the given one. In this case, the value of h is equal to k . Hence, if a circular cylinder be described in a body, its axis passing through the center of gravity, and its radius being the radius of gyration about the axis, the times of oscillation about all generating lines of this cylinder are equal, and less than the times of oscillation about any other axes parallel to the given one. Also, since the formula for l , above given, may be thus written, $h(l - h) = k^2$, it is obvious that it is satisfied if $l - h$ be put for h . Hence, if any value l (of course not less than $2k$) be assigned as the length of the equivalent simple pendulum, there are *two* values of h which will satisfy the conditions; that is, there are two concentric cylinders, about a generating line of either of which the time of oscillation is that of the assigned simple pendulum. When $l = 2k$, these cylinders coincide, and form that above described. And since the sum of the radii of these cylinders is l , it is obvious that if we can find experimentally two parallel axes, about which a body oscillates in equal times, and if the center of gravity of the body lie *between* these axes, and in their plane, the *distance between these axes is the length of the equivalent simple pendulum*. This result is of very great importance, because it enabled Kater (who was the first to employ it) to use the complex pendulum for the determination of the length of the simple second's pendulum in any locality. The simple pendulum is perfect in theory, but cannot be constructed; and thus the method which enables us to obtain its results by the help of such a pendulum as we can construct, is especially valuable.

Compensation Pendulum.—As the length of a rod or bar of any

material depends on its temperature (see *HEAT*), a clock with an ordinary pendulum goes faster in cold, and slower in hot, weather. Various contrivances have been devised for the purposes of diminishing, if not destroying, these effects. The most perfect in theory, though perhaps not the most available in practice, is that of Sir D. Brewster (q. v.), founded upon the experimental discovery of Mitscherlich, that some crystals *expand* by heat in one direction, while *contracting* in the perpendicular one; and therefore that a rod may be cut out of the crystal in such a direction as not to alter in length by any change of temperature. In the method of correction usually employed, and called *compensation*, advantage is taken of the fact that different substances have different coefficients of linear dilatation; so that if the bob of the pendulum be so suspended as to be raised by the expansion of one substance, and depressed by the expansion of another, the lengths of the effective portions of these substances may be so adjusted that the raising and depression, taking place simultaneously, may leave the position of the bob unaffected. There are two common methods of effecting this, differing a little in construction, but ultimately depending on the same principle. Of these, the *mercurial* pendulum is the more easily described. The rod AC, and the framework CB, are of steel. Inside the framework is placed a cylindrical glass jar, nearly full of mercury, which can be raised or depressed by turning a nut at B. By increase of temperature, the steel portion AB is lengthened by an amount proportional to its length, its coefficient of linear dilatation, and the change of temperature, conjointly—and thus the jar of mercury is removed from the axis of suspension. But neglecting the expansion of the glass, which is very small, the mercury rises in the jar by an amount proportional to its bulk, its coefficient of cubical dilatation, and the change of temperature conjointly. Now, by increasing or diminishing the quantity of mercury, it is obvious that we may so adjust the

Fig. 3.

instrument that the length $\left(\frac{k^2}{h}\right)$ of the equivalent simple pendulum shall be unaltered by the change of temperature, whatever be its amount, so long as it is not great enough to sensibly change the coefficients of dilatation of the two metals. The screw at B has nothing to do with the *compensation*, its use is to adjust the length of the pendulum so that it shall vibrate in one second.

The construction of the *gridiron* pendulum will be easily understood from the cut. The black bars are steel, the shaded ones are brass, copper, or some substance whose coefficient of linear dilatation is more than double that of steel. It is obvious from the figure that the horizontal bars are merely connectors, and that their expansion has nothing to do with the vibration of the pendulum, so they may be made of any substance. It is easily seen that an increase of temperature lowers the bob by expanding the steel rods, whose effective length consists of the sum of the lengths of Aa, BC, and the steel bar to which the bob is attached; while it raises the bob by expanding the brass bars, whose effective length is that of one of them only; the other, as well as the steel rod bc, being added to the instrument for the sake of symmetry, strength, and stiffness only. If the effective lengths of steel and brass be inversely as their respective dilatation coefficients, the position of the bob is unaltered by temperature; and therefore the pendulum will vibrate in the same period as before heating. This is on the supposition that the weight of the framework may be neglected in comparison with that of the bob; if this weight must be taken into account, the requisite adjustments, though possible, are greatly more complex, and can only be alluded to here. Practically, it is found that a strip of dry fir-wood, carefully varnished, to prevent the absorption of moisture, and consequent hygrometric alterations of its length, is very little affected by change of temperature; and in many excellent clocks, this is used as a very effective substitute for the more elaborate forms just described. To give an idea of the nicety which modern astronomy requires in the construction of an observing clock, we may mention that the Russian astronomers find the gridiron superior to the mercurial pendulum; because differences of temperature at different parts of the clock case (though almost imperceptible in a properly protected instrument), may heat the steel or the mercury unduly in the latter; while, in the former, the steel and brass bars run side by side through the greater part of the length of the pendulum, and are thus simultaneously affected by any such alterations of temperature.

Fig. 4.

It would lead us into details of a character far too abstruse for the present work to treat of the effects of the hydrostatic pressure and viscosity of the air upon the motion of a pendulum.

PENELOPE, in Homeric legend, the wife of Ulysses (Odysseus), and mother of Telemachus, who was still an infant when

Ulysses went to the Trojan war. During his long wanderings after the fall of Troy, he was generally regarded as dead, and P. was vexed by the urgent suits of many lovers, whom she put off on the pretext that she must first weave a shroud for Laertes, her aged father-in-law. To protract the time, she undid by night the portion of the web which she had woven by day. When the suitors had discovered this device, her position became more difficult than before; but fortunately Ulysses returned in time to rescue his chaste spouse from their distasteful importunities. Later tradition represents P. in a very different light, asserting that by Hermes (Mercury), or by all her suitors together, she became the mother of Pan (q. v.), and that Ulysses, on his return, divorced her in consequence. But the older Homeric legend is the simpler and more genuine version of the story.

PENGUIN (*Aptenodytes*), a genus of birds of the family *Alcidae* (see **AUK**), or constituting the family *Aptenodidae*, regarded by many as a sub-family of *Alcidae*, and divided into several genera or sub-genera. They have short wings, quite unfit for flight, but covered with short rigid scale-like feathers, admirably adapted for swimming, and much like the flippers of turtles. The legs are very short, and are placed very far back, so that on land penguins rest on the tarsus, which is widened like the sole of the foot of a quadruped, and maintain a perfectly erect posture. Their bones, unlike those of birds in general, are hard, compact, and heavy, and have no air-cavities; those of the extremities contain an oily marrow.

The body is of an elliptical form; the neck of moderate length; the head small; the bill moderately long, straight, more or less compressed; the tail very short. Some of them have a long, slender, and pointed bill, the upper mandible a little curved at

Penguin (*Aptenodytes pennatis*).

the tip, and feathered for about a third of its length; some, sometimes called Gorfews or Gorfous (*Chrysocoma*) have a stout and pointed bill, a little curved at the tip; some, *Sphenisques* or *Spheniscans* (*Spheniscu*), have a straight and compressed bill, irregularly furrowed at the base. The Penguins are all among the most aquatic birds, although they are seldom seen very far out at sea; but it is only in the breeding season that they spend much time on shore. They are found only in the southern hemisphere, and chiefly in high southern latitudes, although some of the species extend into warm regions, as *Spheniscus Humboldtii* to the coast of Peru. Of this species, which is called *Pazaro nino*, or Child Bird, by the Peruvians, Tschudi states that it is easily tamed, becomes very sociable, and follows its master like a dog, waddling along in a very amusing manner with its plump body and short legs, keeping its balance by motions of its little wings. It displays considerable intelligence, and learns to answer to its name. In some of the furthest antarctic regions, penguins are prodigiously numerous, appearing on the shore like regiments of soldiers, or, according to another simile, which has been used by a voyager, like bands of little children in white aprons.

They often occupy for their breeding ground a space of several acres, which is laid out and levelled and divided into squares, as nicely as if it had been done by a surveyor; whilst between the compartments they march as accurately as soldiers on parade. The **KING P.** (*A. Patagonica*), a large species, of the size of the great auk, dark grayish-blue above, white beneath, with a black head and a yellow curved band on the throat, is found in such numbers on some of the sandy antarctic coasts, that Mr. Bennett describes one breeding ground on Macquarie Island as covering thirty or forty acres, and to give some notion of the multitudes, speaks of 30,000 or 40,000 birds as continually landing and as many putting to sea. On many of the antarctic shores, the pen-

guins do not flee from nor seem to dread the presence of man, remaining as if stupidly indifferent, even when their companions are knocked on the head; their very indifference, it is said, suggesting the idea of loneliness and desolation more powerfully than if there were a total absence of life. When attacked, however, they often show courage in self-defence, and are ready to run with open bill at an invader. The young are reckoned good eating; the old are said to be black and tough. The name P. is said to be derived from the Latin *pinguis*, fat.—Penguins make no nest, but lay a single egg in a chosen place on the shore; and the egg is carefully tended both by male and female. The female P. keeps charge of her young for nearly twelve months.—Many of the penguins are birds of bright plumage.—Cuttlefish, and other *Cephalopoda*, form a great part of their food. Their voice is loud and harsh, between a quack and a bray, but there are many diversities in the different species.

PENICILLA'RIA. See **GUINEA CORN** and **MILLET**.

PENITENTIAL PSALMS, seven of the Psalms, of David, so called as being specially expressive of sorrow for sin, and accepted by Christian devotion as forms of prayer suitable for the repentant sinner. They are Psalms vi., xxxii., xxxviii., li., ciii., cxxx., and cxlii., according to the Authorized Version, which correspond with vi., xxxi., xxxvii., l., ci., cxix., and cxlii. of the Vulgate. These Psalms have been set apart from a very early period, and are referred to as such by Origen (Hom. ii. in Leviticum). Pope Innocent III. ordered that they should be recited in Lent. They have a special place in the Roman Breviary, and more than one of the popes attached an indulgence to the recital of them. The most deeply penitential, and the most frequent in use, both public and private, is the 51st Psalm, or the *Miserere* (50th in the Vulgate).

PENITENTIARIES, strictly so called, are institutions for the reception of penitent women, in which confinement is purely voluntary. The name has also been applied to prisons under the separate system, having been adopted by the Quakers of Pennsylvania in 1786, when they caused the legislature of that state to abolish the punishments of death, mutilation, and the whip, and to substitute solitary confinement as a reformatory process. (See **CONVICT**, **PRISON DISCIPLINE**.) The P. of the first mentioned kind are often known as Magdalen Asylums or Female Refuges. Most of the institutions of this kind in the United Kingdom are associated under the auspices of the Reformatory and Refuge Union, an association which embraces also reformatories, industrial schools, and other like institutes. In 1877 the union had on its list 65 P. or homes for fallen women in England (15 in London), and 12 in Ireland and Scotland. In the Magdalen asylums, the inmates remain in the strictest seclusion for periods varying from a few months to two years, the average time being about a year; they then return to their friends, or to situations provided for them. It is an invariable rule not to dismiss any save the entirely incorrigible, without seeing that they are provided with the means of honest subsistence. During their seclusion, they are employed in needlework, washing, and housework. Most of the provincial and metropolitan establishments have been created in the last twenty years.

The oldest institution is the London Magdalen Hospital (with room for 140 penitents), opened in 1758; the next that of Dublin (for 20 persons), in 1766; the Edinburgh Magdalen Asylum (with room for 70 persons), in 1797. All the rest (including a large one at Glasgow, with accommodation for 146 penitents) have been founded in the present century. The results of these P., as far as they can be ascertained, are excellent. During the last hundred years, the London Magdalen committee state that they have found from their extensive experience that 70 per cent. are permanently reformed. All the institutions can show a very large percentage restored to their friends and to society.

PENITENTIARY (Lat. and Ital. *penitentiaria*), the name given to one of the offices of the Roman court, and also to the dignitary (a cardinal, called *Penitentiarius*) who presides over it. The cardinal penitentiary must be a priest and a doctor of theology or canon law. He is named by the pope himself, and should the penitentiary die while the Roman see is vacant, the cardinals must be specially assembled to elect by secret scrutiny a pro-penitentiary to act for the time. The officials of the penitentiary under the cardinal penitentiary, are a regent, three secretaries, three clerks, a corrector, a consultant in theology, and another in canon law, and one or two minor officers. The subjects which come under the notice of the penitentiary are all matters relating to the confessional, especially the absolution from sins and from canonical censures, reserved to the pope, and in certain cases dispensations from the impediments of marriage.

PENN, WILLIAM, a celebrated English Quaker and philanthropist, the founder of the colony of Pennsylvania, was the son of Sir William Penn, an eminent English admiral, and was born at London, 14th October 1644. His early years were spent

partly in Essex and partly in Ireland, where his father had several estates. P. studied at Christ Church, Oxford, and while here was converted to Quakerism by the preaching of a disciple of George Fox, named Thomas Loe. His enthusiasm for his new faith assumed a pugnacious form. Not only did he object personally to attend the services of the Church of England, and to wear the surplice of a student—both of which he considered eminently papistical—but, along with some companions who had also become Quakers, he attacked several of his fellow-students, and tore the obnoxious robes from their backs. For this unseemly proceeding P. was expelled from the university. His father was so excessively annoyed at his conduct, that he gave P. a beating, and turned him out of doors; but he soon afterwards mollified, and sent his son to travel on the continent, in the hope that change of scene and the gaiety of French life would change the bent of his mind. They failed, however, to effect this, but the youth certainly acquired a grace and suavity of address that he did not before possess. In 1666 the admiral sent him to Ireland to look after his estates in the county of Cork, which P. did to his father's complete satisfaction; for in matters of business he was as practical an Englishman as in religion he was an out-and-out mystic. In the city of Cork, however, he again fell in with Thomas Loe, and for attending a Quaker meeting was, along with some others, imprisoned by the mayor, but was immediately afterwards released on appealing to the lord president of the Council of Munster, who was personally acquainted with him.

On his return to England, P. and his father again quarrelled, because the 'conscience' of the former would not allow him to take off his hat to anybody—not even to the king, the Duke of York, or the admiral himself. P. was again turned out of doors by his perhaps testy, but assuredly provoked parent. The mother, however, stepped in, and smoothed matters so far that P. was allowed to return home, and the admiral even exerted his influence with the government to wink at his son's attendance at the illegal conventicles of the Quakers, which nothing would induce him to give up. In 1668, however, he was thrown into the Tower, on account of a publication entitled *The Sandy Foundation Shaken*, in which he attacked the ordinary doctrines of the Trinity, God's 'satisfaction' in the death of Christ, and justification by the imputation of Christ's righteousness. While in prison he wrote the most famous and popular of his books, *No Cross, no Crown*, and *Innocency with her Open Face*, a vindication of himself, which contributed to his liberation, which was obtained through the interference of the Duke of York. In September 1670, Admiral Penn died, leaving his son an estate of £1500 a year, together with claims upon government for £16,000. In 1671, the upright but incorrigible secretary was again committed to the Tower for preaching, and as he would not take an oath at his trial, he was sent to Newgate for six months. Here he wrote four treatises; one of them, entitled *The Great Cause of Liberty of Conscience*, is an admirable defence of the doctrine of toleration. After regaining his liberty he visited Holland and Germany, along with Fox and Barclay, for the advancement of Quakerism. The Countess Palatine Elizabeth, the granddaughter of James I., showed him particular favor. On his return, he married, in the beginning of 1672, Guilelma Maria Springett, daughter of Sir William Springett, and for some years thereafter continued to propagate, by preaching and writing, the doctrines of his sect.

Circumstances having turned his attention to the New World, he, in 1681, obtained from the crown, in lieu of his monetary claim upon it, a grant of the territory now forming the state of Pennsylvania. P. wanted to call it Sylvania, on account of its forests; but the king (Charles II.) good-humoredly insisted on the prefix Penn. His great desire was to establish a home for his co-religionists in the distant West, where they might preach and practise their convictions in unmolested peace. P., with several friends sailed for the Delaware in August 1682, was well received by the settlers, and on the 30th November held his famous interview with the Indian tribes, under a large elm-tree at Shackamaxon, now Kensington. He next planned and named the city of Philadelphia, and for two years governed the colony in the wisest, most benevolent, and liberal manner. Not only Quakers, but persecuted members of other religious sects, sought refuge in his new colony, where, from the first, the principle of toleration was established by law. Having called the colonists together, he gave the infant state a constitution in twenty-four articles. Towards the end of the reign of Charles II., Penn returned to England to exert himself in favor of his persecuted brethren at home. His influence with James II.—an old friend of his father's—was so great that many people then, and some even yet, do not feel quite satisfied about the nature of their relations; but the suspicion that he allowed himself to be used as a tool by the court is really not justified by any known facts. It is possible, for his position was equivocal, but it is not proven, and Lord Macaulay—who has urged the view of his complicity in some of the disgraceful incidents that followed Monmouth's rebellion with an ungracious animosity—has been convicted of haste and inaccuracy

in several important particulars. At any rate, his exertions in favor of the Quakers were so far successful, that in 1686 a proclamation was issued to release all persons imprisoned on account of their religious opinions, and more than 1200 Quakers were set free. In the April following, James issued an edict for the repeal of all religious tests and penalties, but the mass of Nonconformists mistrusted his sincerity, and refused to avail themselves of it.

After the accession of the Prince of Orange as William III., P. was twice accused of treason, and of corresponding with the exiled monarch, but was acquitted. In 1690 he was arrested on a charge of conspiracy, but was again acquitted. Nevertheless, in the following year, the charge was renewed. Nothing appears to have been done for some time, but P. at last, through the kindly offices of his friends, Locke, Tillotson, and others, had the matter thoroughly investigated, and he was finally and honorably acquitted, November 1693. Shortly after, his wife died, but in less than two years he married again. His second wife, Hannah Calowhill, was a Bristol lady. In 1699 he paid a second visit to the New World, and found Pennsylvania in a prosperous condition. His stay, which lasted two years, was marked by many useful measures, and by efforts to ameliorate the condition both of the Indians and Negroes. P. departed for England towards the end of 1701, leaving the management of his affairs to a Quaker agent named Ford, whose villany virtually ruined Penn. When the rogue died, he left to his widow and son false claims against his master, and these were so ruthlessly pressed, that P. allowed himself to be thrown into the Fleet in 1708, to avoid extortion. His friends afterwards procured his release, but not till his constitution was fatally impaired. P. died at Buscombe, in Berkshire, July 30, 1718. He left issue by both marriages. Upon the P. controversy it is unnecessary further to enter. We refer our readers to Macaulay's *History of England* (1849—1855); Hepworth Dixon's *Life of Penn* (new edit. 1856); J. Paget's *Inquiry Into the Evidence of the Charges brought by Lord Macaulay against William Penn* (1858); and Stoughton's *William Penn* (new ed. 1838).

PE'NNALISM, the name given to a practice once prevalent in the Protestant universities of Germany, which seems to have been essentially the same as the Fagging (q. v.) of the English public schools. The freshmen or students of the first year (called *pennals*—i. e., *pen-cases*; fags) were considered by the elder students ('schorists') as virtually their servants. Whatever property the pennals had they must give up to the schorists, who now employed them in the meanest offices, made laughing-stocks of them, and beat and ill-used them—all which had to be endured without complaint. After a year of this discipline followed the ceremony of 'deposition'—a practice older than pennalism itself, and borrowed probably from knightly consecration—in which the pennal underwent a number of symbolical trials, indicative generally of purgation from impurity and consecration to an intellectual life. Pennalism is said to have been introduced in the beginning of the 17th c., and to have been mostly confined to the Protestant universities of Germany. But although the full development of the system may have been thus restricted, germs and modifications of it were much earlier and more general, as is manifest from the prevalence of names of contempt for first year's students (see *BE-JAN*), and from statutes passed by French universities as early as the middle of the 14th c., against levying payments for first footing from them. See also *FAGGING*. The servitude imposed on the pennals was probably an aping of the usage of chivalry, by which a candidate for knighthood had to serve for a time as a page to one already a knight. All attempts to check the evils of pennalism were long unavailing, as the pennals took part with the schorists in resisting all regulations of the authorities, which would have deprived them of the hope of exercising in their turn a like tyranny upon others. Edicts against the practice were issued in Jena and other universities about the beginning of the 17th c., but it was not till the last half of the century that the universities, by uniting in severe measures, were able to check the evil; and traces of it survived for a long time afterwards. In imitation of the students, a kind of pennalism was adopted by other bodies, more particularly by the printers, who retained the ceremony of 'deposition' after it had disappeared from the universities—Schöttgen, *Historie des Pennalwesens* (Dresd. 1747).

PENNANT, THOMAS, LL.D., tourist, naturalist, and antiquary, was born June 14, 1726, at Downing, in Flintshire, and educated at Queen's and Oriel Colleges, Oxford. His first important publication was the *British Zoology* (1761—1769), which contained in all 132 plates on imperial paper, engraved by Mazel, and established his reputation. While the work was in course of publication, P. made a trip to the continent, and saw some of the scientific and literary celebrities of the time, as Buffon, who has favorably mentioned him in his great work on *Natural History*, Voltaire, Haller, the two Gesners, and Pallas. In 1769, he made the first of his famous tours in Scotland, penetrating to the remotest part of the country, which, he says, was then 'almost as

little known as Kamtschatka.' He returned with a very good opinion of it, and published his report in 1771, in consequence of which (according to him) Scotland has 'ever since been *inondée* with Southern visitants.' The year before, he added 103 plates to his *British Zoology*, with descriptive notices; and in 1771, printed at Chester his *Synopsis of Quadrupeds*, subsequently enlarged and improved under the title of *History of Quadrupeds*. Of this work Cuvier says: 'It is still indispensable to those who wish to study the history of quadrupeds.' In the same year the university of Oxford conferred on him the degree of LL.D. Next year he undertook his second and most important tour in Scotland, which included a voyage to the Hebrides (an account of which appeared in 3 vols. 1775). P. was warmly welcomed by the inhabitants. Almost every corporated town paid him some formal compliment, and he returned 'rich in civic honor.' In 1778, he published his *Genera of Birds*, and made an antiquarian tour through the north of England. His subsequent tours through Wales do not require special notice. In 1777 appeared a fourth volume of his *British Zoology*, containing the Vermes, the Crustaceans and the Testaceous Animals of the Country. Among a great variety of later miscellaneous publications, we may mention in particular an amusing life of himself (*The Literary Life of the late Thomas Pennant, Esq., by himself*, 1793). He died December 16, 1798.

PENNA'TULA, a genus of zoophytes (*Anthozoa*), allied to *Gorgonia* (q. v.) and *Alegonium* (q. v.), and having very similar polypes; but the polype mass is not fixed by its base, has a fleshy stem strengthened by a bone, and a skin containing calcareous spiculae the upper part of the stem winged on two sides with numerous pinnae, along the upper margins of which the polype-cells are ranged. The whole form somewhat resembles a quill, so that the popular name SEA PEN is very often given to these zoophytes. One species, *P. phosphorea*, is common on the northern parts of the British coast. It is from two to four inches in

Pennatula (*Virgularia mirabilis*).

length, of a purplish-red color, and like many—perhaps all—of the other species, is sometimes brilliantly phosphorescent, emitting flashes of light when disturbed, but ceasing to be luminous on relapsing into quiescence. The stalk is hollow in the center, and the bone which it contains—and which is composed of phosphate and carbonate of lime, like the bones of the vertebrate animals—is a very remarkable part of its structure, not extending the whole length of the stalk, slender, straight, and perfectly simple, but bent backwards at each end into a hook. Other species are found in the Mediterranean and other seas, some of them more pen-like than even the British one. It has been alleged that they swim by contractions and dilatations of their common fleshy substance, or by movements of the pinnae; but there is no good evidence of their possessing any such power of locomotion, which is very contrary to the analogy of all similar zoophytes, and more probably the opinion prevalent among the fishermen of the Scottish coasts is the correct one, that their natural place is at the bottom of the sea, with the somewhat flexible lower end of the stalk immersed in mud.

Nearly allied to the pennatulæ is another genus of extremely beautiful zoophytes, *Virgularia*, ranked with them in the family *Pennatulidæ*, and sometimes receiving the popular name SEA RUSH. One species, *V. mirabilis*, is found on the British coasts. It resembles a slender rod, bearing throughout the greater part of its length two rows of lobes, along the margin of which the polypes are arranged. The whole length is from six to ten inches.

PE'NNON, a small, pointed, or swallow-tailed flag, carried by the medieval knight on his lance, bearing his personal device or badge, and sometimes richly fringed with gold. The device was so placed as to appear in its proper position when the weapon was laid for the charge.

PE'NNONCELLE, a long streamer-like flag, the diminutive of the Pennon (q. v.).

PENNSYLVANIA, one of the thirteen original United States of America, now the second in population, and called from its position and importance 'the Keystone State,' is in lat. 39° 43'—42° 15' N., long. 74° 75'—80° 37' W. It is bounded N. by Lake Erie and New York; E. by New York and New Jersey, from which it is separated by the Delaware River; S. by Maryland and

Virginia; and W. by Virginia and Ohio. The small state of Delaware borders for a few miles on its south-eastern angle. The form is very regular, the boundaries of three sides being lines of latitude and longitude. It is 310 miles long, 160 wide, containing an area of 42,215 square miles, or 28,937,600 acres, divided into 66 counties. The state is divided near the middle by the Alleghenies into an eastern region, whose waters fall into the Delaware and Chesapeake Bays, and a western, in which the principal rivers are the Alleghany, the Monongahela, and other important affluents of the Ohio.

These, with the Delaware and Susquehanna, Lehigh, Schuylkill, and Juniata, are the principal rivers. The chief towns are Philadelphia, on its south-eastern border; Pittsburgh, at the head of the Ohio; and Harrisburgh, the capital, on the Susquehanna. The Blue Ridge, which enters the south-eastern portion of the state, rises to the height of 1500 feet; the passes of the Alleghenies are 2000 feet high, and single peaks 3000 feet. Lake Erie is 565 feet above the ocean. The geological formations range from the Potsdam sandstones to the coal-measures. There is middle secondary red sandstone and drift in the north-east; gneiss and red sandstone in the south-east; the center of the state is a rich and fertile limestone valley. Near Philadelphia are fine quarries of white marble. The great anthracite and semi-anthracite deposits of coal are east of the Alleghenies; west are the great beds of bituminous coal; three counties of P. in 1880 produced about 25 per cent. of the whole coal product of the States. Salt is found beneath the coal, and in the bituminous districts great deposits of petroleum. Adjacent to the coal-measures are rich beds of iron ore, also lead, copper, nickel, and zinc ores. The climate is mild, and the soil fertile, producing abundance of wheat, Indian corn, oats, rye, buckwheat, potatoes, flax, hemp, tobacco, hay and pasture, apples, pears, peaches, grapes, &c. P. has also a large industry engaged in mines and manufactures, coal, iron, woollen, and cotton. At Pittsburgh, about 57,000 hands are employed in the coal and iron industries. In 1880, the state possessed near 7000 miles of railway; above 30 colleges; several theological, medical, and normal schools, and above 17,000 public schools; nearly 6000 churches, and 1400 public libraries. There are two state penitentiaries (one on the solitary system), 6 asylums for the insane, 2 institutions for deaf-mutes, 2 for the blind orphans' schools, &c. In 1627 a colony of Swedes and Finns settled on the river Delaware. In 1681 the territory was granted by Charles II. to William Penn, who, by the industry of his co-religionists, the Society of Friends, by cultivating peace with the Indians and encouraging emigration, founded a rich and flourishing state. It was the scene of Braddock's defeat in the French war; and in the revolution of 1776, Philadelphia was the chief city and capital of the Federation, near which were the actions of Germantown, Brandywine, &c. The population, largely Scottish and German in its origin, was in 1800, 602,361; in 1820, it was 1,049,468; in 1870; 3,521,951; and in 1880, 4,282,891.

PENNY, a British coin and money of account. After the Scættæ (q. v.) it is the most ancient of the English coins, and was the only one generally current among the Anglo-Saxons. The name is evidently the same as the German *pfennig*, and both words seem to be intimately connected with the old German *pfant*, a pledge, and the Latin *pendo*, to weigh or to pay. Both in Britain and on the continent the word was anciently used for money in general, hence we have such phrases as, 'he has got his penny-worth,' i.e., he has got value for his money, &c. The penny is first mentioned in the laws of Ina, king of the West Saxons, about the close of the 7th century. It was at this time a silver coin, and weighed about $2\frac{1}{4}$ troy grains, being thus about $\frac{1}{144}$ th of the Saxon pound-weight. This relation to the pound-weight is evidently derived from the usage of the early Franks, who retained the Roman division of the *libra* into 20 *solidi*, and the *solidus* into 12 *denarii* (the denarius being thus the 240th part of the *libra* or pound. See MARK. Halfpence and farthings were not coined in England till the time of Edward I., but the practice previously prevailed of so deeply indenting the penny with a cross mark, that the coin could be easily broken into two or four parts as required. Silver farthings ceased to be coined under Edward VI., and silver halfpennies under the Commonwealth. By this time the penny had steadily decreased in weight; it was 18 grains under Edward III., 15 and 12 under Edward IV., 8 under Edward VI., and under Elizabeth it was finally fixed at $7\frac{1}{4}$ grains, or $\frac{1}{16}$ of an ounce of silver, a value to which the subsequent copper pennies, which till 1860 were the circulating medium, closely approximated. In 1672 an authorized copper coinage was established, and halfpence and farthings were struck in copper. The penny was not introduced till 1797, and at the same period the coinage of twopenny pieces was begun; but these latter, being found unsuitable, were withdrawn. The penny of the present bronze coinage is of only about half the value of the old copper penny. The German *pfennig* was also originally a silver coin, bearing the same relation to the German pound of silver as the English penny to its pound.

The old Scottish penny was only $\frac{1}{4}$ th of the English one, as the pound Scots and the Scots shilling were also $\frac{1}{4}$ th of the English coins of the same name. In the 12th c. it was made very broad and thin.

In the beginning of the 14th c. the mark of silver was anew divided into 60 parts or coins, which, to distinguish them from the old coins, were called *grossi denarii*, whence the term *groschen*. In the currency of the German Empire, the pfennig is a nickel coin, the hundredth of the mark, the latter being equal to a shilling.

PENNYROYAL, a species of Mint (q. v.). The name P. is given in North America to a small plant, *Hedeoma pulegioides*, allied to the mints, and having, like them, a pleasant aromatic

Pennyroyal.

smell, and a warm pungent taste; which is much in use in domestic medicine, in the form of a warm infusion, to promote perspiration and as an emmenagogue.

PENNY WEDDINGS, or **PENNY BRIDALS**, was the name given to festive marriage ceremonials in Scotland, at which the invited guests made contributions in money (seldom more than 1s. each), to pay the general expenses, and leave over a small sum, which would assist the newly-married pair in furnishing their dwelling. This practice, now disused, was prevalent in the 17th c.; and, as leading to 'profane minstrelsy and promiscuous dancing,' was denounced by an Act of the General Assembly of the Kirk, 1645, as well as by numerous acts of presbyteries and kirk-sessions about the same period.

PENOBSCOT, a river of Maine, U. S., rises near the center of the state by two branches, from a chain of lakes extending north-westerly; and after a south by west course of 135 miles from the junction, or 275 in all, empties into Penobscot Bay, a broad and sheltered opening into the Atlantic Ocean, 20 miles wide, with several large islands. Its chief towns are Belfast, at its mouth; Bangor, 50 miles above, where falls supply power to saw-mills and factories; Castine, and Bucksport. It is navigable to Bangor, where there is a tide of 20 feet. The chief trade is pine-timber.

PENRITH, a market town of Cumberland, in a picturesque and fertile valley, with rich and striking scenery in the vicinity, stands on the Carlisle and Lancaster Railway, 17 miles south-south-east of Carlisle. In the parish churchyard is a monument of great antiquity, formed of two pyramidal stones about 12 feet high, and known as the 'Giant's Grave.' The town contains an ancient free grammar-school, and other educational institutions. A new and beautiful church, built in the style of the 13th c., was consecrated here in 1850. There are iron-foundries, saw-mills, and breweries. Pop. (1871) 8317; (1881) 9263.

PENRYN, a municipal and parliamentary borough and market town of England, in the county or Cornwall, in a warm, sheltered, and richly productive valley, on the Plymouth and Falmouth Railway, two miles west-north-west of Falmouth. It stands on a low hill projecting eastward into Falmouth Harbor. Trade is carried on to some extent with the mining district of Redruth, and there are several quarries in the vicinity, from which the famous P. granite—the material of which Waterloo Bridge, the Chatham Docks, and a great number of other important public works are constructed—is obtained; 20,000 tons of granite have been exported in the year, but the quantity varies much. Pop. (1881) of municipal borough, 3463. Together with Falmouth, it forms a parliamentary borough, which returns two members to parliament.

PENSACOLA, a city and port of entry, on a deep bay opening into the Gulf of Mexico, at the south-western extremity of West Florida, U. S. The town is on the north shore of the bay, and is connected by railway with Montgomery, Alabama. Population (1880) 6846. Nine-tenths of the business part of P. were burned down in a great fire, November 1880. Near the entrance are the navy yard, hospital, and Fort Barrancas. The entrance is further defended by Fort Pickens, at the west end of Santa Rosa Island, and Fort M'Rae on the opposite point. The bay branches into two divisions, receiving the Escambia and Yellow Rivers. As one of the best harbors on the gulf, P. was settled by the Spaniards, occupied by the British in 1814, and acquired by the United States in 1821.

PENSION (Lat. *pensio*, from *pendo*, to weigh out, to pay), an allowance paid annually by government to an individual in consideration of past services, civil or military. See **CIVIL LIST**.

PENSIONS AND PENSIONERS, MILITARY AND NAVAL. There are pensions for good service, for mere faithful ordinary service, for wounds, and to representatives of deceased officers.

Good-Service Pensions are rewards to selected officers in the British navy for distinguished service. In 1873 they were as follows: 12 admirals had £300 each, 25 captains £150, 1 general of marines £300, 5 do. £200, 2 colonels £150, and 5 medical officers £100; total, £9150. In 1875–1876, the total was £7500. The corresponding pension in the army is called a **REWARD FOR DISTINGUISHED SERVICE** (q. v.).

The *Pensions for Long Service* are awarded in the army to non-commissioned officers and soldiers who have served 21 years in the infantry, or 24 years in the cavalry, or earlier if disabled from further service, according to the wounds, loss of health, and conduct of the pensioner. The amount is fixed by the commissioners of Chelsea Hospital, and varies from 1½ d. to 3s. 6d. a day, the lower rates being mainly confined to negro pensioners from the West India regiments. Pensioners are either *in-pensioners* of Chelsea (q. v.) or Kilmainham Hospitals, in which case they forego their proper pension, and receive board, lodging, and a small sum for tobacco-money, or out-pensioners residing where they please, and drawing their pensions from the staff officers of pensioners, of whom there is one in every considerable town. These men can follow other pursuits, often do so with great success, as their military habits of regularity stand them in good stead in civil life. In particular, railways give employment to great numbers of pensioners, as signalmen, guards, &c. Pensioners who are in good health, and are willing for such service, are enrolled in a force called the 'Enrolled Pensioners,' which forms a defensive corps of veterans, and belongs to the Army of Reserve. This gives the men, as an adjunct to the pension, an annual retaining fee of £1 each, besides pay during the yearly training of 8 days, at the rate of 2s. a day for privates, 2s. 6d. for corporals, and 3s. for sergeants. The veterans are officered by their respective staff officers, and in case of emergency, would be embodied for service. As garrison troops, these old soldiers would doubtless prove most valuable. A pension is forfeited if the holder be convicted of felony. The number of pensioners for 1875–1876 was 63,234, and their pensions amounted to £1,193,600, besides £7500 to Malta Fencible Artillery, &c. These were exclusive of 538 in-pensioners of Chelsea, and about 180 of Kilmainham; the cost of those establishments together being £34,334.

The *Naval Pensions for Long Service* are given to petty officers, seamen, and marines under principles essentially similar to those for the army, except that there are now no in-pensioners. The commissioners of the Admiralty award the allowances, and the pensioners draw their pensions through the staff officers of military pensioners. Under the old arrangement there were in-pensioners, whose home was Greenwich Hospital. In 1875–1876, 20,234 engineers, warrant-officers, seamen, marines, &c., received pensions, producing a total of £471,758.

Under this section should be mentioned pensions for especial bravery in action, granted with the Victoria Cross (q. v.).

Pensions for *wounds* are common to both services, and are limited to officers. They are awarded respectively by the Secretary for War and Lords of the Admiralty, for serious bodily injury, as the loss of a limb or eye, and vary according to the rank of the recipient and other circumstances. In cases of less serious injury, temporary pensions are sometimes granted, or gratuitous. The charge for pensions for wounds for 1875–1876 was—army, 172 recipients, £16,443; navy, 85 recipients, £9086; total, £25,479. In the case of common soldiers and sailors, wounds may serve to hasten or augment the pension for service (see above); but they have no distinctive pension for wounds.

Widows of commissioned and warrant officers in the army and navy receive pensions so long as they remain unmarried, provided they have been married severally twelve months when their husbands die, and that the latter were under 60 years of age (50 for warrant officers) when they married the claimants. Such pension

is not granted if the widow be left in wealthy circumstances, and lies dormant during a second marriage, though it may be revived should she again become a widow. The amount of pension varies according to rank, and there are three distinct classes for each rank: 1st, When the husband was killed in battle, or died within six months of wounds received therein; 2d, When he died from some cause distinctly falling within the sphere of his duty, but not from wounds in action; 3d, When he died in the course of nature. The following table shows the amount of pension to widows of combatant ranks, civil ranks receiving similar rates according to relative standing. See **RELATIVE RANK**.

Widow of	PER ANNUM.		
	1st Class.	2d Class.	3d Class.
Flag Officer, or General } Officer.....	According to circumstances.		£120
Captains in Navy; } Colonels in Army; }.....	£200	{ 105 Cpts. 150 Cols. }	80 & 90
Lieutenant-Colonels in } Army.....	200	140	80
Commanders in Navy; } Majors in Army; }.....	120	100	70
Lieutenants, Navy } Captains, Army }.....	80	65	50
Sub-Lieutenants, Navy....	60	50	40
Lieutenants, Army.....	60	50	40
Sub-Lieutenants, Army....	50	40	36
Gunners, Boatswains, } Carpenters, Navy, }.....	35	30	25

Compassionate allowances are small additional pensions granted to the children of deceased officers, left in indifferent or bad circumstances. They vary from £5 to £40 each, and can be held by boys till 18 (unless earlier provided for), and by girls until 21, or an earlier marriage. If an officer fall in action, without leaving a widow or orphans, but leaving a parent who had been more or less dependent on him, such parent may be granted the pension or a portion of it, and is sometimes allowed to commute the pension into a single payment. In very special cases, the sisters of an officer, who had been more or less dependent on him, are granted compassionate allowances. The pensions to soldiers' wives and allowances to their orphans, &c., amounted in 1875-1876 to a total of £146,938. The corresponding figure for widows and orphans of sailors was £173,086.

The following are the principal relevant items from the estimates for 1881-82: *Army*.—For distinguished services, £33,960; to widows and orphans, £124,250; for wounds, £16,990; hospital, £33,887; out-pensions, £1,386,500. *Navy*.—For meritorious services, £6500; for wounds, £7724; pensions to engineers, warrant officers, &c., £77,192; to widows and relatives of officers, £136,742; to seamen and marines for wounds, &c., £565,247.

PENSIONARY, GRAND, OF HOLLAND. See **GRAND PENSIONARY**.

PENTA'CRINUS, a genus of *Echinodermata* of the order or family *Crinoidea* (q. v.), remarkable as containing the only permanently stalked *Crinoidea*, or *Crinoidea* believed to be permanently stalked, known now to exist, and thus the only true living representative of the fossil *Encrinites* (q. v.). The genus *P.* has a long pentagonal column of numerous joints, from which there arise at intervals many whorls of unbranched arms, and which bears at its summit a disc at first divided into five radiating members, and afterwards branching into ten arms, each further subdivided. The whole of this skeleton is calcareous, but it is united by cartilages, and covered with a fleshy integument. *P. Caput Medusæ*, the *MEDUSA'S HEAD*, is found in the West Indian seas, and is very rare in collections, being only dredged up from waters of considerable depth; from which cause also the nature of the base of the column is not certainly known. The stem is more than a foot long.—The fossil species of *P.* are numerous in the Lias and Oolite formations. They gradually become fewer in the newer rocks.—The stalked young of *Comatula rosacea* was at one time regarded as a *P.*, and described under the name of *P. Europæus*. See **CRINOIDEÆ**.

PENTADE'SMA, a genus of trees of the natural order *Guttifera*, to which belong the **BUTTER-AND-TALLOW TREE** of Sierra Leone, *P. butyracea*. It is a tree sixty feet high, and produces a conical fruit of the size of a very large pear, the pulp of which abounds in a yellow oily substance, with a strong flavor, somewhat resembling that of turpentine, yet much used by the natives as an article of food.

PENTAGON is a plane geometrical figure of five sides. When the sides are equal, the figure is called a regular pentagon.

PENTASTYLE, a building with a portico of five columns.

PE'NTATEUCH (Gr. fivefold book), a name given by Greek translators to the five books ascribed to Moses, which are in Hebrew called collectively *Torah* (Law), by way of eminence, or *Chamisha Chumshe Torah* (five-fifths of the Torah). *Law* is also the general name by which the work or portions of it are referred to and quoted (the words 'of Moses' or 'of the Lord' being added occasionally) both in the Old and New Testament.

The division into five portions (further divided into 50, 40, 27, 36, 34 chapters, or 12, 11, 10, 10, 11 Parshioth or Sidras respectively, by the Masoretes) is, if not original, at all events of a very remote date, and certainly anterior to the Septuagint. Genesis, Leviticus, and Deuteronomy, the first, third, and fifth books, form clearly defined and internally complete parts of the work as a whole, and thus, also, fix the limits of the intermediate second (Exodus) and the commencement of the concluding fifth (Deuteronomy). The chief aim of the Pentateuch being to give a description of the origin and history of the Hebrew people up to the conquest of Canaan, together with the theocracy founded among them, the center is formed by the person of Moses himself, the regenerator and lawgiver of the nation. Genesis, beginning with the history of the creation and antediluvian genealogy from Adam to Noah, in rapid outlines sketches the propagation of the various tribes that descended from the one man who was saved in the Deluge, but dwells with special emphasis upon Shem, from whom sprang, in the tenth generation, Abraham, the progenitor of the 'people of the covenant.'

The salient events in the lives of his descendants, the Patriarchs, are minutely described; and a fitting close is found in the benediction of Jacob, who, as it were, reinaugurates and confirms all his twelve sons in the covenant made between Abraham and God. Exodus, treating of the liberation of the people from Egypt; their wanderings in the desert; the promulgation of the Law, by which they became emphatically the 'holy nation' and the 'people of the Lord;' and the erection of a visible sanctuary; may be regarded as the nucleus of the work; while Leviticus, the following book, fittingly enters into the details of the legislation and the mode of worship; especially the prescriptions concerning sacrifices, festivals, ceremonial purity, and the duties of the priests, with but little of history. The historical thread is taken up again in Numbers, the fourth book, which, also, side by side with the relation of the events between the Sinaitic period and the beginning of the fortieth year after the Exodus, contains many laws explanatory of, or complementary to, those of the former books, together with such as new circumstances had called into existence. A brief recapitulation of the preceding portions; Moses's most impressive and reiterated exhortations to keep that Law, which was now completed, and solemnly transmitted to the Levites; and the death of the legislator himself; form the chief contents of the fifth book, or Deuteronomy. Thus, the theocratic plan of the work is carried through from beginning to end, coming out more prominently in the three intermediate books, but never lost sight of entirely. Nothing is dwelt or even touched upon save that which in some way illustrates either the relation of God to the people, or of the people to God; the political, civil, and domestic laws themselves, being enumerated only as bearing upon the main aim and object of the work.

The special books being treated separately under their respective heads, we have here only to consider some questions relating to the work as a whole, and principally that of its authorship and history, as far as these points have not been touched upon already under **GENESIS**. Tradition, as embodied in the earliest historical records, mentions Moses as the writer of the complete Pentateuch, such as it is before us: with the exception of a few verses, describing the last moments of the lawgiver, &c., which were ascribed to Joshua. This tradition has for many a long century been almost universally adhered to. Not that there have not at different periods suspicions been raised respecting this 'authenticity.' The Pseudo-Clementines, for instance, assumed that the Law, orally delivered by Moses to the Elders, had, before and after its being committed to writing, undergone innumerable changes, nay, corruptions; among these the too personal and human conceptions of God, and the unworthy traits recorded of the Patriarchs. Jerome expresses himself in a somewhat doubtful manner on the relation of Ezra as the 'redactor,' or rather 'restorer,' of the Pentateuch. Aben Ezra boldly calls several passages later interpolations, and speaks of others still more poignantly as a *Saad*, or a 'Mystery,' i. e., as containing difficulties not to be cleared away in consonance with the common belief, which he, however, was too pious wantonly to disturb. Other voices, vaguely lifted up by more or less competent scholars, remained unheard. It was not until long after the Reformation, at the dawn of the exegetical and critical modern age, that the question whether this codex was the work of one man, or even of one age, and what share, if any, Moses had in its composition, began to be discussed seriously and on scientific grounds. Hobbes held that the Pentateuch was rather a work on, than by Moses, Spinoza came to the conclusion, that it was to Ezra that we were indebted for the

book in its present shape, and that it embodies certain genuine portions, collected at a late period, together with a vast amount of later material, added at various periods subsequent to the time of the supposed author.

Vitringa, Le Clerc (Clericus), Rich. Simon, and others, followed, resuming and enlarging the discussion chiefly respecting the difficulties which presented themselves in the accounts of the creation, and the like, contained in Genesis. The next, and indeed the most important step—because the one which at once removed the question from the field of hazy and timid speculations to that scientific basis upon which it still rests, was taken by Astruc, who, from the marked difference of the Divine names used in Genesis and the beginning of Exodus—noticed in the TALMUD and the FATHERS OF THE CHURCH—came to the conclusion, that these books had been worked up from different original documents, which he called Jehovistic and Elohistie respectively. See article GENESIS, where the development of this speculation is described. At the present stage of the investigation, the view very generally adopted is the ‘complementary theory,’ which assumes, with certainty, two or more authors—Jehovists and Elohist—for the whole of the first four books, at least; the fifth being by some (Delitzsch, Schulz, Kurz, &c.) still ascribed chiefly to Moses’s own hand. Only a small apologetic school, of which Hengstenberg long was spokesman, still upholds the entire integrity and authenticity of the work, pronouncing Moses its sole author. The contemporary discussions on these points, which, up to within a very recent period, were chiefly confined to Germany, have now also found their way into England. The impulse to the controversy in this country was principally given by Dr. Davidson, the ‘Essayists and Reviewers,’ and Bishop Colenso, all of whom, on the basis of these German investigations, raised some new points. Innumerable replies, by more or less competent champions, have been issued; but as yet, so far from either of the combatants having declared themselves convinced by the arguments from the other side, the controversy elicits new publications uninterruptedly.

While endeavoring to trace, in the briefest of outlines, some of the chief objections raised against the Mosaic authorship, and the replies given thereunto, we must remind the reader that ours is only the task of epitomizers, as it were, and that the very nature of our task precludes us from giving any opinion whatsoever about the superior force of the arguments on either side.

A work, alleged to be the production of one man, it is urged, first of all, ought to contain neither unnecessary repetitions of considerable length, nor contradictions, nor anachronisms. There ought to be a plan and a unity. Yet, there can be no doubt, they say, about the fragmentary character of the Pentateuch. Many portions, evidently complete in themselves, are strung together without the slightest logical sequence, nay, in an unchronological order. As to repetitions and contradictions, there is, to begin with, the very history of the creation, which occurs twice in the first chapters of Genesis, is each time given differently, and in each account the Divine name is consistently mentioned in a different way. The same is to be said with regard to the account of the Deluge, and several incidents in the lives of the Patriarchs; the important conversation between God and Moses respecting Aaron (Exod. iv. 10–16, and vi. 9); the descriptions of the tabernacle; the priestly vestments; the story of the manna as given in Exodus and Numbers; the account of the appointment of the council of the 70 elders in the same books; &c. Again, the work itself sometimes seems to indicate an author who is not the legislator himself, such as the phrase of Moses being the humblest of men; the account of his own death; the passage in Genesis ‘before there reigned any king over the children of Israel’ (xxxvi. 31); the occurrence of the name of the city of Dan (Gen. xiv. 14, Deut. xxxiv. 1), so called only after the conquest by that tribe. In Numb. xxxi. 34, again, we have an enumeration of a certain number of towns and villages built by the tribes of Gad and Reuben—an event which could not have happened during Moses’s lifetime; further, the frequent occurrence of the formula ‘unto this day’ (e. g., Deut. x. 8, where the author speaks of the institution of the Levites as being still in force ‘up to this day’), &c. It is contended, also, that the language of the Pentateuch varies very little from that of the last prophets, and that it can hardly be assumed that a thousand years should have made no perceptible difference in the idiom; more particularly has Deuteronomy been supposed to bear a striking resemblance, in style and language, to Jeremiah. The Pentateuch is further said to contain many facts palpably contradictory to natural laws, as they are established in the experience of the whole historical human race, and systematized by science.

Of the many ways to get rid of these and similar—old and new—exceptions, the most generally adopted is that which we mentioned as the method of ‘interpolation,’ by which the Apologetic School strikes out some fifty or more passages, as not belonging to the original work, but having crept in, by way of commentary note, or explanation, in post-Mosaic times—the body of the

work being thus saved, so to say, by a most extensive amputation. As to the argument from the language, it is said that the Pentateuch, being the divine book, by way of eminence, and embodying the very phrases (to the letter) made use of by the Almighty, must needs have served as a model for the next thousand years, and priests and Levites, the teachers of the people, were enjoined constantly to study and read it: hence the small difference in the later writers. Arabic and Syriac, it is argued, did likewise not change essentially for many centuries—an assertion, however, which only holds good if ‘many’ is taken in a very vague sense indeed. That Deuteronomy differs in style and manner, is verbose, &c., is explained by Moses’s advanced age. On the other hand, events which are not in harmony with the ‘natural laws,’ are accepted by the orthodox simply and literally as ‘miracles,’ while ‘conservative’ rationalists of the school of Eichhorn, Rosenmüller, and others who stand by the authenticity of the Pentateuch, have been at great pains to find some kind of poetical interpretation for them.

Some of the recent attacks on the authenticity are chiefly founded upon arithmetical grounds. The numbers of the people, their cattle, and the like, at various periods, do not seem to conform to the laws of natural increase, or even to the geometrical limits within which they were at times stated to have been confined. Among the direct proofs, however, proffered by the defenders of the authenticity, the following chiefly deserve attention. Deuteronomy, it is averred, can only be the work of Moses. He speaks in it to the men whom he has led for many years, as one who has lived through all the events himself.

There is no possibility of any one imitating the local coloring in such a manner. If, then, Deuteronomy must be allowed to be the work of Moses, the three preceding books, to the contents of which frequent allusion is made, must equally be supposed to be finally redacted, if not written, by the same hand; and it further follows naturally, that the introduction to these books, which is Genesis, must have emanated from it. Again, any one writing after Moses, could not possibly have possessed the extraordinarily correct knowledge of contemporary Egypt and Arabia, which appears throughout the Pentateuch. A writer who might be supposed to have acquired it by dint of study of antiquities, must, it is said, have betrayed himself on every page by inaccuracies and anachronisms. Nineveh is in Genesis a city of as yet little importance; while Resen, of which no trace is to be found in any other part of the Bible, is the great metropolis of Assyria of the time. Tyre, great in the days of David, and mentioned already in Joshua, is not to be met with in the Pentateuch, where a later writer would certainly have spoken of it in connection with Sidon. The Canaanite gods and altars are often spoken of; never their temples, of which yet we read in Joshua. Why, then, should that very ancient author, to whom must needs be traced the Pentateuch, not be Moses himself, rather than some contemporary of his? The fragmentary, abrupt, and, as it were, confused character of the work, the apologists further urge, so far from testifying against Moses, confirm the tradition of his authorship. Would not a later historian have worked the mixed mass of historical, geographical, legal, and personal material into a methodical and systematical whole? Who else could have imparted to the book the impress of a diary, so to say, but the man who was in the midst of the events, jotting down all the items important either in his own individual or the national career? And who but one standing in its very center could depict with such glowing colors the life that moved around him?—But a further direct argument for the authenticity is found by them in the very item of the language of the Pentateuch.

True, they say, it resembles as much as can be that of later books, because, as we said before, it remained the classical language for all later generations; but, on the other hand, it offers certain peculiarities—such as the use of a common pronoun of the third person singular for both the masculine and feminine genders; the same term for boy and girl; and the like archaisms—all of which distinctly prove it to be a work of a very much older date. The existence of an ancient Mosaic code of laws would further appear proved beyond any doubt by the constant recurrence of quotations from ‘the Law of Jehovah’ or ‘the Law of Moses’ throughout the other books of the Old Testament from Joshua to Hosea. Had there in reality been no such code in existence, the authors of the different biblical works could not possibly have so unanimously spoken of it without betraying a conscious forgery somewhere. That Ezra should have been the author, or, at all events, the refounder of the Pentateuch, is equally improbable, on account of the spirit, tone, language, and all those smaller peculiarities of which mention has been made; and he would, on the other hand, never have been able so skillfully to avoid his own individual manner and style, as it appears in his own book. The Samaritan P., it is further said, which, with a very few characteristic alterations, is an accurate transcript of our Pentateuch, would have been an utter impossibility, considering the hostile relations between the Samaritans and the

Jews, if it had not been well known as a genuine document before the division of the empire. That Hilkiah, who is said to have found the Book of the Law in the temple in the days of Josiah (2 Kings, xxii.; 2 Chron. xxxiv.) should have been its real author—an opinion first advanced by De Wette—would imply a complicity in the forgery not only on the part of Jeremiah, Huldah, and the elders, but almost of the whole people, among whom, on the contrary, there certainly seems to have been living a very vivid tradition of the former existence of the book or some of its portions at least. Moreover, had it been first written in those days, there surely would have been introduced some kind of prophetic allusion to the royal house of David, or, at all events, a pedigree and origin differing from the incestuous one given in Gen. xxxviii.

Deuteronomy would altogether have changed its language about Royalty (xvii. 15–20) very considerably; and Joseph's would not have stood out so prominently as a favored tribe. The alleged difficulties respecting the numbers are explained away more or less convincingly—in the most difficult cases, by miraculous interference. Corruptions, interpolations, and the many fates that befall ancient documents, are allowed to have crept in, in some places; although this argument is given up by those who hold that a special providence watched over the divine work. In all other respects, they hold these books are exactly as they were written by Moses under direct 'Inspiration'—thus far, in swiftest outlines, the pros and contras most commonly adduced, and worthy of some consideration.

A few rationalistic critics, however, have gone so far as to deny the very possibility of Moses having given the laws contained in the Pentateuch, chiefly founding their objections upon the ground that he was not likely to have been versed in the art of writing to an extent which the composition of these laws would presuppose. Egyptian characters, with which he might have been familiar, could not have been used for Hebrew composition; and the Hebrews themselves, uncultivated as they were, did not possess any characters of their own. There has only, in reply to these objections, that fact to be stated, that a soberer criticism of more recent date has found itself obliged, in deference to certain paleographical and other scientific truths, to give up most of these points, or, at all events, to found no such sweeping condemnation upon those which still remain. On the contrary, whichever of the hypotheses enumerated at the beginning is assumed, the groundwork of the legislation is traced back, by almost unanimous consent, to the historical person of Moses, who is no longer the mythical demigod of barbarous hordes, but a man. The final redaction of these laws—of which many of later date are found to be wholly inconsistent with the earlier corresponding laws—as of the whole of the Pentateuch, is almost as unanimously placed in ages long after him.

In the contemporary 'moderate' school in England, so far as we have been able to glean from their writings, the following seems to be the prevalent opinion on the point of the Mosaic authorship: It is allowed, that Moses did not write the whole of the Pentateuch, but portions of Exodus, Leviticus, and Numbers, and the whole of Deuteronomy, with the exception of the account of his death, and such portions as palpably show an author who points to the imminent dissolution of the empire. That even the fundamental Law (Decalogue) should be found in two varying versions, they hold, strengthens rather the assumption of their genuine Mosaic authorship in some original shape. The later editor, finding two different recensions made by contemporaries, or in subsequent ages, embodied them both, on account of their paramount importance, literally. Genesis was worked up from ancient documents, composed by various writers, living at various 'prehistoric' periods, either by Moses himself, or under his supervision, by some of the elders. The first redaction of the five books as a whole took place after the conquest of Canaan, through Joshua and the elders; the second and final redaction, however, in which it received its present shape, is to be dated from the time of Ezra, after the return from the exile.

The majority of continental modern critics of the more moderate stamp—who repudiate the notion of their belonging to the advanced rationalistic party—hold opinions of a very different kind; and since they have found professed partisans in England, the foremost of whom is Dr. Davidson, we will make use of his own words (*Introduction to the Old Testament*): 'There is little external evidence for the Mosaic authorship; and what little there is, does not stand the test of criticism. The succeeding writers of the Old Testament do not confirm it. The venerable authority of Christ himself has no proper bearing on the question. The objections derived from internal structure are conclusive against the Mosaic authorship. Various contradictions are irreconcilable. The traces of a later date are convincing. The narratives of the Pentateuch are usually trustworthy, though partly mythical and legendary. The miracles recorded were the exaggerations of a later age. The voice of God cannot, without profanity, be said to have externally uttered all the precepts attributed to him. Moses's

hand laid the foundation of the edifice of God's word, which has grown into the proportions in which we now possess it; but he was not the first writer who penned parts of the national legends and history. He was emphatically a *langviger*, not a historian, a grand spiritual actor in the life-drama of the Israelites, who founded their theocratic constitution under the direct guidance of the Supreme.'

A few words must be added respecting the use of the Pentateuch. According to Deut. xxxi. 24seqq., it was preserved in the Ark of the Covenant. Every seventh year it had to be read to the people in public; and probably the Schools of Prophets, instituted at the time of Samuel, propagated its use by copies. Moreover, certain priestly, sanitary, and other laws required constant reference to it, so that certain portions of it seem to have been widely in use at an early period. Every synagogue is, according to the traditional Law, to possess a roll of the Torah, written on parchment, and under certain strictly insisted-upon regulations, out of which roll certain portions are read on Sabbath and feast-days; and, according to the ancient custom in Palestine, when Monday and Thursday were the market-days—when the country-people came to town and the judges sat—also on those days. A smaller portion (Parasha) is read on these and on the afternoon service of the Sabbath than on the Sabbath morning service, when a whole Sidra is read, or rather chanted, according to the *Neginah*, which is note and accent at the same time. The Samaritans have, of all biblical books, only adopted the Pentateuch, with slight variations (see SAMARITANS), their Book of Joshua being a very different work from ours; and certain very recent accounts of their possessing also other adaptations of our biblical books, require confirmation. For the different translations of the Pentateuch, ancient and modern, see BIBLE. The first printed edition of the Pentateuch dates Bologna, 1482, fol. The name of commentators and writers on the whole of the Pentateuch, both in and out of the Church, is legion. We mention among the foremost, besides the Church Fathers (Augustine, Jerome, Ephraim, Syrus, &c.) and the medieval Jewish commentators (Raspi, D. Kimchi, Aben, Ezra), Calvin, Luther, Grotius, Père Simon, Le Clerc, Michaelis, Eichhorn, Jalm, De Wette, Kell, Hävernick, Bleek, Hengstenberg, Ranke, Kurtz, Sähelin, Ewald, Bertheau, Colenso, Graves, Stuart, Bush, &c.

PE'NTECOST (Gr. *pentecosté*, fiftieth) was the name given to the feast among the Jews, held on the fiftieth day after the pass-over, in celebration of the 'ingathering,' and in thanksgiving for the harvest. See FESTIVALS. From the Jewish use it was introduced into the Christian, and with special solemnity, as being the day of the descent of the Holy Ghost on the apostles, and of the first solemn preaching of the Christian religion. From very early times, pentecost has been regarded as one of the great festivals of the Christian year, and it was chosen as one of the times for the solemn administration of baptism; and the English name of the festival, *Whit-Sunday*, is derived from the *white* robes in which the newly-baptized were clad. It is regarded as specially sacred to the Third Person of the Blessed Trinity, to whose honor the services of the day are directly addressed. Many curious usages were anciently connected with the celebration. The dove, being held as an emblem of the Holy Ghost in some churches, a figure of a dove, suspended by a cord from the ceiling, was lowered so as to alight on the high altar during the service. In others, figures of cloven tongues, or red rose-leaves, were similarly introduced. The latter practice is said to be still retained at Messina, but in general these scenical representations have been discontinued. In some places however, in the East as well as in the West, the practice prevails of decorating the churches with evergreens and flowers, as is done in England at Christmas. The whole time intervening between Easter and Pentecost is celebrated in the Roman Catholic church with special solemnity, and with some peculiar usages, and of this something is retained in the Church of England.

PE'NTHOUSE, a projection forming an open roof or shed, protecting a doorway, gate, window, &c.

PENTLAND FIRTH, a channel or strait between the Atlantic and German Oceans, separating the mainland of Scotland from the Orkney Islands. It is 17 miles long, and from 6 to 8 miles wide. About a mile west of Duncansby Head is a ferry station, whence boats cross to Burwick, in the island of South Ronaldshay, a distance of 7 miles. The Pentland Skerries, 5 miles north-east of Duncansby Head, consist of two islets, and of several contiguous rocks. On the larger of the islets is a light-house with two lights, one of which is 170, and the other 140 feet above sea-level. The lat. of the light-house is 58° 41' N., long. 2° 55' W. Off the coast of Caithness, and separated from it by a channel called the Inner Sound (about two miles in width), is the island of Stromay; and 3 miles north-north-east of Stromay is the islet of Swona, one of the Orkneys. On the north side of Stromay is the small vortex or whirlpool of Swalchie, and west of it are the breakers called the 'Men of Mey,' which are supposed to be

produced by a current setting strongly on a concealed reef. The navigation of the P. F. is more dangerous than that of any other portion of the Scottish seas. A current setting from west to east flows through the Firth with a velocity of from 8 to 9 miles an hour, and causes numerous eddies and whirlpools. It is estimated that about 4000 vessels with cargoes pass through the Firth annually.

PENTLAND HILLS, in the Lowlands of Scotland, extend north-east from the border of Lanarkshire to the center of the county of Edinburgh, and to within 4 miles of the city of that name. The mean height is upwards of 1000 feet; the highest summit, Carnethy Cairn, in Edinburghshire, has an elevation of 1884 feet.

PENU'MBRA. When the shadow of an opaque object is thrown upon a surface at some little distance by a light of considerable apparent size, it is observed that the shadow is divided into two portions, a dark portion in the center, and a lighter portion surrounding it. The former is known as the *umbra*, or complete shadow; the latter as the *penumbra*, or partial shadow. A

reference to the figure will at once make plain their origin and relation; for if S be the illuminating body, E the object whose shadow is cast on the surface, ABCD, it is seen that the small portion, *uu*, receives (omitting all consideration of refraction, dispersion, &c., of light) no light from S, while the whole surface outside of PPPP' is completely illuminated. The point P' receives light from the whole of S; the point F is only half illuminated, and that by the lower part of S, the illumination of the points becoming less and less as they approach *u'*, which is unilluminated. The portion within *uu'* is the umbra and that between the boundaries PPPP' and *uu'* is the penumbra, which, as we have seen, gradually shades from perfect light at the outer boundary to perfect darkness at the inner, so that it is almost impossible exactly to note its limits on either side. This phenomenon, it is evident, can only occur when the illuminating body is of such a size, real or apparent, as to make the angle, P'Ku', of sensible magnitude; and it is equally evident that the nearer the body E approaches the plane on which its shadow is cast, the larger is the umbra and the smaller the penumbra; while by increasing the distance between E and the plane, so that the point L shall fall between them, the umbra is made to vanish, and the penumbra is increased. This is well illustrated by natural phenomena: the shadow of a man cast by the sun on the ground presents almost no penumbra; the shadow of the earth thrown by the sun upon space at the distance of the moon gives a penumbra many times as large as the umbra; and sometimes, when the moon is new at her apogee, for instance, her shadow cast upon the earth exhibits no umbra. Spectators on the earth who see a partial eclipse of the sun, are situated within the penumbra, but within the umbra when they observe a total eclipse; while if the eclipse be annular, the umbra does not exist in the shadow cast by the moon on the earth's surface. See ECLIPSES.

PE'NZÁ, a central government of European Russia, between the government of Nijni-Novgorod on the north, and that of Tambov on the west. Area, 15,000 sq. m.; pop. (1879) 1,332,598. The surface is in extensive and elevated plains, marked occasionally with ridges of low hills. The rivers are tributaries of the Don and Volga, and three of them, the Khoper, the Soura, and the Moksha, are navigable. The climate, though rather cold in winter, is temperate, agreeable, and healthy. The soil, consisting for the most part, of black earth, is extremely fertile, and agriculture is the principal employment of the inhabitants. Grain of different kinds, leguminous plants, beet-root, flax, hemp, tobacco, and hops are the principal products. Much of the grain is used in the numerous distilleries, and considerable quantities of it are exported to the neighboring governments. About one-third of the entire area is covered with forests, some of which consist entirely of oak-trees. The manufactories are centered chiefly in the towns; cloth and leather are the principal articles made. The commercial improvement of the government is hindered by the want of direct means of communication with the consuming districts. The principal towns are Penza, Mokshansk, and Saransk.

PENZA, a town of European Russia, capital of the government of the same name, on the Soura, 220 miles south-south-east of Nijni-Novgorod. It was founded in the middle of the 17th c., as a defence against Tartar invasion, is a handsome town, occupying an elevation, and containing 19 churches, 2 convents, many gardens, a large park, with a beautiful fruit-garden and a horticultural school. It possesses cloth-factories, iron-works, tanneries, soap-boiling and candle-making establishments. The principal articles of commerce are corn and timber, which is floated down the Soura during Spring. Pop. (1880) 35,000.

PENZA'NCE, a market and sea-port town, and a municipal borough of England, in the county of Cornwall, stands on the north-west shore of Mount's Bay, 22 miles west-south-west of Falmouth. It is the most westerly town in England—the light-house on its pier being in lat. 50° 7' N., and in long. 5° 28' W. The town, standing on a finely-curved shore, surrounded by rocky eminences, and in a fertile district, is exceedingly picturesque in situation, and is famous for its mild, though somewhat moist climate. Its esplanade, one of the finest in the west of England, commands charming land and sea views. The chief buildings, most of which are constructed of granite, are the town-hall and corn-market, surmounted by a dome, and the chapels of St. Paul and St. Mary. There are numerous boarding-houses for the accommodation of the visitors, attracted hither by the temperate and equable climate, by the beauty of the neighboring scenery, and the curiosities of the district of Land's End. Woollen yarns and cloths are manufactured; the fishery employs upwards of 2000 persons; agricultural produce, pitchblende, and tin and copper ores produced from the mines of the vicinity are exported; and timber, iron, hemp, and hides are the chief imports. The harbor is accessible for vessels of considerable burden, and is furnished with a pier 800 feet in length. In 1880, 789 vessels, of 65,671 tons, entered the port, and 738, of 59,261 tons, cleared it. Pop. (1871) 10,414; (1881) 11,684. P. was laid in ashes by a party of marauding Spaniards in 1595, and was sacked by Fairfax in 1646. At P. is a statue to Sir Humphry Davy.

PE'ON. See CALOPHYLLUM.

PEO'RIA, a city and port of entry in Illinois, U.S., on the west bank of the Illinois River, which is crossed by two bridges of 2500 feet, at the outlet of Peoria Lake, 70 miles north of Springfield, and 160 miles south-west of Chicago. It is connected by steamboat navigation with the Ohio and Mississippi, by canal with Lake Michigan, and is an important station on the great network of western railways. Bluffs of bituminous coal, opening upon the river banks, supply numerous manufactories. There are 28 churches, and numerous schools and public institutions. Pop. (1870) 22,849; (1880) 55,419.

PEPE. Three Neapolitans of this name have played an important part in history. The first of these was GABRIELE PEPE, who was born in 1781 at Bojano, in the present province of Molise, Italy, and was a student of law in 1799, when, on the proclamation of the Parthenopean Republic, he took service in the Franco-Neapolitan army, and was consequently exiled on the fall of the new government. Subsequently he served in the Italian legion in the French army under King Joseph in Spain with great distinction, and with Murat. In 1815, he was raised by the latter to the rank of colonel, a grade confirmed by Ferdinand I., who gave him the command of a province, and afterwards of the garrison of Syracuse. He espoused with great zeal the cause of the revolutionary party in 1820, and was deputed to the national parliament. On the downfall of the constitutional government, he was seized by the Austrians, and imprisoned at Olmutz, in Moravia; but was released at the end of two years, and retired to Tuscany; where, feeling hurt at some remarks of M. de Lamarine, then charge-d'affaires in that country, on Italian patriotism, he in turn wielded the pen in defence of his countrymen with such severity that a duel resulted between him and the poet, followed by an apology from the latter. From this time he took no part in political affairs, but devoted himself to science and literature, and died at Bojano, August 1849.—His cousin, GUGLIELMO PEPE, born in 1782 at Squillace, was a man of equal note. After serving in the French army of Catalonia, and attaining to high rank and honor, he returned to Naples to support Murat; and after the flight of that chief, was one of the leaders of the 'Muratist' party, yet, after the restoration, the Bourbon Ferdinand allowed him to retain his honors. P. rendered valuable services in routing out (1818) the nests of brigands who infested the provinces of Avellino and Foggia, and after the insurrection of 1820, was for some months the most influential man in Naples; but, after his defeat by the Austrians at Rieti, 7th March 1821, he was forced to flee the country, and took refuge in Spain, whence he retired to England, where he lived many years, afterwards removing to Paris.

In 1848, on the proclamation of an armistice, he returned to Naples, welcomed with enthusiasm by the people and the court; and the king, constrained by the public voice, gave him the com-

mand of the Neapolitan contingent which was sent to aid the Lombards against Austria; but after the suppression of revolution in Naples (15th May), P., was ordered to return and put down the insurgents of Calabria. Disregarding these orders, P., with as many of the Neapolitans as would adhere to him (2000 men), devoted his energies to the defence of Venice, of whose army he had been elected commander-in-chief. His prudence and courage, joined to an untiring energy, enabled him greatly to retard the operations of the Austrians; but the force under his command was ill suited for effecting anything of importance. His most remarkable exploit was the sortie he effected in person (October 1849) from the citadel of Marghera. After the fall of Venice, P. fled to Corfu on board a French ship, and subsequently returned to Paris. He had, however, an antipathy to France, and speedily removed to Turin, where he died 9th August 1855. He has left several works, the chief of which are, *Relation des Evénements Politiques et Militaires de Naples en 1820 et 1821* (Paris 1822, in Italian and French), and *Histoire des Révolutions et des Guerres d'Italie en 1847, 1848, et 1849* (Paris, 1850). A statue of him has been erected in Turin.—His elder brother, FLORESTANO P. (born 1780, died 1851), was also a Muratist, but submitted to Ferdinand. He was a mild and conciliatory, but feeble liberal.

PEPERINO, an Italian term, applied by some geologists to the brown volcanic tuffs derived from augitic rocks, to distinguish them from the ordinary tufas, which name they confine to the lighter-colored pumiceous rocks that have more trachyte in their composition.

PEPIN, the name of several distinguished members of the Carolingian family; the first of whom in order was PEPIN LE VIEUX or PEPIN DE LANDEN, the founder of the family. He was of a Brabant family, and took his designation from Landen (now in Liege, Belgium). Rebelling with others of the great lords of Austrasia against the rule of Brunehaut, who was regent for the youthful king, he offered the crown to Clotaire II., king of Neustria, who, in reward of his services, created P. *maire du palais* of Austrasia, an office which he continued to hold during the two following reigns, and died in 639. His administration was directed to the preservation of the power and integrity of the Austrasian kingdom, and though, by opposing the various schemes of centralization proposed by the king, he fell under the royal displeasure, his conduct gained for him favor and influence with the Austrasian chiefs; his power and wealth were greatly increased, and a broad and firm path to political supremacy laid for his descendants. His son, Grimoald, who succeeded him as *maire du palais*, incautiously attempted to gather the fruits of his father's schemes before they were quite ripe, and accordingly suffered for his folly. Both he and his son Childbert were strangled in prison (656) by order of Clovis II. Pepin 'the Old' left by his daughter a grandson, PEPIN LE GROS or PEPIN D'HERISTAL, who was elected by the Austrasian nobility as their chief, to protect Austrasia against the machinations of Elroin, the able *maire* of Neustria. His first step was to rid himself of the Merovingian king, who nominally ruled over Austrasia; which was effected by obtaining the condemnation of the unfortunate monarch, Dagobert II., by a council of bishops, and then putting him to death. From this time the Merovingian rule in Austrasia ceased. P. was now sole ruler, but his ambition did not stop here; he had resolved on the ruin of the Merovingian monarchs, and accordingly levied a large army for the invasion of Neustria. Elroin, on his side, was equally resolved to humble the territorial aristocracy, and support the throne; and advancing into Austrasia, his army came in sight of P.'s at Loixi. In the battle (680) which ensued, P.'s army was totally defeated, his brother and co-ruler, Martin, was taken prisoner and put to death, and he himself narrowly escaped.

Luckily for him, however, Elroin was soon afterwards assassinated, and his successor, Warato, signed a treaty of peace. The incapacity and tyranny of Warato and his successor, Berthaire, discontented the Neustrian nobles, who went over to P., and by this accession of power enabled him to resume the offensive. Neustria was immediately invaded, and a bloody but decisive battle at Testry (687) freed P. of his opponent Berthaire, who was left dead on the field, and placed Neustria at his feet. Full of moderation in the midst of triumph, and satisfied that he could not place on the throne a more obedient slave than Thierry III., the then king of Neustria, P. caused him to be also proclaimed king of Austrasia, but reserved for himself the sovereign power, wielding the sceptre though declining the crown. From this time he ruled the whole of France (Austrasia in his own right by his election as Duke, and Neustria as *maire du palais*) with energy, and undisturbed by any internal commotion, during the lives of three other 'faineant' kings, till his death in 714. He had made several campaigns (689—708) against the Frisians, but that valiant and independent race was not thoroughly subdued for some time afterwards. P. had two legitimate sons who died before him, and an illegitimate son, Charles, subsequently known as Charles

Martel (q. v.), who succeeded to his power.—The third who bore this name was PEPIN LE BREF, the younger son of Charles Martel, who, on the death of his father in 741, received Neustria and Burgundy; Austrasia, Thuringia, and Suabia being the heritage of his elder brother Carloman. Aquitaine was nominally a part of P.'s dominions, though, as it was really independent under its own duke, he made several attempts to subdue it; but the duke was quite able to hold his own against both P. on the one hand and the Arabs (from Spain) on the other. The farce of governing the country in the name and as the chief minister of the Merovingian sovereign was still kept up, though P. was eagerly longing for an opportunity to assume the crown; but the present time was inopportune, as no sooner was the restraint of Charles Martel's iron hand removed by death, than revolts broke out in all quarters among the Franks, Germans, Bavarians, and Gascons.

The country, by the united exertions of P. and Carloman, was restored to tranquillity about 745. Those princes who had excited the insurrection were mostly deposed, and otherwise punished, and the Duke of Aquitaine was compelled to acknowledge at least the nominal sovereignty of Pepin. In 747, Carloman bade adieu to power, and retired into a convent, leaving his government to his sons, who were immediately dispossessed by Pepin. After crushing a rebellion of Saxons and Bavarians, P. began to carry out his favorite project of dispossessing the Merovingian dynasty of even the semblance of authority, and of originating in person a new royal dynasty. To gain his point he flattered the clergy, then the most influential body in France; and as they had been despoiled by Charles Martel for the behoof of his warriors, a moderate degree of kindness and generosity on the part of P. contrasted him so favorably with his father, that the clergy at once became his partisans. So did the pope, who felt the importance of securing the aid of the powerful Frankish chief against the Lombards, who were then masters of Italy, and released the Franks from their oath of fidelity to Childeric, the Merovingian monarch. On learning this, P. at once caused himself to be elected king by the assembly of estates at Soissons, and was consecrated by the Bishop of Mayence (March 752). Childeric retired to a convent, where he died in 755. P. was the first Frankish monarch whose election received the sanction of the pope, and who was consecrated to his high dignity; and these solemn ceremonies put the crown to a great extent at the mercy of the clergy, who from this time took a political rank in the state. The practice, too, followed by P. and his predecessors in office, of gaining partisans, by granting particular fiefs to various chiefs, greatly strengthened the feudal system, and proportionally weakened the royal power. This effect, however, did not show itself till after the subsequent reign of Charlemagne, on account of the personal genius of these two rulers. P. was soon called upon to aid the pope against the Lombards, and marching into Italy at the head of a large army, he compelled Astulf, the Lombard king, to retire from the siege of Rome, and restore several cities which had previously belonged to the Greeks; these were now handed over to the pope. He had hardly returned to France, when he was anew summoned (755) to Italy, the Lombards having broken their engagements.

This time he took Ravenna, Emilia, the Pentapolis, and the duchy of Rome from the Lombards, reuniting them to the Holy See. After the settlement of affairs in Italy, the turbulent nations on his eastern frontier demanded his attention. The Saxons and other German tribes were defeated (757), their country cruelly ravaged, a heavy tribute exacted, and numbers of captives and hostages taken. Resolved to unite the whole of Gaul under his authority, he eagerly accepted the invitation of the Visigoths of Septimania to aid them against the Arabs, who had taken possession of the country; and after a war of many years' duration, Narbonne, the last of the Arab strongholds, was taken, and the country freed of these invaders, at once acknowledged P.'s authority. The remaining years of his reign were occupied in reducing the independent monarchy of Aquitaine, which was not accomplished till, after nine years (760—768) of desolating warfare. P. obtained the assassination of his opponent, Duke Waifre, whose partisans then laid down their arms, surrendering to the Frankish monarch the vast provinces which stretch from the Loire to the ocean and the Pyrenees. Shortly after this conquest, P. died of dropsy, September 768. He was a most active, enterprising, and in general fortunate prince; he established the unity of the Gallic nation, and protected it as far as could be done by invading and ravaging the territories of the neighboring nations, though he also introduced those elements of weakness into its constitution, which reduced the authority of his successors to such a deplorable state. The others of this name, though important personages at the time, make little figure in history.

PEPPER (*Piper*), a genus of plants of the natural order *Piperaceæ* (q. v.), which once included the whole of that order; but, as now limited, consists of plants with woody stems, solitary spikes opposite to the leaves, and covered with flowers on all sides, the flowers mostly hermaphrodite.

The most important species is COMMON P. or BLACK P. (*P. nigrum*), a native of the East Indies, now cultivated also in many tropical countries, and extensively in some parts of the New World; its fruit being the most common and largely used of all spices. It is a rambling and climbing shrub, with smooth and spongy stems, sometimes twelve feet in length; and broadly ovate, acuminate, leathery leaves. The fruit is about the size of a pea, of a bright-red color when ripe, not crowded on the spike. In cultivation, the P. plant is supported by poles, or by small trees planted for the purpose, as it loves a certain degree of shade, and different kinds of trees are often planted for this purpose in India. It is propagated by cuttings, comes into bearing in three or four years after it is planted, and yields two crops annually for about twelve years. When any of the 'berries' of a spike begin to change from green to red, all are gathered, as when more fully ripe they are less pungent, besides being apt to drop off. They are spread on mats and separated from the spikes by rubbing with the hands or by treading with the feet, after which they are cleaned by winnowing. The *Black P.* of commerce consists of the berries thus dried, and become wrinkled and black; *White P.* is the seed freed from the skin and fleshy part of the fruit, to effect which the dried fruit is soaked in water and then rubbed. *White P.* thus prepared is of a whitish-gray color, but not unfrequently undergoes a bleaching by chlorine, which improves its appearance at the expense of its quality. *Black P.* is much more pungent than *White P.*, the essential constituents of the spice being more abundant in the outer parts of the fruit than in the seed. *P.* depends for its properties chiefly on an acrid resin and an acrid volatile oil; it contains also a crystalline substance called *Piperin*.

The fruit of *Piper trilocum*, a species very similar to the *Common P.*, is more pungent; and it is cultivated in some parts of India.—The fruit of other species of *Piperaceæ* is used as pepper in their native countries; that of *Cocobryon Capense* at the Cape of Good Hope; that of *Peltobryon longifolium*, of *Artanthe crocata*, of *A. trichostachya*, and of *Serronia jaborandi* in South America.—*Chavica Roxburghii* and *C. officinarum* yield the LONG PEPPER of druggists. They have woody climbing stems, solitary spikes opposite to the leaves, diœcious flowers, and the fruits so close together on the spikes as in ripening to become a compact mass. The spikes are gathered when unripe, and dried in the sun. They are used in pickling and for culinary purposes, also in medicine for the same purposes as *Common Pepper*. They are generally reputed to be more pungent than *Common Pepper*. *C. Roxburghii* is cultivated in Bengal and the Circars, where it is called *Pippul*; *C. officinarum* in the Dutch East Indian colonies. The root and thickest part of the stem of *C. Roxburghii* are extensively used in India as a stimulant medicine; and are cut into small pieces, dried, and brought to the market under the name of *pippula moola*.

P. acts on the skin as a rubefacient and vesicant, and is often used for this purpose in a powdered state, moistened with some kind of alcoholic spirit. It is also employed as a local stimulant in relaxation of the uvula, and is applied in the form of an ointment to ringworm. Taken into the stomach in small quantities it is a pleasant stimulant, but in large doses it produces great pain and irritation. The quantity used, however, by the natives of hot climates much exceeds anything known among Europeans, and the effects are evidently beneficial rather than injurious. The chief use of *P.* is as a spice and condiment.

P. was known to the ancients; Hippocrates employed it as a medicine; and Pliny expresses his surprise that it should have come into general use, considering its want of flavor. In the middle ages *P.* was one of the most costly spices, and in the 13th c. a few pounds of it were reckoned a princely present. The quantity now imported into Europe is immense; but there are no means of exactly ascertaining how much of the *P.* of commerce is the produce of *Piper nigrum*, or indeed of the *Piperaceæ*, and how much—although certainly it is not a large proportion of the whole—is the produce of species of *Capsicum*.

The name *P.* is popularly given to substances possessing a pungency resembling that of *P.*, although produced by very different plants. Thus, CAYENNE *P.* is the produce of species of *Capsicum*, of the natural order *Solanaceæ*; JAMAICA *P.* (or PIMENTO) of species of *Eugenia*, of the natural order *Myrtaceæ*; and GUINEA *P.*, or MELEGUETTA *P.*, of species of the natural orders *Scitamineæ* and *Anonaceæ*. See CAPSICUM, PIMENTO, GRAINS OF PARADISE, and GUINEA PEPPER.

PEPPERMINT. See MINT.

PEPPER-POT, a celebrated West Indian dish, of which Casareep (q. v.) is a principal ingredient; and along with it flesh or dried fish, vegetables, chiefly the unripe pods of the ochro (see HIBISCUS), and chillies (see CAPSICUM).

PEPPER-ROOT (*Dentaria diphylla*), a perennial herbaceous plant, of the natural order *Crucoifera*, a native of North America, with pairs of ternate leaves, and racemes of white flowers; the

root of which has a pungent mustard-like taste, and is used as a condiment.

PEPSINE has been already described (in the article DIGESTION) as one of the essential constituents of the gastric juice. Various modes of extracting it from the walls of the stomach of the calf, sheep, and pig have been proposed by different chemists (Wasmann, Frerichs, Schmidt, Boudault, and others), into which it is unnecessary to enter. According to Schmidt's analysis, it contains 53.0 per cent. of carbon, 6.7 of hydrogen, 17.8 of nitrogen, and 22.5 of oxygen, and hence in its ultimate composition it is closely allied to albumen. This substance, either as a powder or in solution, has been employed of late years to a considerable extent in medical practice, in cases of disordered digestion from deficient or imperfect secretion of gastric juice, and of convalescence from typhoid and other debilitating fevers. Pepsine wine is perhaps the best form in which to prescribe this substance; a teaspoonful being the ordinary dose.

PEPYS, SAMUEL, a distinguished officer of the Admiralty during the reign of Charles II. and James II., was born February 23, 1632—1633. He was the son of a London citizen, a tailor, but was well educated, first at St. Paul's School, and afterwards at Magdalen College, Cambridge. His cousin, Sir Edward Montagu (the first Earl of Sandwich), introduced him to public employment. In 1660 he was appointed Clerk of the Acts of the Navy, and in 1673 Secretary for the affairs of the Navy. He was an excellent public servant, acute, diligent, and laborious; but during the fanatical excitement of the Popish Plot he was committed to the Tower, on an unfounded and absurd charge of aiding in the design to dethrone the king and extirpate the Protestant religion. Having been discharged without a trial, *P.* was replaced at his post in the Admiralty, which he retained till the abdication of James II. For two years he held the honorable station of President of the Royal Society. He died May 26, 1703. *P.* wrote *Memoirs of the Royal Navy*, 1690. He left to the Magdalen College his large collection of books, MSS., and prints, including about 2000 ancient English ballads, forming five folio volumes. This curious collection was begun, he says, by Seiden, and continued down to the year 1700, when the form peculiar to the old ballads, namely, the black letter with pictures, was laid aside for the simpler modern fashion. *P.* is now best remembered for his *Diary*, deciphered by the Rev. J. Smith from the original shorthand MS. in the Pepysian Library, Cambridge, and first published, under the editorial care of Lord Braybrooke, in 1825. It commences on the 1st of January 1659—1660, and is continued for above nine years, when the diarist was obliged from defective eyesight to abandon his daily task. As a picture of the court and times of Charles II. this *Diary* is invaluable; the events, characters, follies, vices, and peculiarities of the age are presented in true and lively colors, and the work altogether is one of the most rare, unique, and amusing books in the language. Bright's edition (1875—80) is in 6 vols. See Wheatley's *P. and the World he lived in* (1880).

PE'RA, a suburb of CONSTANTINOPLE (q. v.).

PERAK, one of the largest Malay states in the peninsula of Malacca, extends about 90 miles along the Strait of Malacca, and some 45 miles inland. The soil is fertile, and for the most part covered with luxuriant vegetation. The mineral wealth is very great, and comprises abundance of tin, some gold and plumbago, and poor coal. Elephants, tigers, leopards, bears, and boars, and occasionally a rhinoceros, are found. *P.* is thinly inhabited by various races, of whom the Malays are the most numerous. Some of the others are of the same stock as the inhabitants of Sumatra; there are wild hill-tribes in the interior. Cannibalism is still practised by some of these races. *P.* is governed by a sultan and petty chiefs, who have of late come under British influence, represented by a Resident and his assistants. The murder of the British Resident in 1875 has made the name of *P.* more familiar to Englishmen. See Major McNair's *P. and the Malays* (1877).

PERAMBULATION OF PARISHES. The ancient custom in England of perambulating parishes in Rogation week had a twofold object. It was designed to supplicate the Divine blessing on the fruits of the earth; and to preserve in all classes of the community a correct knowledge of, and due respect for, the bounds of parochial and individual property. It appears to have been derived from a still older custom among the ancient Romans, called *Terminalia*, and *Ambarvalia*, which were festivals in honor of the god *Terminus* and the goddess *Ceres*. On its becoming a Christian custom the heathen rites and ceremonies were of course discarded, and those of Christianity substituted. It was appointed to be observed on one of the Rogation (q. v.) days, which were the three days next before Ascension Day. Before the Reformation parochial perambulations were conducted with great ceremony. The lord of the manor, with a large banner, priests in surplices and with crosses, and other persons with handbells, banners and staves, followed by most of the parishioners,

walked in procession round the parish, stopping at crosses, forming crosses on the ground, 'saying or singing gospels to the corn,' and allowing 'drinkings and good cheer' (Grindal's *Remains*, pp. 141, 241, and *Note*; Whitgift's Works, iii. 266—267; Tindal's Works, iii. 62, 234, Parker Society's Edition), which was remarkable, as the Rogation days were appointed fasts. From the different practices observed on the occasion the custom received the various names of *processioning*, *rogationing*, *perambulating*, and *ganging the boundaries*; and the week in which it was observed was called *Rogation week*; *Cross week*, because crosses were borne in the processions; and *Grass week*, because the Rogation days being fasts, vegetables formed the chief portion of diet.

At the Reformation, the ceremonies and practices deemed objectionable were abolished, and only 'the useful and harmless part of the custom retained.' Yet its observance was considered so desirable, that a homily was prepared for the occasion; and injunctions were issued requiring that for 'the perambulation of the circuits of parishes, the people should once in the year, at the time accustomed, with the rector, vicar, or curate, and the substantial men of the parish, walk about the parishes, as they were accustomed, and at their return to the church make their common prayer. And the curate, in their said common perambulations, was at certain convenient places to admonish the people to give thanks to God (while beholding of his benefits), and for the increase and abundance of his fruits upon the face of the earth, with the saying of the 103d Psalm. At which time also the said minister was required to inculcate these, or such like sentences, Cursed be he which translateth the bounds and doles of his neighbor; or such other order of prayers as should be lawfully appointed.' (Burn's *Ecclesiastical Law*, vol. iii. 61.)

To this day, questions of disputed boundary between parishes are invariably settled by the evidence afforded by these perambulations; for in such questions, immemorial custom is conclusive. And so far are they recognized in law, that the parishioners on such occasions are entitled to trespass on lands, and even to enter private houses if these stand on the boundary line. In Scotland, where the parochial principle has never been developed as in England, there seem to be few traces of a similar practice. But, as between neighboring landowners, a brief of perambulation is the technical remedy for setting right a dispute as to boundaries or marches; and perambulating or 'riding' the bounds of boroughs is a common practice.

The necessity or determination to perambulate along the old track often occasioned curious incidents. If a canal had been cut through the boundary of a parish, it was deemed necessary that some of the parishioners should pass through the water. Where a river formed part of the boundary line, the procession either passed along it in boats, or some of the party stripped and swam along it, or boys were thrown into it at customary places. If a house had been erected on the boundary line, the procession claimed the right to pass through it. A house in Buckinghamshire, still existing, has an oven passing over the boundary line. It was customary in the perambulations to put a boy into this recess to preserve the integrity of the boundary line.

At various parts of the parish boundaries, two or three of the village boys were 'bumped'—that is, a certain part of the person was swung against a stone wall, a tree, a post, or any other hard object which happened to be near the parish boundary. This, it will scarcely be doubted, was an effectual method of recording the boundaries in the memory of these *battering-rams*, and of those who witnessed this curious mode of registration.

The custom of perambulating parishes continued in some parts of the kingdom to a late period, but the religious portion of it was generally, if not universally omitted. The custom has, however, of late years been revived in its integrity in many parishes.

PERCEPTION. This word refers to our reception of knowledge through the senses, an operation that to the common understanding seems simple enough, but, viewed philosophically, is attended with much difficulty. Perception, considered as a source of knowledge, refers exclusively to the outer, or the object world—the world of extended matter and its properties. The names for the act of knowing one's own mind—the feelings and thoughts of the individual—are Self-consciousness and Self-inspection. The word 'consciousness,' is sometimes improperly limited to this signification. Locke used the term 'Reflection' for the same meaning, but this is ambiguous, and is now disused. All our knowledge is thus said (by those that deny innate ideas) to spring from two sources—Perception and Self-consciousness.

Two great disputes connect themselves with Perception, both raised into their full prominence in the philosophical world by Bishop Berkeley. The first is the origin of our judgments of the Distances and real Magnitudes of visible bodies. In opposition to the common opinion on this subject, Berkeley maintained that these were learned by experience, and not known by the mere act of vision. See VISION.

The second question relates to the grounds we have for asserting the existence of an external and material world, which, in the view of Berkeley was bound up with the other. Inasmuch as perception is a mental act, and knowledge is something contained in a mind, what reason have we for believing in the existence of objects apart from our minds? or what is the mode of existence of the so-called external world?

The following sentences show in what manner Berkeley opened up the question: 'That neither our thoughts, nor passions, nor ideas, formed by the imagination, exist without the mind, is what everybody will allow; and it seems no less evident that the various sensations or ideas imprinted on the sense, however blended or combined together (i. e., whatever objects they compose), cannot exist otherwise than in a mind perceiving them. I think an intuitive knowledge may be obtained of this by any one that shall attend to what is meant by the term *exist* when applied to sensible things. The table I write on, I say, exists—i. e., I see and feel it; and if I were out of my study, I should say it existed, meaning thereby that if I was in my study I might perceive it, or that some other spirit actually does perceive it. There was an odor—i. e., it was smelled; there was a sound—that is to say, it was heard; a color or figure, and it was perceived by sight or touch. This is all I can understand by these and the like expressions. For as to what is said of the absolute existence of unthinking things, without any relation to their being perceived, that seems perfectly unintelligible. Their *esse* is *percipi*, nor is it possible they should have any existence out of the minds or thinking things which perceive them.'

This doctrine of Berkeley, amounting, it was said, to a denial of the existence of a material world (which is far from a correct view of it), was followed up by Hume, who, on similar reasoning, denied the existence of mind, and resolved the universe into a mere flow of ideas and impressions without any subject to be impressed, acknowledging, nevertheless, that he felt himself unable, practically, to acquiesce in his own unanswerable arguments. There was obviously some great mistake in a mode of reasoning that brought about a dead-lock of this description; and hence it has been the work of *metaphysical* philosophy since that time to endeavor to put the perception of the world on an admissible footing.

Dr. Reid reclaimed against Berkeley and Hume, by appealing to Common Sense, or Unreasoning Instinct, as a sufficient foundation for our belief in the existence of a world apart from our own minds. Sir W. Hamilton has expounded the same view with greater clearness and precision. He considers that our consciousness tells us at once that in the act of perceiving there is both a *perceiving subject*—self, or the mind—and an *external reality*, in relation with sense, as the *object perceived*. 'Of the existence of both these things,' he says, 'I am convinced; because I am conscious of knowing each of them, not mediately in something else, as *represented*, but immediately in itself, as *existing*. Of their mutual dependence I am no less convinced; because each is apprehended equally and at once, in the same indivisible energy, the one not preceding or determining the other, not following or determined; and because each is apprehended out of, and in direct contrast to the other.'—*Reid*, p. 747.

Much as Hamilton has labored to elucidate this doctrine in all its bearings, it has not been universally accepted as satisfactory. Many believe that he has regarded as an ultimate fact of our constitution what admits of being still further resolved, and has mistaken an acquisition of the mature mind for a primitive or instinctive revelation.

Professor Ferrier, in his *Institutes of Metaphysic*, has gone through the question with extraordinary minuteness and elaboration. His main position is the inseparability of the subject and the object in perception (a position also maintained by Hamilton in the above extract), which is not reconcilable with the common assumption as to the independent existence of matter. Indeed, he reduces the received dogma of the existence of matter *per se* to a self-contradiction, and builds up a system in strict conformity with the correlation, or necessary connection, of the mind perceiving with the object perceived. He thus approaches nearer to Berkeley than to Hamilton or to Reid.

Those who would endeavor to show that our notion of the outer world is a complex fact, and an acquisition, and not a simple apprehension of the uneducated mind, explain themselves to the following effect. It is in the exercise of *force* that we have to look for the peculiar feeling of the externality of sensible things, or the distinction that we make between what impresses from without, and impressions not recognized as outward. Any impression that rouses a stroke of energy within us, and that varies exactly and constantly as that energy varies, we call an outward impression. Dr. Johnson refuted Berkeley, as he thought, by kicking a stone. But in fact it was his own action with its consequences, and not the optical impression of a stone in the eye, that satisfied him as to the existence of something outward. The sum-total of all the occasions for putting forth

active energy, or for conceiving this as possible to be put forth, is our external world.

We experience certain uniformly recurring sensations, and certain uniform changes in these, when we exert particular energies. Thus the visible picture of our dwelling in a permanent and habitual experience, and the variations of appearance that it is subject to correspond principally to our own conscious movements. As we move from one end of a room to another, we experience a change of the visible aspect at every step, and this regularly happens as often as we repeat the movement. But at times the appearance exists in another shape, to which we give the name of memory or *idea*. We draw a marked distinction between these two modes of presentation, the actual and the ideal, and we assign a superiority to the one over the other. The superiority we find connects itself with the relation to our own movements; a mere idea or mental picture remains the same whatever be our bodily position or bodily exertions; the sensation that we call the *actual* is entirely at the mercy of our movements, shifting in every possible way (but uniformly) according to the varieties of action that we go through.

With a forward movement the visible impression enlarges, with a backward movement it diminishes. A certain movement of the eye shuts it out, another restores it. The raising of the head and the bending of the body are followed by an altered spectacle. We cannot but draw a broad distinction between the mental scenery that is thus shifted by all our movements, and the ideas and dreams that vary of themselves while we are still. To express the one fact, we use the terms externality, the material world, independent existence; to express the other we employ the opposite language, internality, the world of mind, &c. Even if sensation were only in ourselves, we should still have to distinguish between present sensation and remembered or revived sensation, the reference of the one to our voluntary movements, and of the other to no such modifying causes, would oblige us to note a vital difference in the two classes of facts. Such is the uniformity of connection between certain appearances and certain movements, that we come to anticipate the one through the other. We know that in some one position, as when lying in bed, certain movements of the limbs and back will bring us to the sensation of a solid contact in the feet; that another series of movements will bring on a particular view to the sight; that a third movement will give the sound of a bell in the ear, and so forth. We cannot avoid regarding those various sensible effects, brought uniformly into play by a regular series of waking voluntary actions, as totally different from our ideas, recollections, and dreams.

As our belief in the externality of the causes of our sensations means that certain actions of ours will bring the sensations into play, or modify them in a known manner, this belief is readily furnished by experience, and is no more than our experience entitles us to entertain. When we have been repeatedly conscious that a tree becomes larger and larger to the eye in connection with a definite locomotion on our part, called the forward advance; that this movement brings on at last a sensation of touch; that this sensation of touch varies with definite movements of the arms, and so on; the repetition of all this train of experience fixes it on the mind, so that from one thing alone, as from the distant vision of the tree, we can anticipate, or as it is otherwise called, *perceive* all the other consequences. We then know, without going through the steps, that the specified movements will bring about all the sensations above described, and we know nothing else; this knowledge, however, is to us the recognition of external existence, the actual fact that is meant when a material world is spoken of. Belief in external reality is the sure anticipation of certain sensations on the performance of certain movements; everything else said to be implied in it is but a convenient hypothesis for aiding the mind in holding together those multifarious connections that our experience has established in the mind. In order to account for the fact that the conscious movement of elevating the upper eyelid is followed with the sensation of light, to us and to other minds, we suppose a luminous agency always existing even when not affecting us or any other person; we cannot know or verify this supposition—it is a generalization founded upon particular experiences, and serving to sum up those experiences in a convenient form, but no such perennial independent substance can be absolutely proved.

PERCEVAL, SPENCER, RIGHT HON., English minister, was the second son of John, Earl of Egmont; born November 1, 1762; educated at Harrow, and at Trinity College, Cambridge. He was called to the bar, and soon obtained a reputation as a diligent lawyer. A clever pamphlet on the abatement of the impeachment of Warren Hastings, made him known to Pitt. Obtaining a seat in parliament for Northampton, he was soon conspicuous for his extreme horror of popery, and his violent advocacy of what was called by his party the 'Protestant interest.' In the Addington administration, he was made Solicitor-general in 1801, and Attorney-general in 1802. He was afterwards induced to abandon

his profession, and adopt a political career. In the Portland administration of 1807, he was made Chancellor of the Exchequer, and was even then the real head of the government, his influence with George III. being obtained by the depth of his bigotry and his pertinacious opposition to the Catholic claims. On the death of the Duke of Portland in 1809, P. became Premier; uniting to his office of Chancellor of the Exchequer that of First Lord of the Treasury. He was retained in power by the Prince of Wales on his accession to the regency. On the 11th May 1812, about 5 P.M., as P. was entering the lobby of the House of Commons, a man named Bellingham fired a pistol at him, the ball pierced his heart, and he instantly expired. The assassin made no attempt to escape. He was a Liverpool broker, trading with Russia, who, having sustained some losses and injuries, which he had vainly applied to the government to redress, determined to avenge himself by taking the life of the prime minister. P.'s assassination shocked the public mind, and parliament hastened to make an ample provision for his widow and numerous family. His death was, however, rather a private than a public calamity. 'With all my respect for the virtues and excellences of the late minister,' said the Marquis of Wellesley, who had held the office of Foreign Secretary in his administration, 'I still feel it my duty to say that I did not consider him a fit man to lead the councils of this great empire.' He was ready in debate, a placid and not ungraceful speaker, and led the House of Commons with much tact; but he was superficial and intolerant. Sydney Smith, in his *Letters of Peter Plymley*, has conferred a species of immortality upon him by his wit and sarcasm. It was the fashion, when P.'s public policy was attacked, to laud his domestic virtues. 'Peter' said, if he had to choose between public and private virtues, he should prefer that Mr. P. 'owed for the veal of the preceding year, whipped his boys, and saved his country.'

PERCH (*Perca*), a genus of acanthopterous fishes, of the family *Percidae*, to which it gives its name, and which includes many genera and a very great number of species, both of marine and fresh-water fishes. The *Percidae*, or P. family, have the body somewhat oblong and more or less compressed; the scales rather large; the bones of the gill-covers toothed or otherwise armed; the mouth without barbels; the *vomer* toothed, and generally also the palate; there are sometimes two dorsals, sometimes only one. To this family belong not only the true perches, all of which are fresh-water fishes, but the Lates (q. v.) of the Nile, the Basse (q. v.) or Sea P., and their congeners the Pike Perches (q. v.), the

Perch (*Perca fluviatilis*).

Serrani, and many other fishes. The true perches (*Perca*) have two dorsal fins, distinct and separate, the rays of the first spinous and those of the second flexible; the tongue is smooth; and the gill-covers are bony, notched, and sharply serrated. The COMMON P. (*P. fluviatilis*) is an inhabitant of the lakes, ponds, and still rivers of almost all parts of Europe. It is very common in England and Ireland, and is found in many of the waters of the south of Scotland, although in the north it is rare, and is said to exist only where it has been introduced. But it is found in Scandinavia, and even in Lapland. It is of a greenish-brown color, passing into golden-yellow on the under parts, and marked on the back with six or seven indistinct blackish crossbands. Its height is about one-third of its length. It often attains a length of 16 or 18 inches, and a weight of 2 or 3 pounds, but perches have been taken of 8 pounds weight or more. The P. loves still waters, and is easily reared in ponds, but it is not a desirable inmate of ponds intended for other fish, because it is very voracious, and devours their fry.

It is readily caught by almost any kind of bait, and sometimes takes a small artificial fly. It is much esteemed for the table. It lives a long time out of the water if kept moist, and in some countries is thus brought to market, and carried back to the pond if not sold. The female P. deposits her eggs in long strings, united by a viscid matter.—A species of P. (*P. Italica*), found in the south of Europe, differs from the Common P. in its shorter and deeper form, and want of black bands. Several species are natives of the rivers and lakes of North America, and are among the most esteemed of its fresh-water fishes.

PERCH. See ROD.

PERCLO'SE, a railing or other enclosure separating a tomb or chapel from the rest of a church.

PERCLOSE, or DEMI-GARTER, in Heraldry, the lower half of a garter with the buckle.

PERCOLA'TION, a process much used in Pharmacy, and in some other arts, for extracting certain soluble properties of various bodies by filtering a liquid through them. In the new British pharmacopœia, 39 tinctures and 9 extracts are ordered to be prepared by percolation. As the fluid soaks in and passes through the material acted upon, it displaces and carries with it the soluble parts, hence percolation is sometimes called the *Method of Displacement*. The forms of apparatus for percolation are very numerous, but the principle is the same in all—viz., a vessel with a porous bottom, and in the form of a truncated cone inverted, receives the material first, and over it is poured the water or other fluid which is to extract its virtues. One made by an eminent French pharmacien, M. Bejot, is very effective and complete.

A is a long funnel-shaped glass, a glass stop-cock (*b*) in the bottom, which narrows to an inch diameter; this fits into the neck of a large globular vessel B, both being adjusted by grinding. C is a syringe of brass fixed in the glass B as shown, and made airtight by a caoutchouc washer. α^1 , α^2 , α^3 are three diaphragms of

Percolator.

porous felt, pierced by the tube *d*, which allows air bubbles to escape from the bottom without disturbing the fluid. The material to be acted upon, as wood, bark, root, leaves, &c., is first powdered, and is then laid on the top of the uppermost diaphragm, α^1 , so as to half fill the space between it and the glass-cover α^2 ; water, or any other required fluid, is then poured in until it is filled; the stop-cock *b* is opened, and the operator draws the air from the outer vessel by means of the air-pump C, the fluid is thus rapidly drawn through the material, and displaces its soluble parts. α^2 and α^3 arrest the fine solid particles which are carried through the first diaphragm with the liquid, and form sediments which are also acted upon by the liquid which is checked at each division for a time. The fluid, when it reaches the globular glass, however dark colored, is beautifully bright and clear, and the preparations so made are remarkable for their good quality and uniformity of strength. In the year 1864, Dr. Redwood, of the Pharmaceutical Institution of Great Britain, invented a new percolator of great efficacy. It consists of a tinned copper cylinder, with a smaller cylinder of flannel inside, in which the materials are put. The whole is filled with the fluid menstruum, and as that which is in more immediate contact with the solid materials becomes charged with the soluble matter displaced, it gives rise, as its density is increased, to an endosmotic action through the flannel walls of the inner cylinder until the whole is equalized, when it is drawn off by the tap, and fresh fluid added until it comes away colorless. The outer cylinder has a tight cover to prevent loss by evaporation.

PERCUSSION, in Medicine, is the method of eliciting sounds by tapping, or gently striking the surface of the body; its object being to determine by the nature of the sound the comparative density of the subjacent parts. This means of diagnosis was first employed by Avenbrugger in the middle of last century, and it was afterwards adopted by Corvisart in the investigation of heart diseases; but its value was not fully appreciated till Laennec made the diseases of the chest his peculiar study; and since his time, its application and various uses have been considerably extended by the labors of Piorry, Hughes Bennett, and other physicians.

Percussion is chiefly employed in the diagnosis of diseases of the lungs, heart, and abdominal organs. It may be *direct* (or, as some writers term it, *immediate*), or it may be *mediate*. In the former case, the part to be examined is struck with the ends of the three first fingers set close together on the same level, or with a small hammer tipped with India-rubber; while in the latter, which is now almost universally adopted, a flat body is placed upon the chest, or other part to be examined, and is then struck by the fingers or hammer. The flat intervening body is termed a *Pleximeter* (from the Gr. *plexis*, a blow, and *metron*, a measure). The instrument usually sold as a pleximeter is a flat oval piece of ivory, but the left index or middle finger of the physician, with its flat surface fitted accurately to the part to be examined, acts equally well. The force of the stroke on the pleximeter—whether the stroke be made with the fingers or the hammer—must vary according as it is desired to elicit the sound from a superficial or a deep-seated part. The surface to be percussed should be exposed, or, at most, only covered with one layer of clothing; and the blow should fall perpendicularly on the pleximeter. When percussion is made over a considerable cavity filled with air—as the stomach or intestines—a hollow, drum-like, or (as it is usually termed by medical writers) a *tympanitic* sound is produced. When any part of the surface of the chest is struck, below which there is a considerable depth of healthy lung-tissue, consisting of small cells filled with air, a clear sound, less loud and hollow than the tympanitic sound, and termed the *pulmonary percussion note*, depending partly on the vibrations of air in the lung-cells, and partly on the vibrations of the walls of the chest, is evolved.

When the subjacent substance is solid (as the heart, liver, or spleen) or fluid (as when there is effusion in a closed sac), the sound is *dull* in proportion to the density and want of elasticity of the part struck. The first thing that must be acquired in order to make percussion useful in the diagnosis of disease, is an accurate knowledge of the sounds elicited from the different parts in their normal condition. When, for example, the healthy pulmonary percussion note is known, increased resonance of the walls of the chest will indicate a dilatation of the air-cells (or pulmonary Emphysema), while various degrees of dullness will afford evidence of such morbid changes as the effusion of fluid into the pleura (Hydrothorax), or inflammatory solidification of the lung-tissue (the Hepatisation of Pneumonia), or tubercular deposition. The use of percussion in relation to the diagnosis is further shown in the articles PERICARDITIS and PLEURISY.

PERCUSSION CAPS are small copper cylinders, closed at one end, for conveniently holding the detonating powder which is exploded by the act of percussion in percussion-arms. Caps were not used with the earliest percussion-arms, which the Rev. Mr. Forsyth of Belhelvie, Aberdeenshire, patented in 1807; but they became tolerably general between 1820 and 1830, and were adopted for the army by 1840. With the adoption of breech-loading arms, the use of *separate* caps has been discontinued. The cap now forms a part of the cartridge, and at one operation is placed with it in the opened breech of the gun. The manufacture is extremely simple: A sheet of thin copper is stamped into pieces of appropriate shape, which are bent into the form of caps by stamping-apparatus closing round a mandril, the whole being done in one machine by two operations. The caps are then placed in a tray, mouths upward; and the inside of each is touched with a strongly adhesive varnish. Over this is dusted the detonating powder, all the particles which fail to adhere being blown, dusted, or shaken out. A stamper once more is forced into the cap, to fix and compress the powder, and the operation is completed.

For muskets, the caps are charged with equal parts of fulminating mercury and chlorate of potash; for cannon, with a mixture composed of two parts of chlorate of potash, two parts of native sulphuret of antimony, and one of powdered glass; the last ingredient taking no part in the chemical action, and being added merely to increase the friction. For the manner in which a cap is used, see LOCK.

PERCUSSION, CENTER OF. See CENTER OF PERCUSSION.

PERCY. This is the name of a noble Norman family who accompanied the Conqueror to England, and whose head, William de Percy, obtained from his sovereign thirty Knights' Fees in the north of England. The representation of the house devolved (temp. Henry I.) on Agnes, daughter of the 3d baron, who married Josceline of Lovain, brother-in-law of the king, only on condition that he adopted either the surname or the arms of P.; he chose to retain his paternal arms and to assume the P. name. The head of the family at the time was one of the chief barons who extorted Magna Charta from King John; and the 9th feudal lord (temp. Edward I.) showed a similar spirit towards the pope, against whose demands he maintained, with others of the greater barons, the spiritual independence of the English crown. This nobleman's great-grandson was a distinguished military commander under Edward III., and acting as Marshal of England at the cor-

onation of Richard II., was created Earl of Northumberland. He subsequently, however, took up arms against Richard, and placed the crown on the head of Henry of Lancaster, who became Henry IV.

Again dissatisfied with the government, he joined in rebellion with his son Hotspur, for the purpose of transferring the crown to Mortimer, Earl of March. The earl, with the other leaders of this rebellion, fell at Bramham Moor (1407–1408), and his titles became forfeited. These, however, were revived in favor of his grandson, who became Lord High Constable of England, and who was killed at the battle of St. Alban's. This earl's son and successor (the third earl) met a like fate on Towton field, fighting in the van of the Lancastrian army. The 4th earl (who obtained a reversal of his father's attainder) was murdered by the populace in Northumberland, when ordered by the avarice of Henry VII. to enforce a subsidy. The executions of the 6th and 7th earls by Edward VI. and Elizabeth are part of the history of England. The 8th earl was committed to the Tower, on a charge of being concerned in a plot in favor of Mary Queen of Scots, and died a violent death in prison. The 10th earl fought in the civil wars against Charles I., though he took no part with the regicides, and eventually joined in the general effort to bring about the Restoration. The 11th earl left an only child, who succeeded to the ancient barony of P., and marrying Charles, Duke of Somerset, became the mother of Algernon, Duke of Somerset, who was created Earl of Northumberland, with remainder to his son-in-law, Sir Hugh Smithson, of Stanwick, in the county of York, a gentleman of respectable lineage. Sir Hugh, succeeding to the earldom, obtained in 1766 his advancement to the dukedom of Northumberland, which title is now held by Algernon-George Percy, born in 1810, who succeeded to the dukedom in 1867.

PERCY, THOMAS, D.D., an eminent poetical collector, antiquary, and scholar, was born at Bridgenorth, Shropshire, in 1728; was educated at Christchurch, Oxford; and having entered the church, rose to be Bishop of Dromore, in Ireland, 1782. He died in 1811. This amiable and accomplished prelate, the friend of Johnson, Goldsmith, and other distinguished contemporaries, published translations from the Icelandic, a new version of the *Song of Solomon*, the *Northumberland Household Book*, a translation of Mallet's *Northern Antiquities*, &c. His most popular and valuable contribution to our literature was the *Reliques of Ancient English Poetry*, consisting of old heroic ballads and songs, with some modern imitations, in which the editor himself displayed the taste and feeling of a poet. This work appeared in 1765, and P. lived to see four editions of it called for by the public, and to receive the warm commendations of all poetical readers and critics. The *Reliques* were chiefly obtained from an old folio MS. that had fallen into P.'s hands, with the addition of pieces from the Pepys collection at Cambridge, the Ashmole Library at Oxford, the British Museum, and the works of our earlier poets. Certain liberties were taken with some of the ballads—softening touches, repairs, and renovations—for which the editor was severely censured by Ritson and other antiquaries; but the collection was of great value to our literature, recalling the public taste to the rude energy, picturesqueness, and passion of the old chivalrous minstrels and Elizabethan songsters. It captivated the youthful imagination of Walter Scott, and was the inspirer and model of his *Minstrelsy of the Scottish Border*. The memory of P. has been still further perpetuated by a Club Book Association, called the PERCY SOCIETY. See CLUB BOOKS.

PERDIDO, a bay and river of Alabama, U. S. The bay, 20 miles long by 6 to 10 miles wide, opens by a narrow channel into the Gulf of Mexico, 18 miles west of the entrance to Pensacola Bay; the river rises in South-Western Alabama, and bay and river form the boundary between Alabama and Florida.

PE'REGRINE FALCON (*Falco peregrinus*), a species of Falcon (q. v.) found in almost all parts of the world. The female is larger than the male, being about 18 inches in length from the tip of the bill to the tip of the tail, whilst the male is only about 15 inches. The female is the *Falcon* of falconers, and the male the *Tercel*. The plumage of the two sexes is very similar. The back, wings, and tail are bluish-slate or ash-gray, the feathers barred with a darker tint; the crown of the head, back of the neck, and a spot below the eye, nearly black; the front of the neck white, with dark longitudinal lines; the breast, belly, and plumage of the legs, whitish, with dark-brown transverse bars. The wings are very long, reaching almost to the tip of the tail; and the bird is remarkable for its power of flight, being capable of maintaining for a considerable time a rate of more than 100 miles an hour, so that it is often seen far from any of its haunts or breeding-places; whence the name Peregrine, from the Latin *peregrinus*, a wanderer. Its swoop, when rushing on its quarry, is wonderful both for rapidity and force. The P. F. can easily carry through the air a bird or quadruped fully its own weight. Its ordinary prey consists of grouse, woodcocks, rabbits, &c.

The woodcock in vain seeks to escape from it by threading its way among branches of trees and brushwood; the falcon follows, and exhibits at least an equal power of moving with great rapidity in the thicket without getting entangled or stayed.

Sometimes the quarry soars into the air, and seeks safety by trying to keep above the falcon, till both are lost to ordinary sight; but the falcon generally gets uppermost, and 'strikes' it at last. It has thus been known to cut a snipe in two, and at one swoop to strike off the head of a grouse or pigeon. Owing to the quantity of game the P. F. will capture it is ruthlessly trapped or otherwise destroyed, so that this beautiful bird is in danger, like others of its family, of being exterminated. The P. F. is a bird as remarkable for boldness as for power of flight. It has sometimes been seen to pounce on game shot by a sportsman, before it could fall to the ground; and an instance occurred in Yorkshire of a P. F. dashing through the glass of an aviary in a town, and carrying off a bird. It makes its nest on ledges of high rocks, either on the sea-coast or in inland precipices and ravines, and lays from two to four eggs. Numerous localities in Britain have long been noted as breeding-places of the P. F., and some of them are regularly visited for the young birds, which are still trained in certain places, for the sport of falconry. The bird, caught when adult, although more difficult to train, is, however, believed to possess superior qualities. The P. F. is more docile, and becomes more gentle than the Gyr-falcon. The young female of the P. F. has been by mistake described by Pennant and others under the name of the Lanner (q. v.), a species not found in Britain. For fig. of P. F., see FALCONRY.

PEREIRA, JONATHAN, the pharmacologist, was born in the parish of Shoreditch, London, 23d May 1804. After a distinguished career at a classical academy in Finsbury, where he remained for four years, he devoted himself to the study of medicine, and in 1823 was appointed resident medical officer of the General Dispensary in Aldersgate Street, at which institution he became, three years afterwards, lecturer on chemistry. His attention was early attracted to the study in which he has become famous. In 1824, he published a translation of the *London Pharmacopœia*; which was followed by *A Manual for the Use of Students*; *A General Table of Atomic Numbers, with an Introduction to the Atomic Theory*; and other text-books for the use of those who were preparing for medical examinations. He contributed numerous papers to the professional journals on the properties and adulteration of drugs, and laid the foundation of those researches which issued in his great work on *Materia Medica*. In 1832, he resigned the office of lecturer for that of Professor of *Materia Medica* in the New Medical School in Aldersgate Street, and at the same time he succeeded Dr. Gordon as Lecturer on Chemistry at the London Hospital. His *Elements of Materia Medica* (first published in the form of lectures contributed to the *Medical Times and Gazette*) appeared as a separate work in 1839–1840, and at once established his reputation as a pharmacologist. The treatise is remarkable for the extent of its research, the variety of its information, whether scientific, commercial, or practical, and the scrupulous exactness of its statements. In 1841, he procured the licence to practise in London from the College of Physicians; in 1845, he was elected a Fellow of that body; and on the establishment of the London University, he was appointed Examiner in *Materia Medica* and Pharmacy, a post which he filled with admirable efficiency till his death. Among his other contributions to science, the best known are his excellent treatises on *Diet* and on *Polarised Light*, both of which appeared in 1848. His death, which took place on January 20, 1853, was the result of a fall down a flight of steps in the College of Surgeons, and was deeply felt, not only by his professional brethren, but by the numerous scientific bodies, such as the Royal, the Linnæan, and the other societies of which he was a distinguished Fellow.

PEREJASSLAVL, an ancient town of Russia, in the west of the government of Poltava. Pop. (1880) 9500.

PEREKOP, ISTHMUS OF, in South Russia, government of Taurida, 18 miles long, 16 miles broad at its southern, and 5 miles broad at its northern extremity, connects the peninsula of the Crimea with the mainland of European Russia. It is an arid waste of mere sand, or sand combined with clay. There are, however, numerous salt lakes, and salt is extensively made. In the north of the isthmus, and forming the key to the Crimea, is the small town of Perekop. Notwithstanding its advantageous position at the convergence of the numerous roads leading from South Russia into the Crimea, P. is of little commercial importance. Pop. of town (1867), 4993.

PÈRE-LA-CHAISE. See LA-CHAISE.

PEREMPTORY DEFENCES, in Scotch Law, mean defences to an action or suit, which amount to an entire negative of the right of action, as distinguished from a preliminary or temporary defence.

PERENNIAL, in Botany, a term employed in contradistinction to Annual (q. v.) and Biennial (q. v.), to designate plants which subsist for a number of years. Some plants, however, which are annual in cold climates, are perennial in warmer regions. The term perennial is in general applied only to herbaceous plants, and indicates a property only of their roots, the stems of most of them dying at the end of each summer. Perennial herbaceous plants, like shrubs and trees, are capable of producing flowers and fruit time after time, in which they differ from annual and biennial plants, which are fruitful only once. Those plants which are capable of being propagated by cloves, offset bulbs, or tubers, are all perennial. Thus the potato is a perennial plant, although the crop is planted in spring and reaped in autumn, like that of corn, whilst all the corn plants are annuals.—There is great diversity in the duration of life of perennial plants.

PERESLA'V, or PEREIASLA'VLE-ZALIE'SKY, a district town in the middle of Great Russia, in the government of Vladimir, and 70 miles north-west of the city of that name. It was founded in 1052 by George, Prince of Souzdal. It possesses numerous churches and religious institutions; but is principally noteworthy for the factories, which are its main prop, and of which the most important are cotton-mills and print-works for cotton goods. The factories are in an increasingly prosperous condition. The cotton manufactures of P. are exported to the fairs of Nijni-Novgorod and Irbit, and even to China by way of Siberia. Pop. (1867) 7452, employed in the factories and in the productive fishery of Lake Pleshtchieff.

PEREZ, ANTONIO, minister of Philip II. of Spain, was born in Aragon in 1539. His father was Secretary of State under Charles I. and Philip II., and he himself was appointed to this office when only 25 years of age, and acquired the entire confidence of the king. Don Juan D'Austria, having sent his confidant, Juan de Escovedo, to Spain, to solicit aid against the party of Orange; and Escovedo having rendered himself an object of hatred both to the king and to P., the former resolved to put him out of the way by murder, and intrusted P. with the accomplishment of this design, which P., to gratify his own revenge, accomplished accordingly, 31st March 1578. The family of Escovedo denounced P. as the murderer, and all his enemies joined against him. The king at first sought to shield him; but in July 1581 he was arrested, and by torture forced to confess. He succeeded, however, in making his escape to Aragon, where he put himself under protection of its laws. After a long and severe inquiry into his conduct, he was found guilty of many acts of fraud and corruption, and condemned to death in Madrid; but the *Justicia Major*, or highest court of justice in Saragossa, refused to deliver him up. The king applied for aid in May 1591 to the Inquisition, and the Aragonese court delivered him up to its agents, but the people rose in tumult, and liberated him. This happened repeatedly; and at last, in September 1591, Philip II. entered Aragon with an army powerful enough to subdue all opposition, abolished the old constitutional privileges of the country, and caused a number of the principal people to be executed. P., however, made his escape, avoiding the many plots which the king laid for his assassination. He was condemned in Spain as a heretic, but was treated with great kindness in Paris and London. He spent the latter years of his life in Paris, and died there in 1611 in great poverty. P. wrote an account of his misfortunes, which was published at Paris in 1598, under the title of *Relaciones*.

PERFECTIBILITY OF CHRISTIANS, a doctrine held by the Wesleyan Methodists (see METHODISTS), of a *Christian perfection* attainable in this life. It is not a perfection of *justification*, but a perfection of *sanctification*; which John Wesley, in a sermon on Christian Perfection, from the text Heb. vi. 1, 'Let us go on to perfection,' earnestly contents for as attainable in this life by believers, by arguments founded chiefly on the commandments and promises of Scripture concerning sanctification; guarding his doctrine, however, by saying that it is neither an *angelic* nor an *Adamic* perfection, and does not exclude ignorance and error of judgment, with consequent wrong affections, such as 'needless fear or ill-grounded hope, unreasonable love, or unreasonable aversion.' He admits, also, that even in this sense it is a rare attainment, but asserts that 'several persons have enjoyed this blessing, without interruption, for many years, several enjoy it at this day, and not a few have enjoyed it unto their death, as they have declared with their latest breath, calmly witnessing that God had saved them from all sin, till their spirit returned to God.' Concerning all which, the general belief of Protestant Christians is, that these persons were merely more self-complacent and less sensible of their own corruptions than is usual, and that the commands and promises concerning sanctification are all susceptible of an explanation consistent with remaining corruption in believers, and a need of further sanctification, or a continued going on unto perfection whilst this life endures.

That perfection is attainable in this life, is held by the Franciscans, Jesuits, and Molinists in the Church of Rome, but denied by the Dominicans and Jansenists; and its supporters generally lay stress on the distinction between mortal and venial sins.

PERFECTIONISTS, or BIBLE COMMUNISTS, popularly known as FREE-LOVERS, or preachers of Free Love, a small American sect who are equally remarkable for the doctrines which they hold, and for the unfaltering way in which they carry them out in practice. The founder of the sect, John Humphrey Noyes, was born at Brattleborough in Vermont, 11th September 1811, and practised as a lawyer. He then studied theology at Andover and Yale, and became a Congregationalist preacher. He soon adopted new views, and lost his license to preach. The opinions of St. Paul, he held, had been completely misconceived by all the Christian churches; all our ecclesiastical organizations were accordingly blunders. He believed that Christ, on his second advent 'in the spirit,' in 70 A.D., abolished the old Law, and closed the reign of sin which began with Adam; and that he has thenceforth set up His kingdom in the hearts of all willing to accept His reign. For such persons, there was no longer any law or rule of duty; neither the Mosaic code, nor the Sermon on the Mount, nor the ordinances or institutions of civil society, were binding upon them; they were a law unto themselves; they were free to do as they pleased, but—with exceptions which, however, could not invalidate an eternal truth—under the influence of the Divine Spirit which dwelt in them, they could only do that which was right.

His early efforts at establishing a church, made at New Haven, were very discouraging, but he was more successful at Putney. He and his converts, men and women, with their children, put their property into a common stock; they gave up the use of prayer, all religious service, and the observance of the Sabbath; those who were married renounced their marriage ties, and a 'complex marriage' was established between all the males and all the females of the 'Family.' To get rid of the inconveniences which had been found attendant upon the exercise of Christian liberty, Noyes had set up a new principle, viz., sympathy, by which the individual will was to be corrected, which practically imposed upon individuals the duty of deferring to the feelings and opinions of the brethren. He now taught that the Family was wiser than the individual, who *might* stray from the path of grace; that the individual was erring when he differed from the Family; and that the inclinations of individuals must be submitted to the opinion of the Family.

Having dispensed with law, he set up public opinion as a controlling power in its stead; and free criticism of one another by the members of the society became an important feature of his system. Quarrelling, however, broke out among the members; their differences were brought before the law courts; and when the details of the Family system became known, the people of Putney made the place too hot for the Perfectionists. Their establishment was broken up; but a portion of the Putney Family—about fifty men, as many women, and about the same number of children—soon established themselves in a new home, in the sequestered district of Oneida, in the state of New York. Among the things which first drew attention to the Putney Family was controversy which Noyes maintained with the leaders of another society of P. established at Oberlin. The P. were divided upon the question, whether of the two leading features of their system, the profession of holiness and the right of Christian liberty, the one or the other was the more important—some were 'Liberty-men,' others 'Holiness-men.' Noyes took up the controversy on behalf of the latter.

At Oneida Creek, the new 'Family' purchased about 600 acres of forest-land, and proceeded to bring it under cultivation. They have made it one of the most productive estates in the Union; they have also established manufactures of various kinds; and in the course of 30 years, they have become a prosperous, and even a wealthy community of about 250 persons, who live together in a state of great harmony and contentedness. Being already sufficiently numerous, the 'Family' has to reject frequent applications which are made for admission to membership. A similar society has been established at Wallingford. Their neighbors have become accustomed to the P. and their ways, and let them live in peace. On settling at Oneida, the controlling function of criticism was strengthened by being made more systematic; and a regard for the common good, grown strong through habit, has made persons who disavow all laws perfectly submissive to the unwritten laws of public opinion.

In the smallest, as well as in important affairs, the Perfectionist practises submission to the opinion of his brethren: in small matters, he usually gathers it by consultation with some of the older members of the body; important ones are submitted to the 'Family' at their evening meetings. All are busy; and they work as hard for the general interest as men do in the hope of enriching themselves. The men wear no particular garb, but usually

dress like the country people around them; the women have their hair cut short, and parted down the center; abjure stays and crinoline; wear a tunic, falling to the knee, and trousers of the same material; a vest, buttoning high towards the throat; and a straw hat. The 'Family' has breakfast at six o'clock, dinner at twelve, and the evening-meal at six in the afternoon; the more advanced of its members abstain from animal food; they drink no beer, and only a weak home-made wine; and like most of the new American sects, they will have nothing to do with doctors. The women are allowed a good deal of influence.

While all the males and females of the 'Family' are united by a 'complex marriage,' their intercourse—which, in theory, is unfettered by any law—is, in practice, subject to a good deal of regulation. Like everything else, it is subject to the opinion of the society, and certain principles have been so steadily applied to it, that they have gained the force of laws. First, there is the principle of the ascending fellowship. There should be contrast, the P. say, between those who become united in love. That there should be difference of temperament and of complexion has, they say, been well ascertained by physiologists. They hold that there should be a difference in age also, so that the young and passionate may be united to those who have, by experience, gained self-control. In virtue of this principle, the younger women fall to the older men, and the younger men to the older women. A second principle is, that there should be no exclusive attachment between individuals; a third, that persons should not be obliged to receive the attentions of those whom they do not like; and lastly, it is held indispensable that connections should be formed through the agency of a third party—because, without this, the question of their propriety might be withdrawn from criticism, and also, because this affords a lady an easy opportunity of declining.

The human heart, the P. say, is capable of loving any number of times, and any number of persons at the same time, and the more it loves the more it can love. The system of the 'complex marriage' is therefore suitable to, while monogamy imposes a restriction upon, human nature; and they believe that marriage will be spurned by the churches as soon as they get rid of the false notion of the essential sinfulness of love. They are confident that, when they have worked out a few details, still incomplete, their system will be perfect, and that it will, before long, be imitated throughout the length and breadth of America. There are four things, according to Noyes, necessary to the organization of a true family: (1) the reconciliation of its members with God; (2) their salvation from sin; (3) recognition of the brotherhood and equality of man and woman; (4) community of labor and its fruits; and communism can only prosper when the previous conditions exist. The P. hold that for reconciliation to God and salvation from sin nothing is necessary but faith; let a man believe that he is reconciled to God, and his sins are immediately washed away.

PERFORMANCE OF CONTRACTS is one of the modes of satisfying the contract, which may be either by doing some specific thing, or not doing something, or by payment of money. It is a good answer to any action brought by one party against another for breach of contract, that what was contracted for has been already performed.

PERFUMERY, PE'RFUMES (Fr. *parfum*, from Lat. *fumus*, smoke or vapor), delicate fumes or smells. Perfumes are of three distinct classes when derived from plants, and there is a fourth class, which are of animal origin.

CLASS I.—These are the most ancient, and have been in use from the earliest period of which there is record. They consist of the various odoriferous gum-resins, which exude naturally from the trees which yield them; and to increase the produce, the plants are often purposely wounded. The most important are benzoin, olibanum, myrrh, and camphor. No less than 5000 cwt. of these together are annually imported into Britain. Gum-resins form the chief ingredients in 'Incense,' (q. v.), and in Pastilles (q. v.).

CLASS II. are those perfumes which are procured by distillation. As soon as the Greeks and the Romans learned the use of the still, which was an invention imported by them from Egypt, they quickly adapted it to the separation of the odorous principle from the numerous fragrance-bearing plants which are indigenous to Greece and Italy. An essential oil or otto thus procured from orange-flowers bears in commerce to this day the name of Neroli, supposed to be so named after the Emperor Nero. Long before that time, however, fragrant waters were in use in Arabia. Odor-bearing plants contain the fragrant principle in minute glands or sacs; these are found sometimes in the rind of the fruit, as the lemon and orange; in others, it is in the leaves, as sage, mint, and thyme; in wood, as rosewood and sandal-wood; in the bark, as cassia and cinnamon; in seeds, as caraway and nutmeg. These glands or bags of fragrance may be plainly seen in a thin cut stratum of orange-peel; so also in a bay leaf, if it be held up to the sunlight, all the oil cells may be seen like specks. All these fragrant-bearing substances yield by distillation an essential oil peculiar to each; thus is procured oil of patchouly from the leaves

of the patchouly plant, *Pogostemon patchouly*, a native of Burmah; oil of caraway, from the caraway seed; oil of geranium, from the leaves of the *Geranium rosea*; oil of lemon, from lemon-peel; and a hundred of others of more infinite variety.

The old name for these pure odoriferous principles was Quintessence. Latterly, they have been termed Essential Oils; they are now, in modern scientific works, often termed Ottos, from the Turkish word attar, which is applied to the well-known otto or attar of roses. See OIL.

All the various essential oils or ottos are very slightly soluble in water, so that in the process of distillation the water which comes over is always fragrant. Thus, elder water, rose water, orange water, dill water are, as it were, the residue of the distillation for obtaining the several ottos. The process of Distillation (q. v.) is very simple; the fragrant part of the plant is put into the still and covered with water; and when the water is made to boil, the ottos rise along with the steam, are condensed with it in the pipe, and remain floating on the water, from which they are easily separated by decanting. In this way 100 pounds of orange, lemon, or bergamot fruit peel will yield about 10 ounces of the fragrant oil; 100 pounds of cedar wood will give about 15 ounces of oil of cedar; 100 pounds of nutmeg will yield 60 to 70 ounces of oil of nutmeg; 100 pounds of geranium leaves will yield 2 ounces of oil.

Every fragrant substance varies in yield of essential oil. The variety of essential oils is endless; but there are a certain relationship among odors as among tints. The lemon-like odors are the most numerous, such as verberna, lemon, bergamot, orange, citron, citronella; then the almond-like odors, such as heliotrope, vanilla, violet; then spice odors, cloves, cinnamon, cassia. The whole may be classified into twelve well-defined groups. All these ottos are very soluble in alcohol, in fat, butter, and fixed oils. They also mix with soap, snuff, starch, sugar, chalk, and other bodies, to which they impart their fragrance.

The principal consumption of the various fragrant ottos is for scenting soap. Windsor soap, almond soap, rose soap, and a great variety of others, consist of various soaps made of oil and tallow, perfumed while in a melted state with the several named ottos or mixtures of them.

Though snuff is by no means so popular an article in the reign of Victoria as it was in Anne's time, yet the increased population, and the extended exports to colonies, cause a production of scented snuff positively greater now than fifty years ago; and it is especially in demand in the fur countries of Northern Canada. There is a large consumption of fragrant essential oils in the manufacture of toilet powders; under the various names of rose powder, violet powder, &c., a mixture of starch and orris, differently scented, is in general demand for drying the skin of infants after the bath.

Precipitated chalk and powdered cuttle-fish bone, being perfumed with otto of roses, powdered myrrh, and camphor, become 'Dentrifice.' The ottos of peppermint, lavender, rose, and others, are extensively used in scented sweetmeats and lozenges.

More than 200,000 pounds weight of various ottos have been imported into Britain in one year, and valued at over £180,000; to this must be added at least one-third as much again distilled in England. Of the imported articles enumerated, oils of lemon and bergamot, from the Two Sicilies, reached 128,809 pounds, valued at £57,054.

CLASS III.—These are the perfumes proper, such as are used for perfuming handkerchiefs, &c. Contrary to the general belief, nearly all the perfumes derived from flowers are not made by distillation, but by the processes of *enfleurage* and *maceration*. Although this mode of obtaining the odors from flowers has certainly been in practice for two centuries in the valley of the Var, in the south of France, it is only by the publication of a recent work* that the method has been made generally known. The odors of flowers do not, as a general rule, exist in them as a store or in a gland, but are developed as an exhalation. While the flower breathes it yields fragrance, but kill the flower, and fragrance ceases. It has not been ascertained when the discovery was made of condensing, as it were, the breath of the flower during life; what we know now is, that if a living flower be placed near to grease, animal fat, butter, or oil, these bodies absorb the odor given off by the blossom, and in turn themselves become fragrant. If we spread fresh unsalted butter upon the bottom of two desert-plates, and then fill one of the plates with gathered fragrant blossoms of clematis, covering them over with the second greased plate, we shall find that after 24 hours the grease has become fragrant. The blossoms, though separated from the parent stem, do not die for some time, but live and exale odor; which is absorbed by the fat. To remove the odor from the fat, the fat must be scraped off the plates and put into alcohol; the odor then leaves the grease and enters into the spirit, which thus becomes 'scent,' and the grease again becomes odorless.

* *Art of Perfumery*, by Septimus Piesse, Ph. D., 8vo. 50 cuts. Longman. 4th ed., 1880.

The flower farmers of the Var follow precisely this method on a very large scale, with but a little practical variation, with the following flowers—rose, orange, acacia, violet, jasmine, tuberose, and jonquil. The process is termed *enfleurage*. In the valley of the Var, there are acres of jasmine, of tuberose, of violets, and the other flowers named; in due season the air is laden with fragrance, the flower harvest is at hand. Women and children gather the blossoms, which they place in little panniers like fishermen's baskets hung over the shoulders. They are then carried to the laboratory of flowers and weighed. In the laboratory the harvest of flowers has been anticipated. During the previous winter great quantities of grease, lard, and beef-suet have been collected, melted, washed, and clarified. In each laboratory there are several thousand *châssis* (sashes), or framed glasses, upon which the grease to be scented is spread, and upon this grease the blossoms are sprinkled or laid. The *châsse en verre* is, in fact, a frame with a glass in it as near as possible like a window-sash, only that the frame is two inches thicker, so that when one *châsse* is placed on another, there is a space of four inches between every two glasses, thus allowing space for blossoms. The illustration shows the *châsse* with grease and flowers upon it (fig. 1), also a pile of the same as in use. The flower blossoms

Fig. 1.
1, Châssis en Verre; 2, Châssis en Fer.

are changed every day, or every other day, as is convenient in regard to the general work of the laboratory or flowering of the plants. The same grease, however, remains in the *châsse* so long as the particular plant being used yields blossoms. Each time the fresh flowers are put on, the grease is 'worked'—that is, serrated with a knife—so as to offer a fresh surface of grease to absorb odor. The grease being *enfleurée* in this way for three weeks or more—in fact, so long as the plants produce blossoms—is at last scraped off the *châsse*, melted, strained, and poured into tin canisters, and is now fit for exportation. Fat or oil is perfumed with these same flowers by the process of maceration; that is, infusion of the flowers in oil or melted fat. For this end, purified fat is melted in a *bain marie*, or warm bath, and the fresh blossoms are infused in it for several hours. Fresh flowers being procured, the spent blossoms are strained away, and new flowers added repeatedly, so long as they can be procured.

The *bain marie* is used in order to prevent the grease becoming too hot from exposure to the naked fire; so long as the grease is fluid, it is warm enough. Oil does not require to be warmed, but improved results are obtained when it is slightly heated.

Jasmine and tuberose produce best perfumed grease by *enfleurage*, but rose, orange, and acacia, give more satisfactory products by maceration; while violet and jonquil grease is best obtained by the joint processes—*enfleurage* followed by maceration. In the engraving a *châsse en fer* (2, fig. 1) is shown; this is for *enfleurage* of oil. In the place of glass, the space is filled with a wire net; on which is laid a *molleton*, or thick cotton fabric—moleskin, soaked with oil; on this the flowers are laid, just as with solid grease. In due time—that is, after repeated changing the flowers—the oil becomes fragrant, and it is then pressed out of the moleskin cloth. Oil of jasmine, tuberose, &c., are prepared in this way. In order now to obtain the perfume of these flowers in the form used for scenting handkerchiefs, we have only to infuse the

scented fat or oil, made by any of the above methods, in strong alcohol.

In extracting the odor from solid fat it has to be chopped up fine as suet is chopped, put into the spirit, and left to infuse for about a month. In the case of scented oil it has to be repeatedly

Fig. 2.
1, Bain Marie; 2, Section of Bain Marie.

agitated with the spirit. The result is, that the spirit extracts all the odor, becoming itself 'perfume,' while the grease again becomes odorless; thus is procured the essence of jasmine, essence of orange flowers, essence of violets, and others already named, rose, tuberose, acacia, and jonquil.

It is remarkable that these flowers yield perfumes which, either separate or mixed in various proportions, are the types of nearly all flower odors; thus, when jasmine and orange flowers are blended, the scent produced is like sweet pea; when jasmine and tuberose are mixed, the perfume is that of the hyacinth. Violet and tuberose resemble lily of the valley. All the various bouquets and nose-gays, such as 'frangipanni,' 'white roses,' 'sweet daphne,' are made upon this principle.

The commercial importance of this branch of perfumes may be indicated by the quantity of flowers annually grown in the district of the Var. Flower Harvest: orange blossoms, 1,475,000 lbs.; roses, 530,000 lbs.; jasmine, 100,000 lbs.; violets, 75,000 lbs.; acacia, 45,000 lbs.; geranium, 30,000 lbs.; tuberose, 24,000 lbs.; jonquil, 5000 lbs.

CLASS IV. Perfumes of animal origin.—The principal are Musk (q. v.), Ambergris (q. v.), Civet (q. v.), and Castor (q. v.). The aroma of musk is the most universally admired of all perfumes; it freely imparts odor to every body with which it is in contact. Its power to impart odor is such, that polished steel will become fragrant of it if the metal be shut in a box where there is musk, contact not being necessary.

In perfumery manufacture, musk is mixed with other odorous bodies to give permanence to a scent. The usual statement as to the length of time that musk continues to give out odor has been called in question. If fine musk be spread in thin layers upon any surface, and fully exposed to a changing current of air, all fragrance, it is said, will be gone in from six to twelve months.

Civet is exceedingly potent as an odor, and when pure, and smelled at in the bulk of an ounce or so, is utterly insupportable from its nauseousness; in this respect it exceeds musk. When, however, civet is diluted so as to offer but minute quantities to the olfactories, then its perfume is generally admitted; this is so with gas-tar; but the fragrant principle is the same as that breathed by the beautiful narcissus. Castor is in our day almost obsolete as a perfume.

The average importation of musk per annum for a period of five years was 9388 ounces, value £10,688; export 1578 ounces, value £2143; leaving for home-consumption every year 7810 ounces, value £8545. Average importation per annum for a similar period; otto of roses 1117 ounces, value £13,561; vanilla 3525 pounds, value £12,568; ambergris 225 ounces, value £225; civet 355 ounces, value £300; orris root 420 hundredweight.

The works on perfumes are very few; that of Madame Celnart, in the Librairie Roret, is most worthy of notice among the French; a translation of it has been made by Mr. C. Morfit of Philadelphia. In England, *The British Perfumer*, by C. Lilly (1822), was the only work of the kind published in England prior to the *Art of Perfumery* by S. Plesse (1855). See also Rimmel's *Book of Perfumes* (1875).

PE'RGAMUS, or PERGAMUM, anciently a city of Mysia in Asia Minor, on the navigable river Caicus, at the distance of 120

stadia from the sea. According to tradition, the place was of Greek origin, but its early history is quite insignificant. It first acquired prominence when Lysimachus, one of Alexander's generals, chose it as a stronghold in which to keep his treasures. Under Phileteus it became the capital of a state, 283 B.C. His successor, Eumenes I., maintained its independence against the Seleucidae, although the title of king was first assumed by Attalus I., who reigned from 241 to 197 B.C. He intimately allied himself with the Romans against Philip of Macedon, and this alliance subsisted throughout succeeding reigns, in which the kingdom increased in extent and importance, till at last Attalus III., surnamed Philometor, who died in 133 B.C., left it with all his treasures to the Romans, who successfully maintained the right thus acquired, and under whom the city continued to flourish. It was the focus of all the great military and commercial routes of Asia Minor, and Pliny describes it as *longe clarissimum Asia Pergamum*. The Attali collected in P. a library only inferior to that of Alexandria. It was also the seat of a famous grammar-school, and it gave its name to Parchment (q. v.). P. sank under the Byzantine emperors, but the place still exists under the name *Bergamah*, and is noted for the splendor and magnificence of its ruins, which embrace temples, palaces, aqueducts, gymnasia, amphitheatres, and city walls.

PERGOLESE, GIOVANNI BATTISTA, an eminent musician of the Neapolitan school. Evidence regarding the date and place of his birth is conflicting; probably the correct account is that of the Marchese di Villarosa, his latest biographer, who states that he was born at Jesi, near Ancona, on the 3d of January 1710. In 1717 he was admitted into the Conservatorio dei Poveri di Gesù Cristo at Naples, where he studied the violin under Domenico di Mattei, and musical composition under Gaetano Greco and Durante. Under the conviction that melody and taste were sacrificed to learning by most of the masters of his time, he abandoned the style of Scuriatti and Greco for that of Vinci and Hasse. His first great work was the oratorio of *San Guglielmo d'Aquitania*, composed in 1731. In that and the following year appeared his operas of *La Serrà Padrona*, *Il Prigionier Superbo*, and *Lo Frate Innamorato*; in 1734, *Adriano in Siria*; in 1735, *Il Flaminio* and *L'Olimpiade*. In 1734, he received the appointment of *maestro di cappella* of the Church of Loreto. In consequence of delicate health, he removed to Pozzuoli, where he composed the cantata of *Orfeo*, and his pathetic *Stabat Mater*. He died there of consumption in 1736. Besides the above-mentioned works, P. composed a number of pieces for the church, which were better appreciated during his lifetime than his secular compositions, also a violin concerto, and thirty trios for violin, violoncello, and harpsichord. His works are all characterized by sweetness and freedom of style.

PERI (Fairy), according to the mythical lore of the East, a being begotten by fallen spirits, which spends its life in all imaginable delights, is immortal, but is for ever excluded from the joys of Paradise. It takes an intermediate place between angels and demons, and is either male or female. So far from there being only female Peris, as is supposed by some, and these the wives of the Deys, the Peris live, on the contrary, in constant warfare with these Deys. Otherwise, they are of the most innocuous character to mankind, and exactly as the fairies, with whom our own popular mythology has made us familiar, are, when female, of surpassing beauty. One of the finest compliments to be paid to a Persian lady is to speak of her as Perizadeh (born of a Peri; Greek, Parisatis). They belong to the great family of genii, or jin: a belief in whom is enjoined in the Koran, and for whose conversion, as well as for that of man, Mohammed was sent (cf. Koran, chaps. lv., lxxii., and lxxiv.).

PERIAGUA, a large canoe composed of the trunks of two trees, hollowed and united into one fabric; whereas an ordinary canoe is formed of the body of one tree only. Periaguas are used in the Pacific, and were formerly employed among the West India Islands, whence the frequent allusion to them in *Robinson Crusoe*.

PERIANTH (Gr. *peri*, around, *anthos*, a flower), in Botany, the floral envelope (see FLOWER) of those plants in which the calyx and corolla are not easily distinguished. The term is convenient, as it can be applied indifferently to the calyx and corolla; thus, when there is either a calyx or corolla existing, but not both, the perianth is said to be *single*; when both are present, *double*. Both are really present in many endogenous plants, to which the use of the term perianth is confined by some botanists; the single floral envelope of exogenous plants being regarded as a calyx, and the corolla supposed to be wanting. The perianth is *regular* in some plants, *irregular* in others. It often displays great beauty, as in tulips, crocuses, lilies, &c.

PERICARDITIS, or Inflammation of the Pericardium (q. v.), is a disease of frequent occurrence; the result of a very large number of post-mortem examinations being to show that about

1 in 23 of all who die at an adult age exhibits traces of recent or old attacks of this disorder.

For reasons which will be obvious when we come to speak of the physical signs of this disease, we shall commence with a notice of the anatomical changes which take place in the inflamed membrane. Very soon after symptoms of pericarditis begin to show themselves there is an abnormal dryness of the serous membrane, which is speedily followed by an increased secretion of fluid.

The secreted fluid is sometimes almost entirely fibrinous, in which case it coagulates, and gives rise to adhesions between the heart and the pericardium; or it may consist almost entirely of serum, which remains liquid; or it may be, and it most frequently is a mixture of the two. When there is a large amount of liquid effusion (as, for instance, a third of a pint or more) which is not re-absorbed, death usually takes place in the course of a few days, in consequence of the interference of the fluid with the heart's actions; but when there is not much liquid effusion, or when the liquid part is absorbed, the pericardium becomes more or less adherent, and apparent recovery usually takes place.

In the cases that prove fatal when fibrinous fluid has been effused, but has not coagulated to such an extent as to cause complete adhesion of the heart to the pericardium, the partially coagulated fibrin (or lymph, as the older authors styled it) is seen to be of a yellowish-white color, and to occur in a rugged, shaggy, or cellular form. Laennec compared the surface on which the lymph is deposited to that which would be produced by suddenly separating two flat pieces of wood between which a thin layer of butter had been compressed. Dr. Watson regards the appearance more like the rough side of pieces of uncooked tripe than anything else; while others have compared it to lace-work, cut sponge, a honey-comb, a congeries of earthworms, &c. When the patient dies at a more advanced stage of the disease—viz., soon after the whole of the membrane has become adherent—incipient blood-vessels, in the form of red points and branching lines, are seen, indicating that organization is commencing in the deposit, which if death had not ensued would have been finally converted into cellular or areolar tissue, and have occasioned the complete obliteration of the pericardial cavity.

The symptoms of pericarditis are pain in the situation of the heart, increased by a full inspiration, by pressure upon or between the ribs in the cardiac region, and especially by pressure upwards against the diaphragm by thrusting the fingers beneath the cartilages of the false ribs; palpitations; a dry cough and hurried respiration; discomfort or pain on lying on the left side; restlessness; great anxiety of countenance; and sometimes delirium. The pulse usually beats from 110 to 120 in a minute, and is sometimes intermittent; and febrile symptoms are always present. These symptoms are seldom collectively present in any individual case, and until the time of Louis the diagnosis of this disease was uncertain and obscure. The physical signs, dependent on the anatomical changes which have been described, are, however, generally so distinct that by their aid the disease can be readily detected. They are three in number. 1. In consequence of irritation propagated to the muscular tissue of the heart at the commencement of the inflammation of its investing membrane, the ventricles contract with increased force, rendering the sounds of the heart louder and its impulse stronger than in health, or than in the more advanced stages of the disease. 2. When much fluid is effused into the pericardium, dullness on percussion is always observable to a greater degree than in health. This sign, which is very characteristic, is seldom perceived till the disease has continued for two or three days. In relation to this increased dullness, we must premise that in the healthy condition of the heart and lungs there is an irregular roundish space with a diameter of somewhat less than two inches, extending from the sternum (or breast-bone) between the level of the fourth and fifth ribs towards the left nipple, in which a portion of the surface of the heart is not overlapped by the lungs, but lies in contact with the walls of the chest. This space should normally be dull on percussion. In pericarditis the extent of the dullness beyond the normal limit indicates the amount of effusion. In extreme cases the dullness may extend over a space whose diameter is seven inches or more. Simultaneous with the increased dullness, there is a diminution of the heart's sounds in consequence of the intervening fluid, and the impulse is often scarcely perceptible.

3. The rubbing of the inflamed and roughened surfaces upon each other gives rise to a sound which is commonly called the *friction sound*, but which has received various names. Thus Dr. Watson calls it a *to and fro* sound, and observes regarding its variations that, 'like all the other morbid sounds heard within the chest, it is capable of much variety in tone and degree. Sometimes it very closely resembles the noise made by a saw in cutting through a board; sometimes it is more like that occasioned by the action of a file or of a rasp; but its essential character is that of *alternate rubbing*; it is a *to and fro* sound.' This sound is heard early in the disease, before the surfaces of the pericardium are separated

by the effusion of fluid; and it is due either to the dryness of the membrane, or to its roughness from the deposition of lymph. When the contiguous surfaces are either separated by fluid, or become adherent, the sound disappears; but when it has been lost from the first of these causes, it reappears after the fluid has been so far absorbed as to permit the surfaces again to come in contact. But here, again, its duration is brief, for the surfaces soon become adherent and cease to rub upon each other.

Pericarditis is a disease which occasionally runs a very rapid course and terminates fatally in forty-eight hours or less. In ordinary cases, however, which terminate in apparent recovery, the disease generally begins to yield in a week or ten days, and excepting that adhesion remains, the cure appears to be complete in three weeks or less. But although these patients *apparently* recover, the pericardial adhesion commonly occasions other structural changes of the heart sooner or later to develop themselves; and in those cases that the physician has the opportunity of subsequently watching, it is observed that fatal disease of the heart, primarily due to the pericarditis, almost always supervenes. In slight cases it is probable that a true cure, without adhesion, may take place.

Pericarditis frequently arises from exposure to cold when the body is warm and perspiring. It is no uncommon result of a contaminated state of the blood, such as occurs in the exanthematous diseases, especially scarlatina, and in Bright's disease of the kidney; but beyond all comparison, it is of most frequent occurrence in association with acute Rheumatism (q. v.), of which it forms by far the most dangerous complication.

At the commencement of the disease, blood should be freely taken (if the patient is tolerably robust) from the region of the heart either by cupping or repeated leeching; and at the same time every attempt must be made to get the system under the influence of mercury to the extent of rendering the gums tender and of affecting the breath. Not only should calomel in small doses, and combined with opium with the view of preventing purging, be frequently given, but mercurial ointment should be rubbed into the arm-pits and inner sides of the thighs, and the mouth should be kept slightly sore for some time. After three or four days, if there should be much fluid effusion, a large blister should be applied over the heart; and if the patient is not already under the influence of mercury, the raw surface may be dressed with mercurial ointment. Perfect rest both of body and mind is of essential importance, and all possible causes of excitement should be excluded. The diet should be mild and chiefly farinaceous, and little or no animal food should be allowed till the beginning of convalescence. Cooling drinks are agreeable to the patient, and may be taken freely with advantage throughout the disease.

PERICARDIUM, THE, is a conical membranous sac, containing the heart and the commencement of the great vessels, to the extent of about two inches from their origin. It is placed with its apex upwards behind the sternum, and to its left side, in the interval between the pleuræ—the serous sacs in which the lungs are enclosed; while its base is attached to the diaphragm. It is a fibro-serous membrane, consisting of an external fibrous and an internal serous layer. The fibrous layer is a strong, dense, fibrous membrane; the serous layer invests the heart, and is then reflected on the inner surface of the fibrous layer. Like all serous membranes, it is a closed sac; its inner surface is smooth and glistening, and secretes a thin fluid which serves to facilitate the natural movements of the heart. It is inflammation of this serous sac which constitutes the disease known as pericarditis.

PE'RICARP. See **FRUIT**.

PE'RICLES (Gr. **PERIKLES**), the most accomplished statesman of ancient Greece, was born of distinguished parentage in the early part of the 5th c. B.C. His father was that Xanthippus who won the victory over the Persians at Mycale, 479 B.C., and his mother, Agariste, was the niece of the great Athenian reformer Cleisthenes. P. received an elaborate education; but of all his teachers, the one whom he most revered, and from whose instructions he derived most benefit, was the philosopher Anaxagoras (q. v.). P. was conspicuous all through his career for the singular dignity of his manners, the 'Olympian' thunder of his eloquence, his sagacity, probity, and profound Athenian patriotism. When he entered on public life, Aristides had only recently died, Themistocles was an exile, and Cimon was fighting the battles of his country abroad. Although the family to which he belonged was good, it did not rank among the first in point of either wealth or influence, yet so transcendent were the abilities of P. that he rapidly rose to the highest power in the state as the leader of the dominant democracy. The sincerity of his attachment to the 'popular' party has been questioned, but without the shadow of evidence. At any rate, the measures which either personally or through his adherents he brought forward and caused to be passed, were always in favor of extending the privileges of the poorer class of the citizens. P. seems to have grasped very

clearly, and to have held as firmly, the modern 'radical' idea, that as the state is supported by the taxation of the body of the citizens, it must govern with a view to general and not to *caste* interests. In 461 B.C., P. through the agency of his follower, Ephialtes, struck a great blow at the influence of the oligarchy, by causing the decree to be passed which deprived the Areopagus of its most important political powers. Shortly after, the democracy obtained another triumph in the ostracism of Cimon. During the next few years the political course pursued by P. is not very clearly discernible, but in general his attitude was hostile to the desire for foreign conquest or territorial aggrandizement, so prevalent among his ambitious fellow-citizens.

In 454 B.C., or shortly after, he magnanimously proposed the measure (which was carried) for the recall of Cimon, and about the same time commenced negotiations with the other Hellenic states with the view of forming a grand Hellenic confederation, the design of which was to put an end to the mutually destructive wars of kindred people—to make of Greece one mighty nation, fit to front the outlying world. The idea was not less sagacious than noble. Had it been accomplished, the semi-barbarous Macedonians would have menaced the civilized Greeks in vain, and even Rome at a later period might perhaps have found the Adriatic, and not the Euphrates, the limits of her empire. But the Spartan aristocrats were utterly incapable of morally appreciating such exalted patriotism, or of understanding the political necessity for it, and by their secret intrigues brought the well-planned scheme to naught. Athens and Sparta were already, and indeed had for some time been, in that mood towards each other which rendered the future Peloponnesian war inevitable. They are always found on opposite sides. When the Spartans, in 448 B.C., restored to the Delphians the guardianship of the temple and treasures of Delphi, of which they had been deprived by the Phocians, the Athenians immediately after marched an army thither, and reinstated the latter. Three years later, an insurrection broke out in the territories tributary to Athens, Megara, Eubœa, &c., and the Spartans again appeared in the field as the allies of the insurgents. The position of Athens was critical. P. wisely declined to fight against all his enemies at once. A bribe of ten talents sent the Spartans home, and the insurgents were then rapidly and thoroughly crushed.

Cimon was now dead, and was succeeded in the leadership of the aristocratical party by Thucydides, son of Milesias, who in 444 B.C. made a strong effort to overthrow the supremacy of P. by attacking him in the popular assembly for squandering the public money on buildings, and in festivals and amusements. Thucydides made an effective speech; but P. immediately rose and offered to execute the buildings at his own expense, if the citizens would allow him to put his own name upon them instead of theirs. The sarcasm was successful, and P. was empowered to do as he pleased in the matter. But P. did not mean to be simply sarcastic; he wished to point out to the Athenians in a delicate way the spirit and aim of his policy, which was to make Athens, as a city worthy of being the head and crown of Hellas. His victory in the assembly was followed by the ostracism of Thucydides; and during the rest of his career 'there was,' says the historian Thucydides, 'in name a democracy, but in reality a government in the hands of the first man.' The same author, however, informs us that he never did anything unworthy of his high position; that he did not flatter the people, or oppress his adversaries; and that with all his unlimited command of the public purse, he was personally incorruptible. Soon after this the Samian war broke out, in which P. acquired high renown as a naval commander. This war originated in a quarrel between the Milesians and Samians, in which Athens was led to take a part with the former. The Samians, after an obstinate struggle, were beaten, and a peace was concluded in 440 B.C. The position in which Athens then stood towards many of the Greek states was peculiar. Since the time of the Persian invasion she had been the leader of the confederacy formed to resist the attacks of the powerful enemy, and the guardian of the confederate treasury kept in the isle of Delos. P. got the treasury removed to Athens, and, commuting the contingents of the allies for money—Athens, of course, herself undertaking to protect the confederacy—enormously increased the contributions to the 'patriotic fund.'

The grand charge against P. is, that he applied the money thus obtained to other purposes than those for which it was designed; that, in short, he adorned and enriched Athens with the spoils of the allied states. But the objection is more plausible than solid, for, in point of fact, Athens kept up in admirable discipline a great fleet and a fine army, and P. made the Greek name more respected in his time than it had ever been before. It may be that his conduct is open to criticism in some respects, but a broad and just view of the motives which impelled him to act as he did, and a fair consideration of the political exigencies of the time will, in the main, justify his procedure. It is unnecessary to give a detailed account of all that he did to make his native city the most glorious in the ancient world. Greek architecture and sculpture,

under his patronage, reached perfection. To P., Athens owed the Parthenon, the Propylæa, the Odeum, and numberless other public and sacred edifices; he also liberally encouraged music and the drama; and, during his rule, industry and commerce were in so flourishing a condition, that prosperity was universal in Attica.

At length, in 431 B.C., the long-foreseen and inevitable 'Peloponnesian war' broke out between Athens and Sparta. With the circumstances that led to it we have not here to do, but as it terminated most disastrously for Athens, it is but right to say that P. is not to blame for the result. Had the policy which he recommended been pursued, one can hardly doubt that Athens, with her immense resources, would have been the victor, and not the vanquished, in the struggle. P. himself died in the autumn of 429 B.C., after a lingering sickness. His character has been sufficiently delineated in the outline of his life which we have given. His connection with the brilliant Aspasia (q. v.) is noticed elsewhere.

PERIER, CASIMIR, a celebrated French statesman, was born at Grenoble, in the department of Isere, France, 21st October 1777. His father had enriched himself by mercantile and industrial pursuits, into which he initiated his two elder sons; but Casimir was still studying at the college of the Oratory at Lyon when the revolution broke out. He immediately went to Paris, and there associated himself with his father and elder brother Antoine-Scipion in their endeavors to found a banking company. It is sufficient to notice here that the banking company was firmly established, and became the Bank of France. Casimir was drafted into the army in 1798, and served in an engineering corps till 1801, when he returned to Paris, and resumed the position of coadjutor to his brother. The house of P. prospered greatly under the empire; the peace which followed the events of 1815 aided the development of their plans, and gave a wider scope to their enterprises; and the public regarded with special favor men such as these two brothers, who devoted their abilities and fortunes to foster the growth of public, as well as their own, prosperity. In 1817, P. published three tracts, in which he condemned the financial policy of the ministry. These papers made a lively impression on the public, and led to the return of the author to the Chamber of Deputies by the electors of Paris. P., in his political principles, was essentially a Constitutionalist, equally far removed from absolutism on the one hand, and extreme democracy on the other. The elections of 1824, conducted under government influence, resulted in the ousting of the greater portion of the Constitutionals. P., however, and a few others of the chiefs of the party retained their seats; but their opposition to the ministerial measures, though constant and unwearied, was quite ineffective; it, however, raised them greatly in public opinion, and secured their re-election in 1827. In this year, P. had the honor of being elected as representative by both the departments of the Seine and the Aube. He defended the loyal and sagacious administration of M. de Martignac, whose representations to the king, Charles X., seemed to have the effect of reconciling the royal party to government in conformity with the charter; but the subsequent rule of the Prince de Polignac reduced this hopeful state of affairs to its former critical condition.

The revolution (of July 1830), which P., from his experience of that of 1789, had made every endeavor to prevent, now followed, and it only remained for him to render it as bloodless as possible. In this he was successful, through his great influence with the people of Paris. On August 3, he was elected President of the Chamber of Deputies, but resigned this office on the 11th of the same month to become a member of the ministry. When Laffitte became President of the Council (November 2), P., fearing that the tendencies of the ministry were too revolutionary, resigned office, and resumed the presidency of the Chamber of Deputies. On 13th March 1831, he succeeded to Laffitte as minister, and gave his whole attention to the repression of revolution, the maintenance of order at home and of peace abroad, originating the political system known as the *justemilieu* (q. v.). His foreign policy was very successful; he greatly contributed to the maintenance of Belgian independence, the suppression of the Miguelite insurrection in Portugal, the counterbalancing of Austrian influence in Italy, and, in general, to the spread and progress of constitutional liberty both at home and abroad; but the rapid growth of extreme liberalism in France, partly owing to previous encouragement unwittingly afforded by himself, was a source of great annoyance to him. On the outbreak of cholera in Paris, March 1832, P. made the most extraordinary exertions for the enforcement of the necessary sanitary measures; but he was attacked by the disease, and his system being already exhausted by over-exertion, he died, 16th May 1832. No public man in France was ever so generally and sincerely lamented, and a monument to his memory was erected by public subscription in the cemetery of Père-la-Chaise.

PERIGEE (Gr. *peri*, near; *ge*, earth), that point in the moon's orbit which is nearest to the earth. The opposite point is the Apogee (q. v.). See MOON.

PÉRIGUEUX, a town of France, capital of the department of Dordogne, and situated on the right bank of the Isle, 68 miles east-north-east of Bordeaux. It consists of the ancient city of P. Proper—which is gloomy in aspect, and has narrow streets, but large and solidly-built houses—and the *Puy St. Front*, which, until the year 1240, was a separate and a rival town. In the old town, there are many curious remains of Gothic architecture. The old ramparts have been demolished, and replaced by beautiful and spacious boulevards. The cathedral of St. Front is a majestic edifice, restored at the end of the 15th century. Quarries of building-stone are worked in the vicinity, and many hands are employed in cutting and polishing marble. Paper, woollen cloths, cutlery, and hosiery are manufactured. The celebrated *Pâtés de Périgueux*, made of partridges and truffles, are largely made and exported. Pop. (1876) 23,290.

P., a town of the highest antiquity, is the *Vesunna* mentioned by Cæsar. In ancient times, it was a city of much importance. It stood at the junction of five Roman roads, and contained a number of splendid edifices. Close to the modern town are still to be seen the remains of a vast amphitheater, oval in form, and larger in its dimensions than the ancient amphitheater of Nîmes. There are also remains of ancient aqueducts, baths, and temples. The *Tour de Vésone* is the most remarkable fragment of Roman architecture. It is still 67 feet high, and appears to have been much higher; is 200 feet in circumference, and has walls 6 feet thick. It has neither doors nor windows. Its purpose is not known.

PERIHE'LION (Gr. *peri*, and *helios*, the sun), that point in its orbit at which a planet is nearest the sun: The point of the orbit opposite to it is called the Aphelion (q. v.). The position of the perihelion, i. e., its longitude east or west of the equinox, is one of the seven elements of a planet's orbit.

PERI'M, a small island belonging to Great Britain, situated in the strait of Bab-el-Mandeb, at the entrance to the Red Sea. Lat. 12° 40' 30" N., long. 48° 23' E. P. is level, and is slightly elevated above the sea, and is 3½ miles long; is 1½ m. from the Arabian, and 9 m. from the African coast. Pop. (1871) 211. On both sides of this island the navigation is easy; the Little Strait, between the island and Arabia, is the passage most generally taken by vessels. The island is bare, destitute of fresh water, and ill-furnished with provisions, which are brought for the most part from Aden. P. owes its importance wholly to its commanding position at the entrance of the Red Sea. On its south-west side is an excellent harbor, capable of accommodating 40 men-of-war, within 100 yards from the shore. There is a walled light-house on the island. Fortifications were erected on the island in 1857, but, with the temporary arsenal, &c., were subsequently removed again. It was captured by Sir David Baird, and then occupied by the English in 1799, and held by them as a check upon the designs of the French, who were then in Egypt. It was abandoned in 1801, but was reoccupied by Great Britain in 1857, with a view to the protection of her Indian possessions, which were thought to be exposed to some chance of danger by the opening of the Suez Canal (q. v.).

PERI'METER (Gr. *peri*, around, *metron*, a measure) and PERI'PHERY (Gr. *phero*, I carry) are terms denoting the boundary, or the length of the boundary, of any closed plane figure; though the term 'perimeter' is generally confined to those figures which are bounded by straight lines.

PERINÆUM. The part of the human body which forms the floor of the true pelvis is by anatomists divided into two portions. Of these, the anterior one, situated in front of the anus, is called the *true perinæum*, or urethral portion of the perinæum; the posterior portion, which contains the anus or termination of the rectum, is called the ischio-rectal region, or anal portion of the perinæum. The anterior portion, or true perinæum, is triangular in form, the apex being in front; the sides, about three inches in length, are formed by the rami of the pubes and ischium; and the base by an imaginary line joining the tuberosities of the ischium, and passing about half an inch in front of the anus. Through this space the urethra passes through a layer of strong fascia—the deep perinæal fascia—to communicate with the bladder, and in this space the opening is made in the operation of lithotomy.

PERIOD, a term used in Chronology in the same sense as Cycle (q. v.), to denote an interval of time after which the astronomical phenomena to which it refers recur in the same order. It is also employed to signify a cycle of cycles. Various periods have been invented by astronomers, but we can only notice a few of the most important.

The Chaldeans invented the *Chaldaic Period* or *Period of Eclipses*, from observing that, after a certain number of revolutions of the moon round the earth, her eclipses recurred in the same order and of the same magnitude. This period consists of 233 lunations, or 6798·28 days, and corresponds almost exactly to a complete revolution of the moon's node. The Egyptians made

use of the *Dog-star*, *Siriacal*, or *Sothric Period*, as it is variously called, to compare their civil year of 365 days with the true or Julian year of 365 $\frac{1}{4}$ days. The period consequently consisted of 1460 Julian years, corresponding to 1461 Egyptian years, after the lapse of which the dates in both reckonings coincided. By comparing the solar and lunar years, Meton, an Athenian, invented (432 B.C.) a lunar period of 6940 days, called from him the *Metonic Cycle* (q. v.), also the *Lunar Cycle*. About a century afterwards, the cycle of Meton was discovered to be an insufficient approximation to the truth, and as he had made the solar year too long by about $\frac{1}{4}$ th of a day, at the end of 4 Metonic cycles the solar reckoning was in advance of the lunar by about 1 day 6 hours.

To remedy this, a new period, called the *Calippic Period*, was invented by Calippus, and consisted of 4 Metonic cycles less by 1 day, or 27,759 days. But as this period still gave a difference of 6 hours between the solar and lunar reckonings, it was improved by Hipparchus, who invented the *Hipparchic Period* of 4 Calippic periods less by 1 day, or 111,035 days, or about 304 Julian years, which is an exceedingly close approximation, being only 64 minutes too long, when measured by the tropical year; and too short but by an almost inappreciable quantity, when measured by the *Synodic Month* (see MONTH). The period of the *Heliacal* or *Solar Cycle*, after which the same day of the month falls upon the same day of the week, consists of 28 Julian years. If the year had regularly consisted of 365 days, that is, one day more than an exact number of weeks, it is evident that, at the end of seven years, the days of the month and week would again correspond; but the introduction of an intercalary day into every fourth year causes this coincidence to recur at irregular periods of 6, 11, 6, and 5 years successively. However, by choosing a period such as will preserve the leap-years in the same relative position to the other years, and at the same time consist of an exact number of weeks (both of which objects are effected by using the number 28, which is the least common multiple of 4 and 7), we insure the regular recurrence of the coincidence between the days of the week and of the month. The solar cycle is supposed to have been invented about the time of the Council of Nice (325 A.D.), but it is arranged so that the first year of the first cycle corresponds to 9 B.C. In calculating the position of any year in the solar cycle, care must be taken to allow for the omission of the intercalary day at the beginning of each century, and its insertion in the first year of every fourth century. See LEAP-YEAR. The year 1880 is the 13th of the solar cycle. The *Julian Period* is a cycle of cycles, and consists of 7980 ($= 28 \times 19 \times 15$) years, after the lapse of which the solar cycle, lunar cycle, and the Indiction (q. v.) commence together. The period of its commencement has been arranged so that it will expire at the same time as the other three periods from which it has been derived. The year 4713 B.C. is taken as the first year of the first period, consequently, 1 A.D. was the 4714th of it, and the year 1881 was the 6594th.

PERIODICAL, a publication which appears continuously at regular intervals, and whose contents may be devoted to criticism, politics, religion, literature, science, arts, amusement, or general and miscellaneous subjects. Those periodicals which consist of a collection of critical essays are called *Reviews*.

The earliest periodical in Great Britain seems to have been the *Philosophical Transactions of the Royal Society*, which first appeared in 1665, and contained notices of books as well as original papers. Periodicals professing to notice the books that were being published appeared soon after from time to time under the name of *All the Works of the Learned*; and in 1692 appeared the *Gentlemen's Journal*, or *Monthly Miscellany*, properly speaking, the first English magazine. The *Gentleman's Magazine* was founded in 1731 by Cave the printer, a periodical which secured a fortune for its proprietor, and, after surviving all its competitors, still exists, though lately somewhat assimilated in form to the new class of magazines. The periodical literature of Scotland was long represented by the *Scots Magazine*, founded in 1739. The first English periodical that attempted anything like criticism was the *Monthly Review*, begun in 1749. It was followed in 1756 by the *Critical Review*, founded by Smollett; and these two were long the leading periodicals of their class, though their criticism was but meager and unsatisfactory, according to our present notions. Another critical journal, called the *Anti-Jacobin*, was established in 1798. In 1802 a new era in criticism was inaugurated by the establishment in Scotland of the *Edinburgh Review* (q. v.); which was followed in London by the *Quarterly Review*, of about equal merit and opposite politics, supported by Sir Walter Scott, Southey, S. T. Coleridge, Heber, and at a later period by Hartley Coleridge, Lord Mahon, and Gladstone. Another very important periodical, *Blackwood's Magazine*, sprung up in Edinburgh in 1817, under the auspices of John Wilson and Lockhart, as much above the literary mark of former magazines, as the *Edinburgh and Quarterly* were above the mark of preceding reviews, strongly devoted to the interests of conservatism, and in its early years, somewhat violent in its politics.

The review, in the course of time, became the favorite medium for all parties to disseminate their views on political, literary, or theological subjects. Of various reviews after the model of the *Edinburgh and Quarterly*, and published, like them, four times in the year, some, as the *North British Review* and *National Review*, after having had a flourishing existence for some time, succumbed to the demand for cheaper periodicals, appearing at more frequent intervals. Among existing reviews appearing quarterly may be mentioned the *Edinburgh and Quarterly*, which are still among our foremost periodicals; the *Westminster Review*, established 1824, characterized by freedom in handling philosophical and theological topics, and containing essays by J. S. Mill, Carlyle, Grote, John Sterling, and Lord Houghton; and the *Dublin Review*, Roman Catholic, founded in 1836. Many of the newer reviews appear monthly. Of these, the *Contemporary Review* and *Nineteenth Century* are both very ably conducted; as is also the *Fortnightly Review* (at first published twice a month), considered the organ of the very advanced liberal party. There are also weekly reviews, which unite with the review more or less of the character of a newspaper; of these, the most influential are the *Athenæum*, established in 1828; the *Spectator*, in 1828, the *Saturday Review*, in 1856; and the *Academy*, in 1869. Some daily papers, like the *Pall Mall Gazette*, provide a weekly issue, resembling these. Other reviews are *Nature* (1869), weekly; *Knowledge* (1881), weekly; the *Popular Science Review* (quarterly); and *Mind* (1876), quarterly. The articles in the older reviews are generally anonymous; in the newer, it has become to a large extent the practice for the authors to exhibit their names.

The greater part of magazines or periodicals of a more miscellaneous character appear monthly, and their system of management is somewhat similar to that of reviews; but the articles are generally shorter, the subjects more varied, consisting often of tales and novels, which appear there as serials, continued from number to number. Some of the most popular novels of the present day have first been published in magazines. *Blackwood* was the precursor of half-crown monthly magazines, the most important being *Fraser's Magazine*, established in 1830 (discontinued in 1882); but in 1859 and 1860, several new magazines, *Macmillan's Magazine*, the *Cornhill*, *Temple Bar*, *London Society*, and the *St. James's Magazine*, were started at the cheaper price of a shilling. Then followed the era of sixpenny magazines, such as *Good Words*, *Quiver* (1860), *Longman's Magazine* (1882), the *Cornhill* (new and cheap series), and the *English Illustrated Magazine* (1888—an imitation of the beautifully illustrated American magazines). In Great Britain, there are now many weekly periodicals, chiefly of an instructive and amusing kind, price from a penny to three-pence each. This class of publications received an impetus and proper direction by the issue of *Chambers's Journal* and the *Penny Magazine* of the 'Society for the Diffusion of Useful Knowledge' in 1832. These weekly sheets are often issued accumulatively in monthly parts under a cover. The rate of payment for writing in the higher class reviews is usually £10, 10s. per sheet of 16 demy 8vo pages; in the weekly periodicals, half a guinea to a guinea per column is ordinarily paid, but in some instances the price paid is very much greater; such particularly is the case as regards novels.

The quarterly reviews, and the magazines in course of weekly or monthly publication, in 1881, numbered 1097, and of these above 300 were denominational or religious. Of this number only about 12 are, strictly speaking, reviews.

France possessed as far back as 1665 a critical review called the *Journal des Savants*, which, after a lengthened interruption, began again in 1816, and holds a respectable position as a scientific journal. A number of literary and scientific journals sprung up in last century, as the *Nouveau Journal des Savants*, *Journal Littéraire*, *Journal Encyclopédique*, &c. Among the best was the *Magasin Encyclopédique*, begun in 1795, and from 1819 to 1835, combined with the *Revue Encyclopédique*. One of the most noted critical journals in Europe is published in Paris, the *Revue des Deux Mondes*, which began in 1829, and has, since 1831, appeared fortnightly. In it and the other French periodicals of the same kind, the review form is not so completely preserved as with us: a proportion of tales, poetry, &c., is admitted, and the names of the contributors are required to be attached to their articles. The *Revue des Deux Mondes* has had many shortlived imitators, more or less identified with different political parties. The principal French reviews of more recent date are the *Revue Contemporaine*, *Athenæum Français*, and *Revue d'Europe*.

In Germany, reviews have taken even a deeper root than in England. The *Göttinger Gelehrte Anzeigen*, which is the oldest publication of the kind, still preserves a high character. German criticism can, however, hardly be said to have begun before the time of Lessing, who, in conjunction with Nicolai of Berlin, established, in 1757, the *Bibliothek der schönen Wissenschaften*, and afterwards various other journals, characterized by an independence of thought unknown before. The *Allgemeine Literaturzeitung*, founded at Jena in 1785, was a periodical of a still higher character, having for contributors the most eminent liter-

any men of the period. When transferred from Jena to Halle, another journal, called the *Jenaische Allgemeine Literaturzeitung*, sprung up at the former place, under the auspices of the celebrated literary circle at Weimar, of whom Goethe was the center. These two periodicals existed till 1848. Of modern German reviews, the *Deutsche Rundschau* and the *Literarisches Centralblatt* are specimens of two different types. The *Deutsches Museum*, the *Gartenlaube* (the most widely read of German periodicals, with a circulation of nearly 400,000), and *Im Neuen Reich*, are rather magazines than reviews.

Italy possessed a critical journal, *Giornale dei Letterati*, as far back as 1710, conducted by Apostolo Zeno, which continued for 23 years. A new journal of the same name, founded at Pisa in 1771, attained considerable repute. From 1826 to 1880, the *Biblioteca Italiana* and *Antologia di Firenze*, were reviews of considerable ability. The scientific periodicals of Italy are generally creditable. More than 80 periodicals are now published in Rome alone, the number having rapidly increased since the events of 1870.

The United States of America possess a large variety of periodicals, quarterly and monthly, and in a less degree weekly, issuing chiefly from the presses of Boston, New York, and Philadelphia. The most noted critical journal is the *North American Review*, established in 1815; and the best known magazines are *The Atlantic Monthly*, *Harper's Monthly*, and *Scribner's Monthly* (known since 1881 as *The Century*)—all of which, but especially the two latter, are very largely read and sold in the United Kingdom. Many of the less reputable of the American periodicals systematically incorporate articles, without permission or payment, from the periodicals of Great Britain.

Latterly, as is well known, many of the periodicals, both of Europe and America, have acquired an interest by the introduction of wood-engravings. See WOOD-ENGRAVING. See Mitchell's *Newspaper Press Directory*, and Poole's *Index* (new ed., 1882).

PERIODICITY (in Physiology and Pathology). The tendency manifested by various phenomena occurring in living animals to recur, after equal, or nearly equal intervals of time, is so marked, that Bichat, the great French anatomist and physiologist, described it under the title of the *Loi d'Intermittence*. The alternation of sleeping and waking, the phenomena of menstruation, and the punctual return of hunger, are some of the most obvious instances of periodicity that can be suggested as occurring in the healthy subject; while less obvious examples are afforded by the apparently regular variations that have been observed in the excretion of carbonic acid from the lungs, and in the number of the pulsations of the heart at different periods of the 24 hours. As is well known by experience, periodicity may be usefully cultivated and fixed in daily habits. This is well exemplified in the case of sleep, but in a more special degree by the daily relieving of the bowels at a particular hour, a habit in which it is important that all young persons should be carefully instructed with a view to health and convenience.

In certain forms of disease, the law of periodicity or intermission is very distinctly seen. The regular periodic recurrence of the paroxysms of intermittent fever (or ague), is universally known, although the cause of the periodicity has hitherto baffled all inquiry. Amongst those who have tried to solve this question may be mentioned Willis, Reil, Bailly, Roche, Cullen (who ascribes periodicity to 'a diurnal revolution affecting the animal economy'), and more recently, Laycock, who refers it to the diurnal atmospheric changes in relation to pressure, electricity, &c.

Ague often gives rise to periodic diseases which present no close analogy to that disease. Thus it—or, at all events, malaria—is a frequent cause of tic douloureux, recurring at regular intervals; cases are recorded in which periodical vomiting, occurring weekly, or, in one case, at an interval of ten days, seemed to be due to it; and Mr. Moore, surgeon to the Middlesex Hospital, not long ago published the case of a woman who experienced a periodical inflammatory swelling of the right knee, as a sequence of that disorder. Epilepsy is a disease in which the intervals (especially in women) tend to a regular period. Sir Henry Holland (*Medical Notes and Reflections*, 2d ed., page 341) records a case in which 'six attacks occurred, with intervals of sixteen or eighteen minutes between; so exactly recurring, as noted by the watch, that it was impossible to suppose it a mere casualty;' and another, 'where a spasmodic seizure, more of tetanic than epileptic character, occurred twice a day for many weeks successively, and almost exactly at the same hours each day.' For many other examples of periodic or intermittent morbid action, the reader is referred to a memoir by Henle, 'On the Course and Periodicity of Disease,' in his *Pathologische Untersuchungen*; and to Sir Henry Holland's essay (to which we have already referred) in his *Medical Notes and Reflections*. The most important practical fact in relation to this class of diseases is, that they almost invariably yield to the action of certain medicines, especially bark and arsenic.

Exercising a beneficial or mischievous influence, as the case may be, the habit of periodicity is to be sedulously shunned in every instance likely to prove morally or physically prejudicial. No more marked example of the injudicious cultivation of periodicity could be given, than in the evil practice of periodical blood-letting, which once prevailed all over Europe, and was only abandoned in recent times as not only useless, but in all respects injurious.

PERIE'CI (Gr. *Perioikoi*, literally, 'dwellers round about,' i. e., round about some particular locality or city) was the name given, in ancient Greece, to the original Achæan inhabitants of Laconia by their Dorian conquerors. The P. were not slaves, like the Helots (q. v.); they were merely a vassal population, personally free, cultivating their own ground, and carrying on most of the home and foreign trade of Laconia, but possessing no political rights, incapable of intermarrying with the Dorians of Sparta, or of holding important state-offices, and subjected to a land-tax in token of their dependent condition. They have been—as regards their political position—compared to the Saxons of England after the Norman conquest, and seldom has a historical parallel been so sound. The P. must have been very numerous, for they occupied at one time upwards of 100 cities, several of which were on the coast, whence the whole seaboard of Laconia bore the name of the *Perioikis*, and they produced capital sailors, which doubtless accounts for the anomalous fact of P. being occasionally invested with the command of the Spartan fleet. They also formed a part of the Spartan army. At the battle of Plataea (479 B.C.), there were 10,000 P. present. These dependent Achæans were not, however, all on a dead level of vassalage; they lived in regularly organized communities, where the social distinctions of rank, refinement, and wealth were as marked as elsewhere. Xenophon speaks of 'accomplished and well-born gentlemen' (*kaloì k'agathoi*) among the P. serving as volunteers in the Spartan army; and such artists and men of culture as Lacedæmon produced, in all probability belonged to this class. P. also existed in the other Dorian communities of the Peloponnesus.

PERIO'STEUM (Gr. *peri*, around, and *osteon*, bone), a tough fibrous membrane which surrounds the various bones. It is highly vascular, and is the means by which the outer layers of the shafts and the greater part of the spongy portions of the bones are supplied with blood. 'From the internal surface of the periosteum also is produced a layer of soft blastema (or plastic fluid in which cells are developed), by means of which, additions are made to the exterior of the growing bones. The process of ossification going on in the inner part of this blastema, contributes to the thickness of the bone, while a fresh supply is continually being added to the exterior of the blastema, through the medium of the vessels of the periosteum.'—Humphry *On the Human Skeleton*, page 19. In young bones, this membrane is thick, and in consequence of the intervening blastema, is very easily detached from the bone; but in the bones of the adult it is less thick and vascular, while its connection with the bone becomes closer, in consequence of the blastema being less; while in aged persons it is very thin, its vessels are scanty, and there is no blastema. Numerous experiments show that the formation of bone is essentially due to the action of this membrane; and that, by transplanting detached portions of periosteum into muscular or other tissues, bony tissue is generated in those parts. In most cases in which this membrane has become detached in consequence of a wound or of disease, the exposed bone (except in the instance of the skull, which derives most of its nutrient matter from the dura mater) perishes; but this is not invariably the case. Amongst its other offices, it serves, by isolating the bone from the surrounding tissues, to prevent the spread of disease from them to it. The shin-bone or tibia is thus indebted to the periosteum for its ordinary immunity, in cases of ulcer in that region. In those parts in which the bone is not so completely isolated from the surrounding tissues, as at the ends of the bones of the fingers and toes, inflammation of the soft parts not unfrequently extends to the bony structure.

PERIOSTI'TIS, or INFLAMMATION OF THE PERIOSTEUM, generally occurs on the surface of thinly-covered bones, such as the tibia, clavicles, and cranial bones. Its chief causes are (1) a *sphilitic taint*, in which oval swellings, called *Nodes* (q. v.), are produced; (2) *rheumatism*; and (3) *scrofula*. In the two latter cases, there is a periosteal swelling around the whole circumference or surface of the bone. The affection, especially when due to the first or second of the above causes, is usually accompanied with considerable nocturnal pain. If the disease occurs in an acute form, it must be treated with leeches, fomentations, and the other ordinary antiphlogistic (or lowering) remedies. When it becomes chronic, the treatment must be mainly directed to the cause which has originated it. In almost all cases, the nocturnal pains are best relieved by somewhat large doses

(five to ten grains) of iodide of potassium, taken three times a day on an empty stomach.

PERIPATE'TIC PHILOSOPHY, a designation of the philosophy of Aristotle (q. v.) and of his followers. It is of doubtful origin, being supposed to have been derived either from his custom of occasionally walking about (*peripatein*) during the delivery of his lectures, or from the place in which they were delivered being a shaded walk.

PERIPATUS. See **ARTICULATA**.

PERIPNEUMONIA, an inflammation of the membrane which invests the lungs, accompanied with general disturbance of the whole system; remarkably prevalent among horses in South Africa, in a zone from 20° to 27° S. lat. It is very fatal; and to its prevalence and virulence, Dr. Livingstone is disposed to ascribe the fact that horses, although so abundant in the more northern parts of Africa, were unknown in the south till introduced by Europeans; this invisible barrier being more insurmountable than mountain ranges, deserts, or rivers. The season during which peripneumonia prevails is from December to April. Zebras, antelopes and oxen are liable to its attacks, but no kind of quadruped suffers so much from it as the horse. The flesh of animals which die of peripneumonia is unwholesome, and produces a malignant carbuncle.

PERIPTERAL (Gr. *peri*, and *pteron*, a wing), a term applied to temples or like buildings having columns all round the cella.

PERISSODACTYLA. See **ARTIODACTYLA**.

PERISTALTIC MOTION. The term *peristaltic* (Gr. *clasp*ing and *compress*ing) and *vermicular* (or worm-like) are applied to the peculiar motion or action of the muscular coat of the intestines, by which the substances contained within it are regularly moved onward.

This action of the intestines is readily seen on opening an animal (a dog, cat, or rabbit, for example) immediately after it has been killed; and in these circumstances, it is perhaps exaggerated, from the stimulating action of the cold air; and it may be shown in an abnormally active state, although not altered in character, by subjecting the exposed intestines to the influence of the electromagnetic machine.

It appears, from the observations made by Brinton, Todd and Bowman, and others on recently killed animals, that the peristaltic motion commences at the pyloric third of the stomach (see **DIGESTION, ORGANS OF**), whence successive waves of contraction and relaxation are propagated downwards throughout the whole length of the intestinal canal. 'In examining a portion of intestine at the moment of its contraction, we perceive a dilatation above it as well as below it; the latter being produced by the protrusion into it of the contents of the now contracted portion of intestine; the former by the relaxation of a previously contracted portion. The rapid succession of these contractions and relaxations gives to the movements of the intestines the appearance of the writhings of a worm, whence they are distinguished by the appellation *vermicular*.'—Todd and Bowman's *Physical Anatomy of Man*, vol. ii. p. 236. These movements can occasionally be observed during life in the human subject, indirectly, in cases of extreme attenuation of the abdominal walls, and directly in wounds of the abdomen, and during certain surgical operations. There are differences of opinion as to the causes of peristaltic action; thus, Todd and Bowman assert that 'the intestinal movements are partly due to the influence of the stimulus of distention upon the muscular tissue, and partly to the reflex action of the ganglia of the intestinal portion of the sympathetic, stimulated by the contact of the intestinal contents with the mucous membrane,' while Carpenter maintains that 'the intestinal tube from the stomach to the rectum is not dependent upon the nervous centers either for its contractility or for its power of exercising it, but is enabled to propel its contents by its own inherent powers.'

Numerous observations tend to show that this motion has a nearly definite velocity in each individual. Most commonly the act of defecation takes place with perfect regularity every 24 or (more rarely) every 12 hours, the quantity discharged being almost constant, if the mode of living does not vary. Heberden (*Commentarii*, p. 14) mentions a person who regularly had a motion once a month, and (by way of contrast) another who had twelve motions every day during thirty years, and then seven every day for seven years, and rather grew fat than otherwise. Pouteau (*Œuvres Posthumes*, tome i. p. 27) records the case of a young lady who had no stool for upwards of eight years, although during the last year she ate abundantly of fruit, and drank coffee, milk, and tea, and broth with yolk of eggs; but she had copious greasy sweats. Such a case as this is possible, but far from probable.

That the influence of *expectant attention* on the muscular movements of the intestine (and especially of its lower portion) is very great, is shown in various ways. It is, for the most part, thus that *habit* operates in producing a readiness for defecation

at one special hour in the day, and that bread-pills and other equally inert substances act on the bowels, if the patient believes them to be purgatives. Dr. Carpenter, in his remarks on 'the influence of expectant attention on muscular movements,' in the chapter of his *Human Physiology* treating 'Of Muscular Movements,' mentions two very striking cases of the kind which have fallen within his own knowledge.

PERISTYLE, a colonnade around the interior of a courtyard or other building.

PERITONEUM (Gr. *periteinein*, to extend around), a serous membrane, and like all membranes of this class, a shut sac, which, however, in the female, is not completely closed, as the Fallopian tubes communicate with it by their free extremities. The peritoneum more or less completely invests all the viscera lying in the abdominal and pelvic cavities, and is then reflected upon the walls of the abdomen, so that there is a visceral and a parietal layer. Numerous folds are formed by the visceral layer as it passes from one organ to another. They serve to hold the parts in position, and at the same time enclose vessels and nerves. Some of these folds are termed *Ligaments*, from their serving to support the organs. Thus, we have ligaments of the liver, spleen, bladder, and uterus formed by peritoneal folds. Others are termed *Mesenteries* (from the Gr. *meson*, the middle, and *enteron*, the intestine), and connect the intestines with the vertebral column. They are the Mesentery proper (q. v.), which has been already described, the ascending, transverse, and descending

The Reflections of the Peritoneum :

Dm, the diaphragm; S, the stomach; C, the transverse colon; D, the duodenum; P, the pancreas; I, the small intestine; R, the rectum; B, the urinary bladder; 1, the anterior, and 2, the posterior layer of peritoneum; 4, the lesser omentum; 5 and 6, the greater omentum; 7, the transverse mesocolon; 10, the mesentery encircling the small intestine; 11, the recto-vesical fold; 12, the anterior layer traced upwards upon the internal surface of the abdominal wall to the point (1) with which the examination commenced.—From Wilson's *Anatomist's Vade-mecum*.

meso-colon, and the meso-rectum. (The mesentery and transverse meso-colon are shown in the figure.) Lastly, there are folds called *Omenta*, which proceed from one viscus to another. They are three in number—viz., the *Lesser* or *Gastro-hepatic Omentum*, which extends from the under-surface of the liver to the lesser curvature of the stomach (No. 4 in fig.); the *Gastro-splenic Omentum*; and the *Great* (or *Gastro-colic*) *Omentum* (Nos. 5 and 6 in fig.), which consists of four layers of peritoneum, the two which descend from the stomach, and the same two returning upon themselves, and ascending as high as the transverse colon, where they separate, and enclose that organ. These separate layers may be easily seen in the young subject, but in the adult they are more or less blended. The great omentum always contains some adipose tissue, which, in persons inclined to corpulency, often accumulates to an enormous extent. Its use appears to be (1) to protect the intestines from cold by covering them anteriorly as with an apron, and (2) to facilitate their movement upon each other during their vermicular action.

Like all serous membranes, the peritoneum readily takes on inflammation from various exciting causes. This inflammation is termed **Peritonitis** (q. v.).

PERITONITIS, or **INFLAMMATION OF THE PERITONEUM**, may be either an acute or a chronic disease.

Acute Peritonitis generally presents well-marked symptoms. It sometimes commences with a chill, but severe pain in the abdomen is usually the first symptom. The pain is at first sometimes confined to particular spots (usually in the lower part of the abdomen), but it soon extends over the whole abdominal region.

It is increased, on pressure, to such an extent that the patient cannot even bear the weight of the bedclothes; and to avoid, as far as possible, internal pressure upon the peritoneum, he lies perfectly still, on his back, with the legs drawn up, and breathes by means of the ribs, in consequence of the pain occasioned by the descent of the diaphragm in inspiration. The breathing is naturally shallow in these cases, and less air being admitted at each movement of respiration, the number of those movements is increased. There are perhaps forty or even sixty respirations executed in a minute, instead of eighteen or twenty. The pulse is usually very frequent, often 120 or more in the minute, and small and tense though occasionally strong and full at the commencement of the attack. After the disease has continued for a certain time, the belly becomes tense and swollen; the enlargement being caused at first by flatus, and afterwards also by the effusion of fluid, as may be ascertained by percussion and auscultation.

The progress of the disease is in general rapid. In fatal cases, death usually takes place within a week, and often sooner. The symptoms indicating that the disease is advancing towards a fatal termination are great distention of the abdomen, a very frequent and feeble pulse, a pinched and extremely anxious appearance of the face, and cold sweats.

Peritonitis may arise from any of the ordinary causes of inflammation, such as sudden change of temperature (especially the combined effects of cold and wet on the surface of the body), excessive use of stimulating fluids, the suppression of long-standing discharges, translation of gout and rheumatism, &c. It is frequently the result of local violence, and of wounds penetrating the peritoneal sac, including various surgical operations. Besides the above causes, there are two which give rise to special varieties of peritonitis, viz., contagion or infection, which often prevails epidemically, and produces great mortality amongst women after childbirth, giving rise to puerperal peritonitis, one of the most perilous accompaniments of the awful disorder known as Puerperal Fever (q. v.); and perforation of the stomach, bowels, gall bladder, urinary bladder, &c., by which their contents are allowed to escape into the peritoneal cavity, where they excite the most violent inflammation. Peritonitis from perforation is characterized by the suddenness of the attack; intense pain, incapable of mitigation by medicine, all at once arising in some part of the abdomen, the whole of which soon becomes tender in every part. This form of the disease is generally fatal, death usually ensuing within two days, and sometimes within a few hours. Perforation of the small intestine, in consequence of ulceration of its glands, is of not uncommon occurrence in continued (typhoid) fever, and sometimes occurs in phthisis. That apparently useless structure, the vermiform appendage of the cæcum, is a comparatively frequent seat of perforation. Sometimes it is the stomach which is perforated, and in these cases the patients are usually unmarried women (especially domestic servants), who had previously appeared in good health, or at most had complained of slight dyspepsia.

The only disease with which peritonitis is likely to be confounded by the well-educated practitioner is a peculiar form of hysteria; but the age and sex of the patient, the presence of hysteria in other forms, and the general history of the patient and of her symptoms, will almost always lead to a correct diagnosis of the disease.

The treatment, in an ordinary case of peritonitis (not arising from mechanical injury, or perforation from disease, or occurring in connection with puerperal fever), consists, if the patient is moderately robust, in bleeding from the arm, till a decided impression has been made on the circulation; after which the abdomen should be covered with twenty or thirty leeches, and the bleeding from their bites should be encouraged by fomenting the belly with flannels rung out of hot water, or, if the patient can bear its weight, by the application of a light poultice. The system must, at the same time, be got as speedily as possible under the influence of mercury, by the means described in the treatment of Pericarditis (q. v.). Opium may be given freely, not merely to guard against the purgative action of the calomel, but with the view of securing sleep to the patient, and quiet to the inflamed membrane. The patient must be kept on low diet, unless indications of sinking appear. In peritonitis from perforation, the only remedy is opium, which must be given in large and repeated doses, so as to keep the bowels perfectly at rest, in order to promote the formation of adhesion, by which alone the patient can be possibly saved. For the same reason, perfect rest must also be insisted on, and even drinks forbidden, thirst being allayed by the application of ice to the tongue.

Chronic Peritonitis occurs in two forms, which differ in their origin and degree of fatality, but are very similar in their symptoms. In the first, the inflammation is of the ordinary character, and although the disease sometimes originates spontaneously, it is more frequently the sequel of an imperfectly cured acute attack; in the second, it depends upon granules (supposed by Louis and most writers to be tubercles) lying in countless numbers in the serous membrane, and serving as a constant source of

irritation. The second form is confined almost, if not entirely, to persons of a scrofulous constitution.

The symptoms of chronic peritonitis are more obscure than those of the acute form. There is abdominal pain, often slight, and not always constant, which is increased by pressure, or sometimes is felt only when pressure is made. The patient complains of a sensation of fulness and tension of the belly, although its size is not visibly increased; of a loss of appetite; and of nausea and vomiting; and the bowels are usually more or less out of order. After a time, the abdomen enlarges, and becomes tympanitic, or more or less filled with fluid; and death gradually ensues from debility and emaciation, unless the fatal issue is accelerated by an acute inflammatory attack.

It is not always easy to determine, during life, whether the disease belongs to the first or second form. When its origin cannot be traced to a preceding acute attack, to local abdominal injury, or to chronic affections of the abdominal viscera, there is strong reason to believe it to be of the granular, or, as it is commonly called, the tubercular form, especially if the general constitution and the hereditary tendencies of the patient point in the same direction.

Little can be done in the way of treatment, especially in the tubercular form, further than mitigating the most distressing symptoms, and possibly retarding the final issue. The frequent application of a few leeches to the abdomen, followed by warm poultices, occasional blisters, attention to the bowels, which, if costive, should be acted upon by gentle laxatives, and a mild, nourishing, but unstimulating diet, are more likely to be of service than remedies of a more energetic nature.

PERIWINKLE (*Littorina*), a genus of gasteropodous molluscs of the order *Pectinibranchiata* and family *Littorinidae*, having a proboscis-shaped head, a foot of moderate size, a single gill, and a rudimentary siphonal canal; the shell turbinate, thick, with few whorls, and no nacreous lining; the operculum of few whorls. A very well-known species is the COMMON P. (*L. littorea*), a snail-like mollusc most abundant on rocky parts of the British coasts, living in the lowest zone of sea-weeds between tide-marks, and feeding on fuci, &c. It is oviparous. No mollusc is more generally collected and used for food. Children are generally employed in collecting it. It is boiled in the shell, and so sold, often on the streets, and chiefly to the poorer classes, although few molluscs are more pleasant. It is calculated that 1900 tons, value £15,000, are annually consumed in London alone. It is called *Wilk*, *Wulke*, or *Whulke* in Scotland, but is quite different from the *Whelk* (q. v.) of the English, notwithstanding the sameness of name. Other species, *L. neritoides* and *L. rudis*, are common on all rocky parts of the British coasts, but are less esteemed. *L. rudis* is viviparous, and the shells of the young within the mantle of the parent often make it gritty and unpleasant to eat.

PERIWINKLE (*Vinca*), a genus of plants of the natural order *Apocynaceæ*, having a 5-cleft calyx, and a salver-shaped corolla bearded at the throat, with five obliquely truncated segments. The leaves are opposite and evergreen; the flowers grow singly or in pairs from the axils of the leaves. The LESSER P. (*V. minor*), a native of many parts of Europe, and of the southern parts of Britain, growing in woods and thickets, is a half-shrubby plant with trailing stems, rooting at their extremities, ovate-lanceolate leaves, and pale-blue—sometimes white or reddish-purple—salver-shaped flowers. The GREATER P. (*V. major*), which has much larger flowers and ovato-cordate ciliated leaves, is a native of the south of Europe, and is found in a few places in the south of England. Both of these species are very commonly planted in shrubberies and gardens, rapidly cover unsightly objects with pleasing green foliage, and produce their beautiful flowers at almost all seasons of the year, even in winter when the weather is mild. The HERBACEOUS P. (*V. herbacea*), a Hungarian species, is remarkable for the abundance of its flowers. The YELLOW P. (*V. lutea*) is a native of the southern parts of North America. The ROSE-COLORED P. (*V. rosea*), a native of Madagascar, is a favorite greenhouse plant.—The name P. was formerly *Periwinké*. Chaucer speaks of the 'fresh perwinké rich of hue.' It is probably from the French *pervenche*, and that from the Latin *vinca*.

PERJURY is the crime committed by one who, when giving evidence on oath as a witness in a court of justice, or before some constituted authority of the same kind, gives evidence which he knows to be false. But in order to make the giving of the false evidence liable to criminal punishment, it must have been not only false to the knowledge of the witness, but the matter must have been material to the issue raised. If the falsehood occurred as to some trifling or immaterial fact, no crime is committed. Moreover, it is necessary, in proving the crime, that at least two persons should be able to testify to the falsehood of the matter, so that there might be a majority of oaths on the matter—there being then two oaths to one. But this rule is satisfied though both witnesses do not testify to one point. The perjury must

also have taken place before some court or tribunal which had power to administer the oath. See OATH. Though in some courts affirmations are allowed instead of oaths, yet the punishment for false affirmation is made precisely the same as for false swearing. The punishment for perjury was, before the Conquest, sometimes death or cutting out the tongue; but latterly, it was confined to fine and imprisonment, and at present the latter is the only punishment, with the addition of hard labor. The crime of Subornation of Perjury—i. e., the persuading or procuring a person to give false evidence, is also punishable as a distinct offence.

PERKIN WARBECK. See HENRY VII.

PE'RLEBERG, a town of Prussia, province of Brandenburg, on the Stepnitz, with woollen and machine manufactures, tanneries, &c. Pop. 7900.

PERM, the most eastern government of European Russia, is bounded on the E. by Siberia, and on the N., W., and S. by the governments of Vologda, Viatka, and Orenburg respectively. Area, 128,210 square miles—more than twice the area of England and Wales. Pop. (1879) 2,439,134. It is divided by the Ural Mountains into two unequal parts, of which the smaller portion is on the eastern or Siberian side of the mountains, although, for administrative purposes, it is reckoned as a part of European Russia. About three-fourths of the government are occupied by the Ural range, which in some places reaches the height of 4000 feet; but which slope so gradually towards the plain, that the traveler reaches their summit before he is aware that he has made any unusual ascent. About two-thirds of the entire surface, comprising all the northern districts, are covered with forests, one-tenth of the area is in meadows, and about the same extent is under cultivation. The more important rivers belong to the systems of the Volga and the Obi. The Kama, together with the Tshousovaia and other affluents from the Ural Mountains, flow south-west, join the Volga, and thus form an important means of communication between the mining districts of P. and Europe. The Tura, the Sosva, and the Losva communicate with the Obi; and access is opened up to the White Sea and the Arctic Ocean by the rivers Dwina and Petchora. The climate is healthy, though somewhat rigorous. At the end of July, the nights are cold; in the middle of September, falls the first snow. In November, when the whole face of nature is covered with snow, the transport of goods by sledges is busily carried on everywhere. In January, the cold is so great that quicksilver sometimes freezes. At the end of March, the snow begins to melt, and before the middle of May, although the cold is still great, the country is clothed in the green of early spring. The chief products are gold, copper, magnetic iron ore, rock-crystal, jasper, agate, topaz, porphyry, malachite, porcelain clay, salt (obtained from salt springs), coal, alabaster, marble, &c., and diamonds in small quantities. The inhabitants are chiefly Russians, but there are also numbers of Tartars, Bashkirs, and Finns.

The agricultural produce of the government, consisting chiefly of corn, vegetables, flax, and hemp, is more than sufficient for local consumption, and is exported so some extent to the neighboring government. The immense forests of the country yield wood for fuel, and timber for the construction of the barges which, during summer, are floated down the rivers, freighted with the products of the mines. Three-fourths of the government are covered by forest; hardly above a twelfth is yet under the plough. The numerous works and factories employ over 100,000 hands, and recently their annual produce was estimated at £6,000,000, of which a third was the value of iron. Here, also, is a platina mine, said on good authority to be the richest in the world. The iron of P. is famous all over Europe. The commerce of the government is very considerable. The fair of Irbit (q. v.) is, after that of Nijni-Novgorod, the most important of the Russian empire. The transit trade, however, is much more considerable than the local trade. The great highway from Siberia to European Russia passes through P., and the government communicates by means of the Volga, Petchora, and the Obi, with the Baltic, White, and Caspian Seas. The central administration of mines has its seat in Ekaterinburg.

The government of P. once formed a portion of the ancient Biarmia, inhabited in the earliest historical times by Finnish tribes, and even then famous for the commerce which it carried on, especially with Asia. In the 11th c., it became connected commercially with the principality of Novgorod, which, little by little, conquered and took possession of the country. At the close of the 15th c., both it and Novgorod were annexed to the territories of the Prince of Moscow, and about the same time the Christian religion was introduced.

PERM, a town of European Russia, capital of the government of the same name, on the Kama, 1357 miles east-south-east of St. Petersburg. It was founded in 1729, under the name of the Egotinsky copper-work, and was the first colony in the government from which it derives its name. It is not in itself important

for its commerce, but it is the seat of a most extensive transit trade. Here goods floated down the Tshousovaia from the Ural Mountains, are transferred to larger vessels, and forwarded by the Kama and Volga past Nijni-Novgorod and Rybinsk, and thence to St. Petersburg. Goods from the sources of the Kama, metals, corn, tallow, and leathers, as well as Siberian and Chinese articles, are also sent from P. to the Russian interior, and to Europe generally. Near the town is a large cannon-foundry, possessing one of the largest steam-hammers in the world. Pop. (1880) 22,288.

PE'RMIAN, MAGNE'SIAN LIMESTONE, or DIAS group, is the lower division of the New Red Sandstone rocks, which were separated, chiefly on palæontological grounds, from the upper portion, and being, in 1841, without a collective name, were called Permian by Murchison, because he found them largely developed in that portion of Russia which composed the ancient kingdom of Permia, or Biarmia. The name Magnesian limestone is given to them because of the predominant deposit; and Dias has been proposed by some German geologists, to correspond with Trias, the name universally accepted for the upper section of the New Red Sandstone series.

The Permian strata occupy in Russia an area twice the size of France, and contain an abundant and varied suite of fossils. They are also largely developed in Germany, and as they have been there carefully studied, and described by numerous geologists, the rocks of that country may be considered as the types of the group. They have been thus grouped: 1. Bunterschiefer. 2. Zechstein. 3. Kupferschiefer or Mergel. 4. Rothe-todtliegende.

The Bunterschiefer consists of red and mottled marl and sandstone, which have been separated from the Triassic Bunter Sandstein, because of the occurrence in them of fossils which have a palæozoic facies. The Zechstein is chiefly a compact limestone with beds of colored clays, and cellular magnesian limestone. The well-known Stinkstein belongs to this series; it is a dark-colored and highly bituminous limestone, which gives out an offensive odor when struck or rubbed. The name Zechstein (literally, minestone) was given to these beds, because they must be mined or cut through to reach the Kupferschiefer below. This latter is a marl slate, richly impregnated with copper pyrites, for which it was extensively wrought. It contains numerous beautifully preserved fossil fish belonging to the genera *Palæoniscus*, *Cælacanthus*, *Platysurus*, &c. The strange name of Rothe-todtliegende (red dead-layers) was given to a large deposit of red sandstone and conglomerate, by the miners, because the copper obtained from the beds above died out when they reached these red rocks.

The succession of rocks given, by Murchison as occurring in Permian, are easily co-related with those of Germany. They are (1), conglomerates and sandstones, containing the remains of plants; (2), red sandstones and shales, with copper ore and vegetable remains; and (3), sandstones grits, and fossiliferous limestones, with interstratified beds of marl and gypsum, the marls occasionally containing plants, and also seams of impure coal.

In England, the Permian rocks are somewhat extensively developed in Durham, where they have been described by Sedgwick and King. From this county, they continue in a narrow strip bordering the Carboniferous beds down the center of England, until they are lost near Nottingham. In Cheshire, Shropshire, Stafford, and Warwick, they underlie the salt-bearing triassic rocks. The Durham strata are grouped as follows:

- | | |
|---|-----------------------|
| 1. Concretionary and amorphous limestone | } = Bunterschiefer. |
| 2. Brecciated and pseudo-brecciated limestone | |
| 3. Fossiliferous limestone | } = Zechstein. |
| 4. Compact limestone | |
| 5. Marl slate | = Kupferschiefer. |
| 6. Inferior various-colored sandstone | = Rothe-todtliegende. |

The fractured bones and teeth of saurians found in the basement bed of the sixth group, were considered the earliest evidence of the existence of reptiles, until the discovery of the *Archegosaurus* in the Carboniferous rocks.

The known organic remains of this period are neither remarkable nor abundant. Many palæozoic forms became extinct within this period; among them are the remarkable *Sigillaria* and the *Neuropteris* of the coal-beds, the well-known brachiopod, *Producta*, and several genera of heterocercal-tailed fish. Some new forms appear, the most important of which are the labyrinthodont reptiles, which, though beginning in the upper Carboniferous beds, increase in number in the Permian, and reach their maximum development in the succeeding Triassic group.

PERMUTATIONS AND COMBINATIONS. A combination, in Mathematics, is a selection of a number of objects from a given set of objects, without any regard to the order in which they are placed. The objects are called elements, and the combinations

are divided into classes, according to the number of elements in each. Let the given elements be the four letters *a, b, c, d*; the binary combinations, or selections of two, are *ab, ac, ad, bc, bd, cd*—six in all; the combinations of three are *abc, abd, acd, bcd*—four in all; while there is only one combination of four, namely, *abcd*.

Permutation, again, has reference to the order of arrangement; thus, the two elements, *a* and *b*, may stand *a b* or *ba*, so that every combination of two gives two permutations; thus, the three elements, *a, b*, and *c*, may stand *abc, acb, bac, bca, cab, cba*,—one combination of three thus affording six permutations. The combinations of any order with all their permutations are called the *Variations*. Formulas are given in works of algebra for calculating the number of permutations or combinations in any given case. Suppose seven lottery-tickets marked 1, 2, 3, to 7, and that two are to be drawn; if it is asked, how many possible pairs of numbers there are, this is a question of the number of combinations of seven elements, *two* together, which is found to be 21. If we want to know how many times the same seven persons could sit down to table together, with a different arrangement each time, this is to ask how many permutations seven objects admit of, and the formula gives, $7 \times 6 \times 5 \times 4 \times 3 \times 2 = 5040$. The theory of probabilities is founded on the laws of combination. Thus, in the case of drawing two tickets out of seven, since there are 21 possible pairs, the chance or probability of drawing any particular pair is 1 in 21, or $\frac{1}{21}$. In working out questions in 'combinations,' advantage is often taken of the fact that whatever number of elements be taken from a group to form a combination, the number left gives the same number of combinations; thus the number of combinations of 10 elements *three* together, is the same as that of 10 elements *seven* together, &c.

PERN. See HONEY BUZZARD.

PERNAMBUCO, or RECIFE, the most eastern seaport of Brazil, stands at the mouths of the Biberibe and Capeberibe, in lat. $8^{\circ} 4' S.$, long. $34^{\circ} 52' W.$, 80 miles south of Parahiba. It is the greatest sugar-mart in Brazil, and is the third in commercial importance of the cities of the empire. It consists of 3 portions, connected by roads and bridges—*Recife* proper, the chief seat of commerce, on the peninsula; *S. Antonio*, the middle district, on an island between the peninsula and the mainland; and *Boa Vista*, on the mainland. The inner harbor, which has a depth of from 10 to 30 feet, is formed by a reef which extends along the coast at a distance of from a quarter to half a mile from the coast. This reef serves the purposes of a breakwater. Opposite the northern extremity of the city, there is an opening in the reef, resembling an artificial cut, and forming a passage of sufficient width to admit of the entrance of vessels drawing 16 feet of water. No port is more easily accessible than the outer harbor of Pernambuco. There is a light-house in the harbor, and it is defended by several forts. Formerly, the city was extremely dirty, the streets unpaved, and much inconvenience was suffered from want of a proper supply of water. Of late years, however, many improvements have been introduced; water-works have been erected, extensive and spacious quays formed along the margins of the rivers, and the streets have, in most instances, been paved and lighted. Numerous *collegios* and other educational institutions have been established, and the growing wealth and commercial prosperity of the city has been accompanied by an increasing degree of comfort and refinement. The principal exports are sugar, cotton, rum, hides, and dye-woods; the imports are woollens and cottons, hardware, silks, wines, &c. The annual values of exports and imports averaged about £2,000,000. Pop. 120,000.

PERNAMBUCO, a maritime province of Brazil, is bounded on the south-east by Bahia and Alagoas, and on the north-west by Piauhí, Ceara, and Parahiba. It contains 50,000 square miles, and has a population of 850,000. The coast is flat, and fringed with coral reefs, which render navigation dangerous. The chief river is the San Francisco, which forms the southern boundary, and includes the greater portion of the area of the province in its basin. The banks of this river comprise many rich, expansive meadows, and here the cattle are reared which, in the form of beef and hides, form an important article of export at the seaport of Pernambuco. Much of the cotton and sugar brought to the market of the capital is harvested about 800 miles inland, in regions fertilized by streams that rise at the base of the Santa Barbareta Hills, the first hill-range in this district that arrests the trade-wind from the Atlantic, laden with rain. The San Francisco Railway, 77½ m. long, has done much to encourage the cultivation of sugar and cotton. The province comprises immense tracts of rich and fertile soil, productive in sugar-cane, cotton, maize, fruits, vegetables, and medicinal herbs. From the forests, balsams, gums, and dye-woods are obtained. In 1878 there were in P. 466 primary and 25 grammar schools, with 17,175 pupils.

PERNAMBUCO WOOD. See BRAZIL WOOD.

PERNO'W (Germ. *Pernau*), a seaport of the Baltic Provinces, Russia, in the government of Livonia, stands on a sandy heath at the mouth of a river of the same name, on the Gulf of Riga, 102 miles north of the port of Riga, and 350 miles west-south-west of St. Petersburg by sea. The mouth of the river is so shallow that large vessels are obliged to anchor in the roads. The exports are chiefly flax, linseed, corn, and timber; the principal imports are salt and herrings. In 1866, 124 ships, of which 44 were English and 24 Prussian, entered the port. Pop. (1880) 12,918.

PERPENDICULAR. A straight line standing on another straight line is said to be perpendicular to that other when the angles it makes on both sides are equal (see ANGLE). A line is said to be perpendicular to a plane when it is at right angles to any line in that plane meeting it. Planes are said to be perpendicular to each other when any line in the one plane perpendicular to their common line of intersection is also perpendicular to all lines meeting it in the other plane.

The word 'perpendicular,' in common usage, refers to a direction at right angles to the surface of still water, and is synonymous with vertical.

PERPENDICULAR, the name given to the style of Gothic architecture in England which succeeded the Decorated Style. It prevailed from about the end of the 14 c. to the middle of the 16th c., and was thus contemporary with the Flamboyant Style in France. These styles have much in common, but they derive their names from the features peculiar to each. Thus, the Flamboyant (q. v.) is distinguished by the flowing lines of its tracery;

Nave of Winchester Cathedral.

whilst the Perpendicular is remarkable for its stiff and rectilinear lines. The lines of the window tracery are chiefly vertical, and the mullions are frequently crossed by horizontal bars. The mouldings are usually thin and hard. The same feeling pervades the other features of the style; the buttresses, piers, towers, &c., are all drawn up and attenuated, and present in their shallow recesses and meagre lines a great contrast to the deep shadows and bold mouldings of the earlier styles. The art of masonry was well understood during the Perpendicular period, and the vaulting was admirably built. Fan-tracery Vaulting (q. v.) belongs to this style. The depressed or four-center arch is another of its peculiar features. This arch, over doorways, has the mouldings generally arranged in a square form over the arch, with spandrels containing shields, quatrefoils, &c. Panelling was also much

used, the walls being frequently almost entirely covered with it, as in Henry VII.'s Chapel at Westminster. There are many well-known buildings of this style. Most of the colleges at Oxford and Cambridge belong to it, and in almost every cathedral and church of importance, there are some specimens of it. Open timber-roofs are very common in the Perpendicular Style, and are amongst the peculiar and beautiful features of the architecture of this country. The roof of Westminster Hall, built by Richard II., is the largest example ever erected.

PERPENDICULAR FORTIFICATION owes its origin to the Marquis de Montalembert, a distinguished French general, who published his work upon the subject in 1776. Vauban had, it was admitted, rendered the art of attack superior to that of defence. Montalembert strove to reverse this relation, and, in his endeavors, rejected entirely the bastion system of the older engineers. Instead of the occasional bastions, with intervening curtains (see FORTIFICATION), with which they surrounded their *enceinte*, he broke the whole polygon into salient and re-entering angles, the latter being generally right angles. Before the connected redans thus formed were counterguards of low elevation and ravelins, to which the approaches were through casemated *caponnières*. In the salient angle of each redan, he built a brick tower, 40 feet in diameter, twelve-sided, and four stories high. The second and third tiers were built for heavy guns, and the upper loopholed for musketry. In the center of the tower was a circular *réduit*, intended as a last refuge for the garrison. Montalembert maintained that from these towers every possible approach could be commanded, which to a great extent is true; but it must be also remembered that the greater space a gun commands, by so much the more is it raised above the plain, and rendered visible. These towers would have little chance against the rifled ordnance of the present day. Montalembert's system was violently attacked by the French engineers, but Carnot subsequently adopted it, with some modifications, and it enters largely into the modern German defensive works. The system has never, however, found favor with British engineers.

PERPETUAL CURE, a form of ecclesiastical benefice which grew out of the abuse of lay Impropriation (q. v.), the impropriator appointing a clergyman to discharge the spiritual functions of which he himself was not capable. The substituted clergyman, in ordinary cases, is appointed by the bishop, and called a vicar; but when no provision is made for a vicar, the impropriator appoints the clergyman, who is called a perpetual curate. The perpetual curate enters on his office without induction or institution, and requires only the bishop's license. Perpetual cures are also created by the erection and endowment of a chapel subject to the principal church of a parish. Such cures, however, are not benefices, unless endowed out of the fund called Queen Anne's Bounty. Churches so endowed are, by 2 and 3 Vict. c. 49, recognized as benefices. The district churches which have been erected under several recent acts are made perpetual cures, and their incumbents are corporations.

PERPETUAL MOTION, THE. According to Newton's First Law (see MOTION, LAWS OF), all unresisted motion continues for ever unchanged. Thus, *if friction could be avoided*, a top or a gyroscope spinning in vacuo is an instance of motion which would be unchanged for ever, and which, therefore, might be called perpetual. The motion of the sun in space, the earth's rotation about its axis, and numerous other common motions, are in this popular sense perpetual. [It is necessary to remark here, that even these motions are subject to retardation; for instance, those of the bodies of the solar system, by the resistance of the luminiferous medium, which we know to be matter, and which fills all space. This was remarked by Newton himself, for he says, 'the larger bodies, planets and comets, preserve their motions longer (than terrestrial objects), because they move in less resisting media.' The same cause influences the motion of the gyroscope, but in its case there is another retarding influence at work, due to the production of electric currents by the magnetism of the earth.] But this is not what is technically understood by the title *The Perpetual Motion*. It means an engine which, without any supply of power from without, cannot only maintain its own motion for ever, or as long as its materials last, but can also be applied to drive machinery, and therefore to do external work. In other words, it means a device for creating power or energy without corresponding expenditure. This is now known to be absolutely impossible, no matter what physical forces be employed. In fact, the modern physical axiom, the Conservation of Energy (see FORCE), founded on experimental bases as certain as those which convince us of the truth of the Laws of Motion, may be expressed in the negative, thus: *The perpetual motion is impossible*. Helmholtz's beautiful investigations regarding Conservation of Energy (referred to in FORCE), are founded on this axiom. So is the recent application, by Clausius, of Carnot's remarkable investigation of the 'Motive-power of Fire' to the

true Theory of Heat. Other instances will be mentioned at the end of the article.

The complete statement of the impossibility of procuring the perpetual motion with the ordinary mechanical arrangements, in which it was most commonly sought, is to be found in the *Principia* (q. v.), as a deduction from Newton's Third Law of Motion. The equivalent principle of Conservation of Energy is there stated in a manner which leaves nothing to be desired; although not given in anything like the modern phraseology. Yet it is usually said, in works on the Perpetual Motion, that De La Hire (in 1678) gave the first proof of its impossibility in ordinary mechanics. This proof, published long after Newton's, is by no means so complete, as it exposes only some of the more patent absurdities which had been propounded for the solution of the problem. It is certain, and worthy of particular notice, that Newton was far in advance of the greatest of his contemporaries and their immediate successors, in even the fundamental notions of mechanics. Thus, we find John Bernoulli seriously propounding a form of the perpetual motion, depending upon the alternate mixture, and separation by a filter, of two liquids of different densities; an arrangement which is as preposterous as the very common suggestion of a water-wheel which should pump up its own supply of water; and whose absurdity must be evident to any one acquainted with Newton's chapter on the Laws of Motion.

It is curious that, long before Newton's time, the physical axiom, that the perpetual motion is impossible, was assumed by Stevinus as a foundation for the science of Statics. This is particularly interesting when we compare it with the magnificent discoveries which have been evolved in our own day from the same principle applied to the physical forces generally, and not to gravitation alone, as contemplated by Stevinus. His process is as follows: Let an endless chain of uniform weight be passed round a smooth triangular prism ABC, of which the face BC is horizontal. The free portion of the chain BDC will hang in a symmetrical curve (CATENARY, q. v.), and its tension will therefore be the same at B and at C. Hence the other portion BAC of the chain will be free to move, unless the resolved part of the weight of AB, acting down the inclined plane AB, just balance that of the corresponding portion of the chain down AC. If these balance, the parallelogram of forces is proved; if not, one side will preponderate, and we shall evidently obtain the perpetual motion.

We will briefly sketch the history of the simpler part of the problem, where mechanical and hydrostatical arrangements alone are contemplated, and where the impossibility of procuring the perpetual motion had been completely shown by Newton.

The leading features of the various devices suggested as self-moving engines are three. 1. The machine being a combination of mechanical powers driven by weights, was to be constructed so as constantly to wind up those weights as they fell, and therefore to be constantly in the same circumstances as to power in each successive complete revolution. The ideal of this, in its simplest form, is that of a wheel moving about a horizontal axis, and so adjusting certain heavy sliding pieces on its surface, as to have always a preponderance on one particular side. 2. The type of the second class differs from that of the first only in the substitution of liquids for the weights in the first class, and the consequent introduction (often in most extravagant forms) of hydrostatical laws, which the inventors seem to have considered less certain and more pliable than the stern facts of common mechanics. 3. The machine depends on some natural power, such as rain, change of temperature, wind, fluctuations of the barometer, tides, &c. The consideration of the third class is very interesting, but we will defer it for a little.

Of the first class, the only machines that seem ever to have succeeded in permanently deceiving any but their inventors are those of the Marquis of Worcester and of Councillor Orffyreus. Contemporary with the former was Bishop Wilkins, who candidly and ingeniously points out the fallacies of various devices of his own, depending severally on weights, on magnets, and on Archimedes's screw. His first attempt seems to have been closely allied to that of the Marquis of Worcester, of whose engine we have no drawing, and only a very vague description. The following figures give us, however, some notion of its probable nature. The first is one of Wilkins's, the second that of Jackson, the third that of Merlin. Their construction is evident from the figures.

In all three, the attempt is by the sliding of the balls in their cells, or by the turning of the levers, to give the preponderance to the descending side of the wheel. But even the cuts show that, though the weights on the descending side are on the whole further from the axis of the wheel than those on the ascending side, *yet there are more balls on the latter than on the former side; and*

a careful examination, like that made by Wilkins, shows that their moments in opposite directions about the axis balance each other. With reference to the invention of the Marquis of Worcester—who is otherwise well known as one of the first to foresee, and even in part to realize experimentally, the advantage of steam

Merlin's Perpetual Motion.

as a motive-power—we find the following in his *Century of Inventions*: 'Advantageous Change of Centers.—To provide and make that all y^e weights of y^e descending syde of a wheele shal be perpetually further from y^e center, then those of y^e mounting syde, and yett equall in number and heft of y^e one syde as y^e other. A most incredible thing if not seene, butt tryed before y^e late King of happy and glorious memorye in y^e Tower by my directions, two Extraordinary Embassadors accompanying his Ma^{ty} and y^e D. of Richmond, D. Hamilton, and most part of y^e Court attending him. The wheele was 14 foote ouer, and 40 weights of 50 p^d apiece; S^r Wm. Belford, then Lieut^t of y^e Tower, and yett living can justify it with seuerall others; They all saw that noe sooner these great weights passed y^e Diameter Line of y^e vpper syde but they hung a foote further from y^e center, nor no sooner passed the Diameter Line of the lower syde, butt they hung a foote nearer; bee pleased to judge y^e consequence.'*

The machine of Orffyreus, by which 'S Gravesande was completely taken in, so much so, that he wrote to Newton expressing his belief that the perpetual motion was really found, consisted of a large wheel or drum covered with canvas, to prevent the interior from being seen, and rotating about a thick horizontal axle. This machine, when set agoing in either direction, moved with accelerated speed till it reached a rate of twenty-five turns in a minute; and on one occasion was sealed up by the Elector of Cassel for two months, and at the expiration of that time found to be moving as rapidly as ever. This, like the celebrated automaton chess-player, was evidently a case of clever imposition; and but for its strange effect on 'S Gravesande, would probably have been forgotten long ago. Tricks of this kind, more or less ingenious, such as that of Spence of Linnlithgow (1818), which many of our readers may recollect, are still common, especially in America.

Bishop Wilkins's First Form.

Bishop Wilkins's third form is a good example of the second

* See Harleian MS., No. 2428, in the British Museum.

class of contrivances above mentioned. Its construction will be readily understood from the annexed cut. The water-wheels, driven by the descending water, are intended to turn the Archimedean screw, so as constantly to replenish the tank above. Wilkins's calm investigation of the reasons why his device will not succeed, is very interesting and creditable.

As a contrast, let us take a case of special absurdity, that of Norwood. In the figure, it is supposed that, as the weight of the water or mercury in the large vessel immensely exceeds that in

Jackson's Perpetual Motion.

the neck, it will preponderate, and drive the liquid through the spout into the vessel again; thereby furnishing, not only an admirable perpetual motion, but a conclusive disproof of one of the fundamental laws of Hydrostatics.

The second of Wilkins's cases is an instructive one. It depends on magnetism, and will be readily understood from the cut.

Bishop Wilkins's Third Form.

AB is a loadstone, which draws the iron ball C up the incline plane to E, where there is a hole through which the ball falls down the curved incline, pushes open a trap at F, and is dragged again up the plane by the loadstone. The error of this is the neglect of the action

Norwood's Perpetual Motion.

of the loadstone on the falling ball. There would be an admirable case of the perpetual motion if we could remove or annihilate (without expenditure of work) the action of the loadstone during the descent. Unfortunately, the law of magnetic attraction is the same as that of gravitation, and what is impossible with the

one, must be equally so with the other. A good illustration of this is Addeley's Perpetual Motion, represented in the annexed sketch. The spokes projecting from the wheel are magnets, whose south poles are all turned from the center. These are attracted by the north poles (N), and repelled by the south poles (S) of four fixed magnets; and blocks of wood (A) are inter-

Bishop Wilkin's Second Form.

posed, to prevent magnetic action where it would tend to stop the machine! If it were possible to find a substance which would deal with gravitation or magnetism as an opaque body does with light (casting a shadow), the perpetual motion would be obtained with the greatest ease.

It would be tedious and unprofitable to go through the various physical forces, showing how a misconception of their laws has

Addeley's Perpetual Motion.

led to hundreds of patented schemes for the production of perpetual motion. We may merely hint at magneto-electric machines turned by electro-magnetic engines, to which they supply the electric currents; electric machines, driven by a gas-engine, the fuel for which is supplied by the decomposition of water by the electricity produced, &c.; the absurdity of all of which may be imagined from the perfectly analogous case of a steam-engine to which heat might be supposed to be supplied by the friction of bodies driven by the engine itself. An excellent example of this absurdity is furnished by the writings of one of our ablest geologists. He considers that the internal heat of the earth may be due to chemical combination, that the heat so produced may develop thermo-electric currents, and that these in their turn may decompose the compounds formed, so that the process may go on indefinitely.

But the third class of attempts above described merits a few words. It certainly does not give the perpetual motion, but it is capable of furnishing prime-movers which will work uninterruptedly for perhaps hundreds of thousands of years. This is done, however, as we should expect, at the expense of other stores of energy in the universe. Thus, the tide-wheel, or tidal engine, a little-used but most effective source of power, derives its energy entirely from the earth's diurnal rotation. Engines driven by collected rain-water, such as mill-wheels, &c., and others driven by power stored up from winds, &c., depend upon energy radiated from the sun, mainly in the form of heat. None of these can, therefore, in strictness be called the perpetual motion, since the energy of the earth's rotation, or of the sun's heat, is drawn upon in their production.

But the complete proof of the impossibility of procuring the

perpetual motion by any arrangement whatever, involving any known forces, was arrived at mainly by the experiments of Joule (q. v.), who showed that the principle of the Conservation of Energy extends, not alone to the forces for which it was enunciated by Newton, but to every known form of physical action. The date 1840—1845 may thus be said to have finally settled this long-disputed question; at all events, until new forms of physical forces may happen to be discovered; and we are now in a position to do generally, what was wisely done by the French Academy in 1775 for ordinary mechanical contrivances alone—viz., refuse to consider any scheme whatever which pretends to give work without corresponding and equivalent expenditure. The language in which this decision of the French Academy is recorded (*Histoire de l'Académie*, 1775) is well worthy of being quoted, for its calm scientific clearness and brevity, and for its present applicability to physical science in general: 'The construction of a perpetual motion is impossible. Even if the effect of the motive power were not in the long run destroyed by friction and the resistance of the medium [in which the motion takes place], this power could produce merely an effect equivalent to itself. In order, therefore, to produce a perpetual effect from a finite cause, that effect must be infinitely small in any finite time. Neglecting friction and resistance, a body to which motion has been given will retain it forever; but only on condition of its not acting on other bodies, and the only perpetual motion possible, on this hypothesis (which, besides, cannot occur in nature), would be useless for the object which the devisers of perpetual motions have in view. This species of research has the inconvenience of being costly; it has ruined many a family; and numerous mechanics, who might have done great service, have wasted on it their means, their time, and their talents.'

'These are the principal motives which have led the Academy to its decision. In resolving that it will no longer notice such speculations, it simply declares its opinion of the uselessness of the labors of those who are devoted to them.'

It has been asserted that the infatuation of the perpetual motionists, who (as may be seen by a glance at the specifications of patents in Britain, France, Belgium, America, &c.) are perhaps more numerous now than ever, is due to two causes—one, the idea that the perpetual motion is a lost, but recoverable invention; the other, that some immense government reward has been for years laid aside for the successful discoverer. But, unhappily, these ideas are as fallacious as the grand delusion itself; and any one who, in the present state of science, allows himself to be carried away by this fascinating inquiry, loses his time and wastes his talents, more hopelessly than even a 'squarer of the circle.'

In conclusion, we may mention a few of the cases already hinted at, in which the impossibility of the perpetual motion formed the basis of an investigation. These will show the great use which may be made of even a negative proposition. Helmholtz has shown from it that the ultimate particles of matter must exert upon each other forces, whose direction is that of the line joining each pair of particles, and whose magnitude depends solely on their distance. J. Thompson employed it to show that the freezing-point of water is lowered by pressure, as otherwise work might be created by the freezing of ice-cold water. W. Thomson has employed it to show that a diamagnetic (see DIAMAGNETISM) body does not take the opposite magnetism to iron, when in similar circumstances; for if it did, and if, like iron, it took time for the full development of the action, a perpetual motion might be produced.

The literature of this subject is very extensive, but scattered mainly through Patent Records and ephemeral pamphlets. The *Journal des Savants*, and Montucla's *Histoire des Mathématiques* may be consulted; but especially we would refer the curious to an interesting work by Mr. Dircks (of Patent-Ghost notoriety) entitled *Perpetuum Mobile* (Spon, London, 1861); to which we have been indebted for some of our historical notices. The tenor of the work is such that we cannot easily discover whether the author is a perpetual-motionist or not; but, however this may be, it is extremely complete and interesting as a history.

PERPETUITIES, LAW AGAINST, consists in a rule adopted in England to the effect that property cannot be tied up for a period longer than the lives of some parties already in existence, and 21 years more. Those who have the power of disposing of their property have often attempted to regulate the succession of their estate at distant periods. Such was the object of the original practice of entailing property, and so enforcing the devolution of property on a certain series of heirs to the remotest generations. This power of testators was always looked upon with jealousy, as tending to embarrass future dealings with the property, and frustrate the purposes for which property is established. So early as the reign of Edward IV., a decision was come to by the courts in Taltarum's case, which had the effect of allowing the first tenant in tail in remainder, on arriving at majority, to disentail the estate at discretion. Hence, in England, there has

been ever since no mode of settling property in any way so as to tie it up beyond the life of the first who takes an estate of freehold, and the tenure of the tenant in tail next in remainder—i. e., the lives of persons in existence, and 21 years more. This principle applies not only to land, but to personal property. As to the accumulation of the income of property, an attempt was made by the late Mr. Thellusson to create an immense fortune by directing the income of his property to be accumulated during the lives of all his children, grandchildren, and great-grandchildren, who were living at the time of his death, for the benefit of some future descendants, to be living at the death of the survivor. The probable amount of the accumulated fund was expected to be 19 millions. The will was in great measure defeated by the existing law, but in consequence of so conspicuous an attempt, an act of parliament was passed, called the Thellusson Act (39 and 40 Geo. III. c. 98), which in future forbids the accumulation of income for any longer time than the life of the grantor or settlor, or 21 years from his death. In Scotland, so far from the above doctrines having been early adopted, the contrary doctrine was established. See **ENTAIL**.

PERPIGNAN, a town of France, and a fortress of the first rank, capital of the department of Pyrénées-Orientales, on the right bank of the river Tet, 5 miles from the Mediterranean, and 40 miles by railway south of Narbonne. It commands the passage by the Eastern Pyrenees from Spain into France, and is defended on the south by a citadel and by ramparts flanked with bastions, and protected by raised works. The works underwent a thorough repair in 1823, and P. now ranks as one of the first strongholds in France. Its appearance is exceedingly picturesque. From a distance, its houses are seen in the midst of a forest of orchards; and a closer examination shows a collection of narrow streets, covered with awnings; houses of semi-Moresque construction, with wooden balconies and courts, and other evidences of Spanish influence. The cathedral, a massive building, begun in 1324; the belfry of St. Jacques and the Castiller (now used as a military prison), with its battlements and machicolations, give character to the town. P. contains barracks for 5000 men, a council-house, palace of justice, mint, a college, numerous schools, museums, and scientific societies. *Good vin ordinaire* (red) is grown in the vicinity; woollen cloths, playing-cards, leather, &c., are manufactured, and there is a good trade in wine, brandy, wool, cork-bark, and silk. Pop. (1872) 20,011; (1876) 24,379.

P., as capital of the former county of Roussillon, remained long in the hands of the kings of Aragon, and in 1349, King Pedro founded a university here. In 1642, it was taken by Louis XIII.; and since that time, the town itself, together with the county of Roussillon, has remained in the possession of the French.

PERRAULT, CHARLES, a French writer, born at Paris, 12th January 1628, was the son of an advocate, and received a good education. In 1651, he became a member of the Paris bar, and obtained a considerable measure of success as a pleader; but having made the acquaintance of the minister Colbert, he was elonged diverted from the practice of his profession by receiving the appointment of Controller-general of the Royal Buildings. In 1671, the influence of Colbert procured for him an entrance into the French Academy, into which learned body he introduced several important reforms. What first made his name well known was his famous controversy with Boileau regarding the comparative merits of the ancients and moderns, which originated in a poem of P.'s, entitled *Le Siècle de Louis le Grand*, read before his confrères of the Academy, and intended to prove that modern authors were superior to Homer, Herodotus, Plato, Aristotle, Virgil, &c. It was followed up by an elaborate and methodically written *Parallèle des Anciens et des Modernes* (4 vols. 1688—1698), which, though an able and learned performance, is a complete failure in its logic. Boileau was his keenest opponent, and fiercely, not to say rudely, assailed him in his *Réflexions sur Longin*, to which P. replied with equal acrimony, but not with equal wit, in his *Apologie des Femmes* (1694). One good effect of this quarrel was to turn P.'s attention still more closely and critically to his contemporaries, the result of which was an admirable work *Hommes Illustres du Siècle de Louis XIV.*, containing 200 critical biographies. But the work that has far more than any other preserved his name is his *Contes des Fées*, or Fairy Tales. See **NOVELS**. The grace, liveliness, and ingenious child-like fancy displayed in these charming compositions, are beyond all praise, and when we remember that their author was far advanced in years when he wrote them, the feat seems miraculous. 'Second childhood' is not always so like the 'first,' as that of P. seems to have been. P. died 16th May 1708.

PERRY, an agreeable beverage made by fermenting the juice of pears. It is extensively made in Worcestershire, Gloucestershire, Herefordshire, and Devonshire, and forms, with cider, the chief diet-drink of those districts. It contains from five to nine per cent. of alcohol. The best pears for making perry are those which from their rough taste are least agreeable for eating.

PE'RSEA. See **AVOCADO PEAR**.

PERSECUTIONS, THE TEN, of the Christian Church, is the name by which are known in ecclesiastical history certain periods of special severity exercised towards the rising community of Christians, for the purpose of compelling them to renounce their new creed, and to conform to the established religion of the empire. The Christian community were at all times regarded with suspicion and dislike in the Roman empire—the constitution of Rome not only being essentially intolerant of those new religions which, like the Christian, were directly aggressive against the established religion of the state, but being particularly hostile to private associations and private assemblages for worship, such as those which every Christian congregation by its very nature presented; and thus there are very few periods, during the first three centuries, in which it can be said that the church enjoyed everywhere a complete immunity from persecution. But the name is given particularly to certain periods when either new enactments were passed against Christianity, or the existing ones were enforced with unusual rigor. The notion of *ten* such periods is commonly accepted almost as an historical axiom; and it is not generally known that this precise determination of the number is comparatively recent. In the 4th c., no settled theory of the number of persecutions seems to have been adopted. Lactantius reckons up but six; Eusebius does not state what the number was, but his narrative supplies data for nine. Sulpicius Severus, in the 5th c., is the first who expressly states the number at *ten*; but he only enumerates nine in detail, and in completing the number to *ten*, he adds the general persecution which, at the coming of Antichrist, is to precede the end of the world. The fixing of *ten* as the number seems to have originated in a mystic allusion to the *ten horns* of the beast in the Apocalypse (xvii. 12).

It need hardly be said, however, that this is only a question of words, the diversity of enumeration arising from the different notions attached by the several historians to the designation *general*. If taken quite strictly to comprise the entire Roman empire, the number must fall below *ten*; if used more loosely of local persecutions, the number might be very largely increased. The *ten* persecutions commonly regarded as general are the following: the persecution under Nero, 64 A.D.; under Domitian, 95 A.D.; under Trajan, 107 A.D.; under Hadrian, 125 A.D.; under Marcus Aurelius, 165 A.D.; under Septimius Severus, 202 A.D.; under Maximinus, 235 A.D.; under Decius, 249 A.D.; under Valerianus, 257 A.D.; under Diocletian 303 A.D. The extent and the duration of some of these have been the subject of considerable controversy, and indeed an animated discussion was maintained for a long period as to the probable total number of victims in the pagan persecutions of the church. Such controversies are beyond the scope of this publication. It is quite certain that there have been exaggerations on the Christian as well as on the adverse side; but it has been shown beyond the possibility of doubt, and the most recent explorations have confirmed the arguments, that the data on which the estimates of Dodwell and Gibbon, the most prominent advocates of the theory of the small number, were founded, were uncertain, and even fallacious; and that, not to speak of the many victims of the constantly recurring local violence, the number who fell in each of the above-named persecutions was both large in itself, and spread, in most cases, over a considerable extent of the Roman empire. The most violent, as well as the most widely-spread of these persecutions, were those under Nero, Trajan, Maximinus, Decius, and Diocletian. The last-named, though called by Diocletian's name, was in reality far less the work of that emperor than of his colleague Galerius; but it was extremely cruel, and, with occasional interruptions, continued from the year 303 down to the victory of Constantine over Maxentius—a period of nearly ten years.

PERSE'POLIS (Persian City), the Greek translation of the lost name of the capital of ancient Persia (*Parsa-Karta*?), was situated on the river Araxes (Berdemir), to the east of the river Medus (Polvat, or River of Murghab), in the plain of Merdusht, about 35 miles to the north-east of Shiraz, on the road to Ispahan. A certain number of most remarkable ruins is all that now remains of that city, with which, according to ancient writers, 'no other city could be compared either in beauty or in wealth,' and which was generally designated 'The Glory of the East.' Darius Hystaspes, Xerxes, Artaxerxes, and other Achæmenides, each in his turn contributed towards its aggrandizement. Alexander the Great, in his march of conquest, is said to have destroyed P. completely; but this must probably only be understood to apply to some of the chief palaces. It may also be presumed that after the fall of the Achæmenides, that extension of the original town (afterwards known, and important in history up to within a recent period, as Istakhar), on which were situated the royal edifices and temples used as the royal treasuries up to the time of Epiphanes, gradually fell into decay. The situation of these structures, overlooking the vast luxuriant plain of Merdusht, is described in terms of rapturous enthusiasm by every traveler

from Chardin to our own day. Three groups are chiefly distinguishable in the vast ruins existing on the spot. First, the Chehel Minâr (Forty Pillars), with the Mountain of the Tombs (Rachmed), also called Takht-i-Jamshîd or the structure of Jamshîd, after some fabulous ancient king, popularly supposed to be the founder of Persepolis. The next in order is Naksh-i-Rustam, to the north-west, with its tombs; and the last, the building called the Haram of Janshîd.

The most important is the first group, situated on a vast terrace of cyclopean masonry at the foot of a lofty mountain-range. The extent of this terrace is about 1500 feet north-by-south, and about 800 east-by-west, and it was, according to Diodorus Siculus, once surrounded by a triple wall of 16, 32, and 60 cubits respectively in height, for the triple purpose of giving strength, inspiring awe, and defence. The whole internal area is further divided into

Ruins of Persepolis.

(Copied from Fergusson's *Palaces of Nineveh and Persepolis Restored*.)

three terraces—the lowest towards the south; the central being 800 feet square, and rising 45 feet above the plain; and the third, the northern, about 550 feet long, and 35 feet high. No traces of structures are to be found on the lowest platform; on the northern, only the so-called 'Propylæa' of Xerxes; but the central platform seems to have been occupied by the foremost structures, which again, however, do not all appear to have stood on the same level. There are distinguished here the so-called 'Great Hall of Xerxes' called (Chehel Minâr, by way of eminence), the Palace of Xerxes, and the Palace of Darius, towering one above the other in successive elevation from the ground. The stone used for the buildings is dark gray marble, cut into gigantic square blocks, and in many cases exquisitely polished. The ascent from the plain to the great northern platform is formed by two double flights, the steps of which are nearly 22 feet wide, 34 inches high, and 15 inches in the tread, so that several travelers have been able to ascend them on horseback. What are called the Propylæa of Xerxes on this platform are two masses of stonework, which probably formed an entrance-gateway for foot-passengers, paved with gigantic slabs of polished marble. Portals, still standing, bear figures of animals 15 feet high, closely resembling the Assyrian bulls of Nineveh. The building itself, conjectured to have been a hall 32 feet square, is, according to the cuneiform inscriptions, as interpreted by Rawlinson, the work of Xerxes; the inscription reads as follows:

'The great god Auramajda, he it is who has given this world, and who has given life to mankind, who has made Xerxes king, both king and lawgiver of the people. I am Xerxes the king, the great king, the king of kings, the king of the many-peopled countries, the supporter also of the great world, the son of King Darius, the Achæmenian.

'Says Xerxes the king, by the grace of Auramajda, I have made this gate of entrance; there is many another nobler work besides this Persepolis which I have executed, and which my father has executed'; &c.

An expanse of 162 feet divides this platform from the central one, which still bears many of those columns of the Hall of Xerxes from which the ruins have taken their name. The staircase leading up to the Chehel Minâr, or Forty Pillars, is, if possible, still more magnificent than the first; and the walls are more superbly decorated with sculptures, representing colossal warriors with spears, gigantic bulls, combats with wild beasts, processions and the like; while broken capitals, shafts, pillars, and countless fragments of buildings, with cuneiform inscriptions, cover the whole vast space of this platform, 350 feet from north to south, and 380 from east to west. The Great Hall of Xerxes, perhaps the largest and most magnificent structure the world has ever seen, is computed to have been a rectangle of about 300—350 feet, and to have consequently covered 105,000 square feet, or 2½ acres. The pillars were arranged in four divisions, consisting of a center group six deep every way, and an advanced body of twelve in

two ranks, the same number flanking the center. Fifteen columns are all that now remain of the number. Their form is very beautiful. Their height is 60 feet, the circumference of the shaft 16, the length from the capital to the torus, 44 feet. The shaft is finely fluted in 52 divisions; at its lower extremity begin a cincture and a torus, the first, two inches in depth, and the latter one foot, from whence devolves the pedestal, shaped like the cup and leaves of the pendent lotus, the capitals having been surmounted by the double semi-bull. Behind the Hall of Xerxes was the so-called Hall of Hundred Columns, to the south of which are indications of another structure, which Fergusson terms the Central Edifice. Next along the west front stood the Palace of Darius, and to the south the Palace of Xerxes, measuring about 86 feet square, similarly decorated, and of similar grand proportions.—For a more minute description, we refer to the travels of Niebuhr, Ker Porter, Rich, &c.; to Fergusson's *Palaces of Nineveh and Persepolis Restored*, to Vaux's *Nineveh and Persepolis*, and to Rawlinson's *Five Great Monarchies*. See also CYRUS, DARIUS, XERXES, CUNEIFORM, and PERSIAN ARCHITECTURE.

PERSEUS, also PERSES, the last king of Macedonia, was the eldest son of Philip V., and was born in the latter part of the 3d c. B.C. He was trained to a military life from his earliest years, and after bringing about the death of his younger brother, Demetrius, who was a favorite both with the Macedonians and the Romans, he succeeded his father on the throne 179 B.C. Philip had long foreseen that a contest between Rome and Macedon was inevitable, and he had carefully prepared for it, so that P., on his accession, found himself forearmed. Meanwhile, he governed Macedon with great prudence and moderation, and became decidedly popular with his subjects and neighbors. Seleucus IV. (Philopator) gave him his daughter Laodice in marriage; Prusias, the Bithynian king, married his sister; the Greek states looked favorably on his projects, and his envoys were well received even at Carthage. The Romans took the alarm, and—after some delusive negotiations—sent an army into Thessaly (171 B.C.). The war lasted four years; in the first three, the advantages were so little on the side of the Romans, that there was a widespread feeling in P.'s favor in the countries bordering on the Levant and the Archipelago. In the beginning of the fourth campaign (168 B.C.), L. Æmilius Paulus arrived, and took command of the Roman forces. A great battle was fought at Pydna (June 22), in which the army of P. was utterly routed. The king himself was soon afterwards forced to surrender, and conveyed to Rome, where he adorned the triumph of the conqueror. He died in captivity at Alba, a few years later.

PERSEUS, in Grecian Mythology, the son of Zeus and Danaë (q. v.), and grandson of Acrisius. He was brought up at Seriphos, one of the Cyclades, where Polydectes reigned, who, wishing to get rid of him for private reasons, sent him, when yet a youth, to bring the head of the Gorgon Medusa, on the pretence that he wanted to present it as a bridal gift to Hippodamia. P. set forth under the protection of Athene and Hermes, the former of whom gave him a mirror, by which he could see the monster without looking at her (for that would have changed him into stone); the latter, a sickle; while the nymphs provided him with winged sandals, and a helmet of Hades, or invisible cap. After numerous wonderful adventures, he reached the abode of Medusa, who dwelt near Tartessus, on the coast of the ocean, and succeeded in cutting off her head, which he put into a bag, and carried off. On his return, he visited Ethiopia, where he liberated and married Andromeda, by whom he subsequently had a numerous family, and arrived at Seriphos in time to rescue his mother from the annoyance of the too ardent addresses of Polydectes, whom, along with some of his companions, he changed into stone. After this, he went to Argos, from which Acrisius fled to Thessaly, and P. assumed the vacant throne. But this, like many other details of the myth, is differently narrated. P. was worshipped as a hero in various parts of Greece and, according to Herodotus, in Egypt too. In ancient works of art, the figure of P. much resembles that of Hermes.

PERSEVERANCE OF SAINTS, a doctrine necessarily resulting from the most essential parts of the Calvinistic system, and therefore held by almost all who adopt the Calvinistic or Augustinian doctrines. It is advocated not only by arguments from other doctrines, as those of election, atonement, the intercession and mediatorial dominion of Christ, imputed righteousness, and regeneration, but also from many texts of Scripture, as those which declare *eternal life* to be always connected with believing, and those which encourage the believer to depend on the faithfulness, love, and omnipotence of God. To an objection very commonly urged against it, that it tends to make men careless concerning virtue and holiness, its advocates reply, that this objection is only valid against a doctrine very different from theirs, the true doctrine of Perseverance of Saints being one of perseverance in holiness, and giving no encouragement to a confidence of final

salvation which is not connected with a present and even an increasing holiness.

PERSHORE, a market-town in the county of Worcester, and 9 miles south-east of the city of that name, on the Avon. It contains two churches—that of St. Andrew's, small and ancient; and the church of the Holy Cross, in Norman and Early English, with a lofty square tower. This church is the only remaining portion of the ancient abbey-church of the same name. Pop. (1881) 2578, who are employed in wool-stapling, in manufacturing agricultural implements, and in raising fruits and vegetables for the markets of the large manufacturing towns in the vicinity.

PERSIA, called by the natives **IRAN** (see **ARYAN RACE**), the most extensive and powerful native kingdom of Western Asia, is bounded on the N. by the great plain of Khiva, the Caspian Sea, and the Trans-Caucasian provinces of Russia; on the E. by Bokhara, Afghanistan, and Beloochistan; on the S. by the Strait of Ormuz and the Persian Gulf; and on the W. by Asiatic Turkey. It extends 900 miles from east to west, and 700 miles from north to south, and has an area of about 648,000 miles. It consists for the most part of a great tableland, or elevated plateau, which in the center and on the east side is almost a dead-level; but on the north, west, and south is covered with mountain-chains. The province of Azerbaijan, in the north-west, is almost wholly mountainous. From its southern boundary, the majestic range of the Elburz runs eastward, following the line of the Caspian coast at a distance varying from 12 to 60 miles. On reaching Astrabad, the mountains sink into ridges of lower elevation, one of which joins the Paropamisus in Afghanistan. A hill country lies north of this line; it terminates in the Daman-i-koh chain, which sinks abruptly to the low plain of Turkestan. South and east of Azerbaijan, a broad mountain-belt traverses P. from north-west to south-east, the chains and valleys of which it consists lying in the same direction. To this region belong the mountains running from Hamadan to Shiraz, many of the peaks of which are clad with perpetual snow; and the Zagros Mountains and Pushti Kuh on the western frontier.

The Persian mountains are mostly primitive; granite, porphyry, felspar, and mountain-limestone enter largely into their composition. They also exhibit indications of volcanic action—Taftan, south of Lake Zirreh, or Zamoan, being an active, and Demavend an extinct volcano; and the destructive earthquakes which are still of frequent occurrence in the north and north-west of P., indicate the presence of subterranean fires. The Persian plateau, which lies in an angle formed between these mountains, and spreads eastward to the plateau of Afghanistan, ranges from 2000 to 5000 feet above sea-level, the lowest portion being the Great Salt Desert in the south-west of Khorassan, which has 2000 feet of elevation above the sea; while the average elevation of the whole plateau above the sea is about 3700 feet.

Almost the whole of Khorassan (q. v.), the north half of Kerman (q. v.), the east of Irak-Ajemi (q. v.), which form the great central plain, and detached portions of all the other provinces, with the exception of those on the Caspian Sea, forming more than three-fourths of the surface of P., are desert. In some parts of this waste, the surface is dry, and produces a scanty herbage of saline plants; in other parts, it is covered with salt marshes, or with a dry, hard, salt crust, sometimes of considerable thickness, which glitters and flashes in the sunlight, forcing the traveler on these inhospitable wastes to wear a shade to protect his eyes; but by far the greater portion of this region consists of sand, sometimes so light and impalpable as to be shifted hither and thither by the slightest breeze. This great central desert contains a few oases, but none of great extent. A narrow strip of low and level country extends along the shores of the Persian Gulf and the Strait of Ormuz. It consists of a succession of sandy plains, occasionally interrupted by a plantation of palms near the scanty rivulets which traverse it. It is called Dushistan, or Gurmish—that is, the warm region, in opposition to the mountainous districts, called Sirhud, or the cold country.

Although so much of P. is desert, some parts of the country are of exceeding fertility and beauty: the immense valleys, some of them 100 miles in length, between the various ranges of the Kerman Mountains, abound with the rarest and most valuable vegetable productions. Great portions of the provinces of Fars, Khuzistan, Ardelan, and Azerbaijan have been lavishly endowed by nature with the most luxuriant vegetation; while the provinces of Ghilan and Mazanderan, which lie between the Elburz and the Caspian Sea, and the southern slopes of the Elburz, are as beautiful as wood, water, and a hot climate can make them—the mountain-sides being clothed with trees and shrubs, and the plain, 300 miles long by from 5 to 30 miles wide, studded with mulberry plantations, rice fields, vineyards, orchards, orange grounds, and sugar and cotton plantations.

Rivers.—P. has hardly one river that can properly be termed navigable, though some of them are several hundred miles in length, and of great width and volume of water; among those of

sufficient importance to deserve mention is the Karun, which rises in the mountains to the south of Ispahan, and falls into the Shat-el-Arab, near Mohammerah. The rivers which flow to the southward receive, in the latter part of their course, few tributaries, and fertilize only a narrow strip of land on each side of them, except when their waters are applied, by means of canals or other works, to the artificial irrigation of the soil. This mode of increasing and extending the productive powers of the country was much employed in ancient times; but the constant change of masters, and the never-ending disturbances under which P. has so long suffered, led to the neglect of the practice, and most of these monuments of the architectural skill and laborious industry of the ancient Persians are now ruinous.

Lakes.—P., as a natural consequence of the nature and situation of its surface, abounds with saline lakes, and there are nearly thirty of them having no visible outlets. The chief lake is Lake Urumiah (q. v.), in Azerbaijan. Lake Bakhtegan, in the east of Fars, the receptacle for the drainage of the northern half of that province, is about 60 English miles in length by 9 in breadth. Lake Shiraz (q. v.) is much smaller. Part of Lake Zirreh is now included in the frontier of P., but it may still be considered as chiefly belonging to Afghanistan.

Climate and Products.—The climate is necessarily very varied. What the younger Cyrus is reported to have said to Xenophon regarding the climate, 'that people perish with cold at the one extremity, while they are suffocated with heat at the other,' is literally true. P. may be considered to possess three climates—that of the southern Dushistan, of the elevated plateau, and of the Caspian provinces. In the Dushistan, the autumnal heats are excessive, those of summer more tolerable, while in winter and spring the climate is delightful. On the plateau, the climate of Fars is temperate. About Ispahan, the winters and summers are equally mild, and the regularity of the seasons appears remarkable to a stranger. To the north and north-west of this, the winters are severe. The desert region of the center and east, and the country on its border, endure most oppressive heat during summer, and piercing cold in winter. The Caspian provinces, from their general depression below the sea-level, are exposed to a degree of heat in summer almost equal to that of the West Indies, and their winters are mild. Rains, however, are frequent and heavy, and many tracts of low country are marshy and extremely unhealthy. Except in the Caspian provinces, the atmosphere of P. is remarkable above that of all other countries for its dryness and purity.

The cultivated portions of P., when supplied with moisture, are very fertile, producing an immense variety of crops. The chief cultivated products are wheat (the best in the world), barley, and other cereals, cotton (of which, according to the statement of the Persian ambassador at London in 1861, enough could be grown in the southern provinces to supply the manufactories of Western Europe), sugar, rice, and tobacco. The vine flourishes in several provinces, and the wines of Shiraz are celebrated in Eastern poetry. Mulberries are also largely cultivated, and silk is one of the most important products of the kingdom.

The forests of the Elburz abound with wild animals, as wolves, tigers, jackals, boars, buffaloes, foxes, and the Caspian cat. Lions and leopards also abound in Mazanderan. Among domestic animals, the horse and camel hold the first place. The horses have always been celebrated as the finest in the East: They are larger and more handsome, but less fleet than the Arabian horses. The Caspian rivers abound with fish, especially sturgeon, great quantities of which are cured and exported to Russia. The mineral products of P. are insignificant, with the sole exception of salt. Iron is abundant in Azerbaijan, but is little worked; copper occurs in considerable quantity in the mountains of Mazanderan and Kerman; and lead, antimony, sulphur, and naphtha also abound. Dr. Fulze, of the Imperial Austrian Mining School, who had been sent to P. by Baron Reuter to explore the mineral wealth of the country, reported, in January 1874, the discovery of an important coal-field.

Inhabitants.—The settled population are chiefly Tajiks, the descendants of the ancient Persian race, with an intermixture of foreign blood. To this class belong the agriculturists, merchants, artisans, &c. The Tajiks are Mohammedans of the Shiite sect, with the exception of the remaining Parsees or Guebres (q. v.), numbering 793 in 1868, who are found in Kerman and Fars, and still retain their purity of race and religious faith. The Tajiks have been spoken of as timid, cunning, and servile, but in the cities of Turkestan recently conquered by Russia they make excellent subjects, ready and apt to adopt and appreciate the knowledge and habits of Europe. In the work quoted below, Vauverey speaks of their industry, and their capacity for and love of culture. He says, that which the Japanese are in the east the Tajiks may become in the west of Asia; and it is a settled matter, that they will form the medium for the introduction of the civilization of the West into the interior of Asia. The nomad or pastoral tribes, or *eylats* (*eyl*, a clan), often spelt *illyats*, are of four

distinct races—Turkomans, Kurds, Lâurs, and Arabs. Their organization is very similar to that which formerly subsisted among the Highland clans of Scotland, with the exception that the former are nomad, while the latter inhabited a fixed locality. Each tribe is ruled by its hereditary chief (*wjak*), and under him by the heads of the cadet branches (*tirehs*) of his family. Of the four nomad races, the Turkoman is the most numerous, and forms at the present day the ruling race in Persia. The Kurds are few in number, the greater part of their country and race being under the sway of Turkey. The Arabs are also few in number, and at the present day can hardly be distinguished from the Persians, having adopted both their manners and language. The Lâurs are of nearly pure Persian blood. The nomad races, especially the Turkomans, profess the Sunni creed; they are distinguished from the Tajiks by their courage, manliness, and independence of character; but they are inveterate robbers, and since their entrance into the country in the 10th c., it has been continually distracted by civil wars and revolutions. There is a small population of native Christians—the Nestorians of Urmah and Telmahs. Including those who have joined the Roman Catholic and Protestant churches, their whole number does not exceed 25,000. They are agriculturists, and suffer great wrong and oppression from the chiefs who own the villages in which they live. The Jews number 15,000.

We have no certain information regarding the population of Persia. There can be no doubt that in antiquity, and even during the middle ages, while the irrigation works still fertilized great tracts of country, it supported a great population. A native estimate, referred to by Sir John Malcolm, fixed the modern population at 200 millions. In the 17th century, the French traveler, Chardin, thought 40 millions not too high a figure. Recent travelers, however, reduced these sums to numbers varying from 15 to 8 millions. Much surprise was accordingly expressed when Mr. R. Thompson (see below), who had traveled in every province of P., and collected statistical information, made careful calculation from the taxes collected, &c., and reported that the entire population did not exceed 5 millions, and was probably not over 4 millions. His estimate has since been generally accepted as the most trustworthy we have. He divides the total roughly into one million inhabitants of cities, 1,700,000 nomads, and 1,700,000 peasants and villagers; and the following are his estimates of the population of the chief cities: Tabreez, 110,000; Teheran, 85,000; Meshid, 70,000; Isphahan, 60,000; Yezd, 40,000; Kerman, 30,000; Kermanshah, 30,000; Hamadan, 30,000. There can be no doubt that the population has been long diminishing, a fact attributable to misrule and extortion—neglect of the great irrigation works—and the frequent occurrence of famines in a dry country where cultivation depends on an artificial supply of water.

The insecurity of property has prevented the improvement of land, the extension of trade, and public works of every kind. The roads are utterly neglected. The houses, those of the wealthiest people not excepted, appear contemptible, being generally built of earth or mud, and are grouped, even in the towns, with little attention to uniformity or order. They scarcely ever exceed one story in height, and they are surrounded by high blank walls. The public buildings, such as mosques, colleges, and caravansaries, are of similar appearance to the ordinary houses, and built of the same materials. The interiors, however, of the houses of the rich are sometimes perfect paradises of luxury and elegance; and however much dwellings constructed of mud may offend a European eye, it is questionable whether, with all its disadvantages, mud is not a better building material than wood or stone in a country possessing such a climate as Persia. The miserable look of the towns is, however, greatly improved by the beauty of the gardens which surround them.

Manufactures and Trade.—The trade of P. is comparatively of little importance. The silk is the great staple, and is produced in every province, but chiefly in those of the north. The failure of the crop since 1870 has, however, interfered very seriously with this branch of industry. Cotton and woollen fabrics, shawls, carpets, and felts are largely manufactured for use and export in Khorassan. Trade is carried on by caravans with the interior of Asia and the chief towns of Persia. These caravans exchange the products of P. for muslin, leather, skins, nankeen, china, glass, hardware, gums, dye-stuffs, and spices. The greater part of the commerce of P. centers at Tabreez, to which are conveyed all the products of Eastern P., Turkestan, Cabul, Beloochistan, and India. European goods are brought to Tabreez by Constantinople and Trebizond. While in recent times the great overland routes have been rendered insecure by the unsettled state of Turkestan and Afghanistan, the communication between P. and foreign countries has been increased by the Caspian and the Persian Gulf. On the former sea, in 1873, there was a Russian fleet of schooners and screw steamers. Two or three of these vessels sailed weekly from Astrakhan with merchandise for the Persian coast. There were three passenger steamers, one of which ran weekly to the southern shores of the Caspian, touching at Entzdi, Mashadisar, and

Ashurada. In the Persian Gulf the British India Steam Navigation Company had recently a regular line of fine steamers running fortnightly from Bombay to Bassorah, and touching at Bender-Abbas and Bushire. The exports to India consist chiefly of horses, dried fruit, and drugs; and the imports from that country and Europe, of broadcloths, cotton-goods, jewelry, arms, cutlery, watches, earthen, glass, and metal wares, &c. The whole foreign trade of P. has been estimated roughly at—imports, £2,500,000; exports, £1,500,000. British produce exported to P. in 1875 was £45,728; in 1880, £226,408. Exports from P. to Britain in those years were valued at £44,331 and £81,614. It is doubtful, however, how far the existing commerce of P. will make the construction of railways a profitable speculation. Baron Reuter, under a concession made to him by the Shah, obtained power to construct railways from the Caspian to Teheran, and from Teheran to the Persian Gulf; but there is little expectation of this concession being successful.

Government, Taxation, Education, &c.—The government of P. is a pure despotism, limited only by domestic intrigues, dread of private vengeance, and an occasional insurrection. The last-named is the principal check against unjust government on the part of the monarch, while the former two operate as powerful restraints on his ministers. The monarch, who has the title of 'Shah' and 'Padishah,' possesses absolute authority over the lives and property of his subjects. His deputies, the governors of provinces and districts, possess similar authority over those under them; their actions are, however, liable to revision by the Shah, who may summarily inflict any punishment upon them for real or alleged misgovernment. Oppression of the working and mercantile classes is almost a necessity of such a form of government. The central government consisted until lately of the *Sadri-Azem* or Grand Vizier, with various dependent officials. Now there is a ministry, nominally modelled after the cabinets of European states, of which the head is called President of the Council. He is supported by the ministers of foreign affairs, and of war, of justice, of public worship, and of mines, of commerce, telegraphs, agriculture, industry, and public works, the commander-in-chief, and the master of the ceremonies. The law, which in civil cases is administered by Mollahs (q. v.), in criminal cases by a state court, is founded on the Koran and on tradition. The punishments commonly inflicted are fines, flogging (the *bastinado*), and death, either by decapitation, stabbing, or torture. The Beglerbegs or governors of provinces, who are always chosen from the governing race, the Turkomans, and are generally of the blood-royal, oppress to the utmost the poor Tajiks. They are seldom able, however, to protect their provinces from the ravages of the predatory eylat hordes, who, though nominally subject to the Shah, are governed by their own khans, and are really independent. The revenue is derived—(1.) From a tax on the gross produce of land, 30 per cent. is supposed to be the amount payable to the crown by the landholders.

As a general rule, however, this amount is somewhat exceeded, and 25 per cent. may be taken as the average assessment; (2.) Duties on cattle and flocks—in case of goats, sheep, and cows, 8 per cent. on value of wool and butter yielded; (3.) Customs dues; (4.) Capitation tax of 8*d.* on each male over 18; (5.) Rates levied on incomes of artisans and dealers of 20 per cent., and duties on provisions brought to market. In theory, these are the taxes authorized by the government, but Mr. R. Thomson states that in practice a frightful system of bribery and extortion prevails. The wealthy and influential escape the rapacity of the provincial governors, but as much as possible is taken from the hard-working peasants. He believes that the irregular exactions amount to a sum equal to the legal assessments, and that not a penny of the money so extorted is applied to public purposes. Large sums are extorted from the Jews. The revenue in 1876 was about £1,643,200, of which £1,240,000 were from the direct taxes.

Elementary education is very generally diffused among all classes. There are a large number of colleges where students are instructed in religion, and Persian and Arabian literature. Among the upper classes it is asserted that the Mohammedan religion is rapidly losing its hold, and that unbelief is widely prevalent.

Political Divisions, &c.—From the earliest times down to the present century, P. was divided into seven or eight great divisions; but about the time when it was attempted to introduce European civilization into the country, and discipline into the army, the country was anew divided into 25 provinces—viz., the three Caspian provinces of the Ghilan, Mazanderan, and Astrabad, in the north; Azerbaijan, Ardelan or Persian Kurdistan, Luristan, and Khuzistan, in the west; Fars, Laristan and Kerman with Mogistan, in the south; while the great province of Irak-Ajemi in the center was divided into Khanshah, Kasbin, Teheran, Hamadan, Kûm, and Isphahan; and that of Khorassan in the east, into Yezd, Tabas, Ghayn and Birjun, Turshiz, Meshid, Danghan, Semnum, and the Dasht Beyad, or the Great Salt Desert. There are many interesting ruins of ancient, populous, and celebrated cities in Persia—for example, Persepo-

lis (q. v.), Rhages or Rhé, Shahpur, Istakhar, Tás, Merv, Shushan, Hamadan, &c.; and the monuments and inscriptions found at some of these places form a highly-interesting study. See **BEHISTUN**.

Army.—The standing army, according to the recent army laws, consists of 200,000 men, but the majority of these exist only on paper. The regular army is really composed of about 80,000 infantry and 1000 artillery, while there are about 10,000 irregular cavalry, a few thousand irregular infantry, and the guards. The officers in the Persian army are said to be ignorant and inefficient, but the soldiers are described as being obedient, sober, intelligent, and capable of enduring great fatigue. The irregular cavalry, which forms the bravest portion of the Persian army, is equal to the Cossacks in the Russian army, and much superior to the Turkish sultan's Bashi-Bazouks.

History.—According to the *Shah Nameh* of Firdusi (q. v.), the history of P. begins some thousands of years before the Christian era. Little has yet been done towards extracting the grains of historical truth that may be contained in the mass of fable that constitutes the native Persian annals; although hopes are cherished that by aid of the many inscriptions and monuments that are being daily discovered, light may yet be thrown upon many points. In the meantime, we must rest contented with the accounts derived from Greek writers. The north-western part of Iran, anciently called Media (q. v.), was, at the earliest period known to the Greeks, a part of the Assyrian empire, but the Medes revolted, and (708 B.C.), under Dejoces, established an empire which subdued both that of Assyria and their own kindred tribes of Persis. See **MEDIA**. About 537 B.C., the Persians under **CYRUS** (q. v.)—the Kai-Khshuru of the Persians—(559–529 B.C.) rebelled, subdued their former masters, the Medes (who from this time became amalgamated with them), and established a mighty empire, which included, besides P., as far as the Oxus and Indus, Asia Minor, Syria, Palestine, and Mesopotamia. His son, **CAMBYSES**, a most ferocious and bloodthirsty tyrant (529–522 B.C.), subdued Tyre, Cyprus, and Egypt.

After the brief rule of the usurper **SMERDIS** (522–521 B.C.), **DARIUS I.** (q. v.) surnamed **HYSTASPES**—the Gushtasp of the Persians—(521–485 B.C.), mounted the throne. He was a politic and energetic prince, and succeeded in firmly establishing his dynasty, and adding Thrace and Macedonia to his empire; but his two attempts to subdue Greece were completely foiled, the first by the Thracians, and the second by the Athenians at Marathon (490 B.C.). His son, **XERXES I.** (485–465 B.C.)—the Isfunder of the Persians—renewed the attempt to subdue the Greek states, and though at first successful, the defeats of Salamis and Plataea compelled him to limit himself to a defensive warfare, which exhausted the resources of his kingdom. His son, **ARTAXERXES I.** (465–425 B.C.), surnamed **LONGIMANUS** (the Bahman of the Persians, better known as Ardeshir Dirazdust), was a valiant prince, but he was unable to stay the decadence of P., which had now commenced. He, however, crushed a formidable rebellion in Egypt, though his wars with the Greeks and Ionians were unsuccessful. The empire now became a prey to intestine dissensions, which continued during the reigns of his successors, Xerxes II, Sogdianus, Darius II, Artaxerxes II., and Artaxerxes III. **DARIUS III. CODOMANNUS** (336–329) (the Darab II. of the Persians), the last of the dynasty, was compelled to yield his throne to Alexander (q. v.) the Great, king of Macedon (known as Secunder by the Persians), who reconquered all the former provinces of P., and founded a vast empire, which, at his death in 324 B.C., was divided into four parts, P. along with Syria falling to the share of the Seleucidæ (q. v.), and its old dependency, Egypt, to the Ptolemies (q. v.). The Seleucidæ soon lost Bactria (now Balkh), which became independent under a series of Greek sovereigns; and about 246 B.C., Parthia (q. v.)—now Northern Khorassan—also rebelled under **ARSACES I.** (the Askik of the Persian writers) who founded the dynasty of the Arsacidæ, under whom the greater part of P. was wrested from the Greeks, and maintained against both the Greeks and Romans.

The Greek empire of Bactria, which is said to have included a great part of Hindustan, was overthrown by an influx of nomad tribes from Turkestan, and these invaders having been driven out by the Parthians, Bactria was added to their empire. But the dynasty of the Arsacidæ was brought to an end by a Persian named Ardeshir Babegan, who managed to gain possession of Fars, Kerman, and nearly the whole of Irak, before Arduan, the Parthian king, took the field against him. At last, a great battle was fought (218 A. D.) on the plain of Hormuz, in which the Persians were completely victorious. Babegan was now hailed as Ardeshir, king of P., and 'Shahan Shah,' or king of kings. The history of this dynasty will be found under the head of **SASSANIDÆ**. The Sassanian kings raised P. to a height of power and prosperity such as it never before attained, and more than once perilled the existence of the Eastern Empire. The last king was driven from the throne by the Arabs (636 A.D.), who now began

to extend their dominion in all directions; and from this period may be dated the gradual change of character in the native Persian race, for they have been from this time constantly subject to the domination of alien races. During the reigns of Omar (the first of the Arab rulers of P.), Othman, Ali, and the Omniades (634–750), P. was regarded as an outlying province of the empire, and was ruled by deputy governors; but after the accession of the Abbasside dynasty (750 A.D.), Bagdad became the capital, and Khorassan the favorite province of the early and more energetic rulers of this race, and P. consequently came to be considered as the center and nucleus of the califate. But the rule of the califs soon became merely nominal, and ambitious governors, or other aspiring individuals, established independent principalities in various parts of the country.

Many of these dynasties were transitory, others lasted for centuries, and created extensive and powerful empires. The chief were the **TAHERITES** (820–872), a Turkish dynasty in Khorassan; the **SOFFARIDES** (Persian, 869–903), in Seistan, Fars, Irak, and Mazanderan; the **SAMANI**, in Transoxiana, Khorassan, and Seistan; the **DILEMI** (Persian, 933–1056), in Western Persia; and the **GHIZNEVIDES** (q. v.), in Eastern Persia. These dynasties supplanted each other, and were finally rooted out by the Seljuks (q. v.), whose dominion extended from the Hellespont to Afghanistan. A branch of this dynasty, which ruled in Khwarezm (now Khiva, q. v.) gradually acquired the greater part of Persia, driving out the Ghiznevides and their successors, the **Ghurides** (q. v.); but they, along with the numerous petty dynasties which had established themselves in the south-western provinces, were all swept away by the Mongols (q. v.) under **GENGHIS-KHAN** (q. v.) and his grandson, Hulaku-khan, the latter of whom founded a new dynasty, the **PERSO-MONGOL** (1253–1335). This race becoming effeminate, was supplanted by the **EYKHEHANS** in 1335, but an irruption of the Tartars of Turkestan under **TIMUR** (q. v.), again freed P. from the petty dynasties which misruled it. After the death of Timur's son and successor, Shah Rokh, the Turkomans took possession of the western part of the country, which, however, they rather preyed upon than governed; while the eastern portion was divided and subdivided among Timur's descendants, till, at the close of the 15th c., they were swept away by the **Uzbeks** (q. v.), who joined the whole of Eastern P. to their newly-founded khanate of Khiva. A new dynasty now arose (1500) in Western P., the first prince of which (Ismail, the descendant of a long line of devotees and saints, the objects of the highest reverence throughout Western P.), having become the leader of a number of Turkish tribes who were attached by strong ties of gratitude to his family, overthrew the power of the Turkomans, and seized Azerbaijan, which was the seat of their power. Ismail rapidly subdued the western provinces, and in 1511 took Khorassan and Balkh from the Uzbeks; but in 1514, he had to encounter a much more formidable enemy—to wit, the mighty Selim (q. v.), the Sultan of Turkey, whose zeal for conquest was further inflamed by religious animosity against the Shiites, or 'Sectaries,' as the followers of Ismail were termed.

The Persians were totally defeated in a battle on the frontiers; but Selim reaped no benefit from his victory, and after his retreat, Ismail attacked and subdued Georgia. The Persians dwell with rapture on the character of this monarch, whom they deem not only to be the restorer of P. to a prosperous condition, and the founder of a great dynasty, but the establisher of the faith in which they glory as the national religion. His son Tamasp (1523–1576), a prudent and spirited ruler, repeatedly drove out the predatory Uzbeks from Khorassan, sustained without loss a war with the Turks, and assisted Homayun, the son of Baber, to regain the throne of Delhi. After a considerable period of internal revolution, during which the Turks and Uzbeks attacked the empire without hindrance, Shah Abbas I. the Great (1585–1628), ascended the throne, restored internal tranquillity, and repelled the invasions of the Uzbeks and Turks. In 1605, he inflicted on the Turks such a terrible defeat as kept them quiet during the rest of his reign, and enabled him to recover the whole of Kurdistan, Mosul, and Diarbekir, which had for a long time been separated from P.; and in the east, Candahar was taken from the Great Mogul. Abbas's government was strict, but just and equitable; roads, bridges, caravansaries, and other conveniences for trade, were constructed at immense expense, and the improvement and ornamentation of the towns were not neglected. Ispahan more than doubled its population during his reign. His tolerance was remarkable, considering both the opinions of his ancestors and subjects; for he encouraged the Armenian Christians to settle in the country, well knowing that their peaceable and industrious habits would help to advance the prosperity of his kingdom. His successors, Shah Sufi (1628–1641), Shah Abbas II. (1641–1666), and Shah Soliman (1666–1694), were undistinguished by any remarkable talents, but the former two were sensible and judicious rulers, and advanced the prosperity of their subjects.

During the reign of Sultan Hussein (1694–1722), a weak and bigoted fool, priests and slaves were elevated to the most impor-

tant and responsible offices of the empire, and all who rejected the tenets of the Shiites were persecuted. The consequence was a general discontent, of which the Afghans (q. v.) took advantage by declaring their independence, and seizing Candahar (1709). Their able leader, Meer Vais, died in 1715; but his successors were worthy of him, and one of them, Mahmud, invaded P. (1722), defeated Hussein's armies, and besieged the king in Ispahan, till the inhabitants were reduced to the extremity of distress. Hussein then abdicated the throne in favor of his conqueror, who, on his accession, immediately devoted his energies to alleviate the distresses and gain the confidence of his new subjects, in both of which objects he thoroughly succeeded. Becoming insane, he was deposed in 1725 by his brother Ashraf (1725—1729); but the atrocious tyranny of the latter was speedily put an end to by the celebrated Nadir Shah (q. v.), who first raised Tamasp (1729—1732) and his son, Abbas II. (1732—1736), of the Saffavean race, to the throne, and then, on some frivolous pretext, deposed him, and seized the sceptre (1736—1747). But on his death, anarchy again returned; the country was horribly devastated by the rival claimants for the throne; Afghanistan (q. v.) and Beloochistan (q. v.) finally separated from P., and the country was split up into a number of small independent states till 1755, when a Kurd, named Kerim Khan (1755—1779), abolished this state of affairs, re-established peace and unity in Western Persia, and by his wisdom, justice, and war-like talents, acquired the esteem of his subjects, and the respect of neighboring states. After the usual contests for the succession, accompanied with the usual barbarities and devastations, Kerim was succeeded in 1784 by Ali-Murad, Jaafar, and Luft-Ali, during whose reigns Mazanderan became independent under Aga-Mohammed, a Turkoman eunuch of the Kajar race, who repeatedly defeated the royal armies, and ended by depriving Luft-Ali of his crown (1795).

The great eunuch-king (as he is frequently called), who founded the present dynasty, on his accession announced his intention of restoring the kingdom as it had been established by Kerim Khan, and accordingly invaded Khorassan and Georgia, subduing the former country almost without effort. The Georgians besought the aid of Russia; but the Persian monarch, with terrible promptitude, poured his army like a torrent into the country, and devastated it with fire and sword; his conquest was, however, hardly completed, when he was assassinated, May 14, 1797. His nephew, Futeh-Ali (1797—1834), after numerous conflicts, fully established his authority, and completely subdued the rebellious tribes in Khorassan, but the great commotions in Western Europe produced for him bitter fruits. He was dragged into a war with Russia soon after his accession, and by a treaty, concluded in 1797, surrendered to that power Derbend and several districts on the Kur. In 1802, Georgia was declared to be a Russian province. War with Russia was recommenced by P., at the instigation of France; and, after two years of conflicts disastrous to the Persians, the treaty of Gushistan (October 12, 1813) gave to Russia all the Persian possessions to the north of Armenia, and the right of navigation in the Caspian Sea. In 1826, a third war, equally unfortunate for P., was commenced with the same power, and cost P. the remainder of its possessions in Armenia, with Erivan, and a sum of 18,000,000 rubles for the expenses of the war. The severity exercised in procuring this sum by taxation, so exasperated the people, that they rose in insurrection (October 12, 1829), and murdered the Russian ambassador, his wife, and almost all who belonged to, or were connected with the Russian legation. The most humiliating concessions to Russia, and the punishment by mutilation of 1500 of the rioters, alone averted war. The death of the crown-prince, Abbas-Mirza (q. v.), in 1833, seemed to give the final blow to the declining fortunes of P., for he was the only man who seriously attempted to raise his country from the state of abasement into which it had fallen.

By the assistance of Russia and Britain, Mohammed Shah (1834—1848), the son of Abbas-Mirza, obtained the crown. He conceived ambitious ideas of annexation. In the days of Nadir Shah, and indeed at many other periods, the Persian frontier had extended over a great part of the Afghan, Belooch, and Khivan boundary. Mohammed resolved to demand reacknowledgment of sovereignty from his alleged vassals in these countries, but an attempt he made to reannex Herat, 'the key to India,' was resisted by England. The war was terminated in 1838, by the landing of a small sepoy force on the shores of the Persian Gulf. Nazir-uddin succeeded to the throne on his father's death in 1848; and the new government announced energetic reforms, but failed as completely as those which had preceded it in carrying them out. Following his father's example, the new Shah resolved to reassert his claims in Afghanistan and Beloochistan. The ruler of Herat having recognized the claims of Persia, the English Government remonstrated with the Shah, and he was compelled to sign an engagement on the 25th January 1853, by which he became bound not to interfere farther with the internal affairs of Herat. In October 1856, however, on the pretext that Dost Mohammed the Ameer of Cabul, was about to invade Herat, the Persians again

took the city. Having thus violated the terms of the treaty with Britain, war was declared against them, and a British army was landed on the coast of the gulf, which, under Generals Outram and Havelock, repeatedly defeated the Persians, and compelled them to restore Herat (July 1857). Since this time the Persians have not interfered with the 'key to India,' to which so much importance has been attached by England, but they have been engaged in a long series of disputes with regard to their frontier north and south of it. After the war of 1857, their encroachments became systematic. In 1868, they occupied Seistan, a province claimed by the Afghans, and extended their jurisdiction over the western third of the country appearing on our maps as Beloochistan. To put an end to the incessant strife to which these pretensions gave rise, the Persians at length agreed with the Ameer of Afghanistan and the Khan of Kelat to refer the questions in dispute to an English commissioner.

General Sir Frederick Goldsmid accordingly visited the eastern frontier of P., and in 1872 delivered his award. It entirely alters the form familiar to us as that of south-eastern P. It carries the Belooch frontier back from 58° to 63° east longitude, so as to include in P. the inland town of Jalk, and Guadar on the Indian Ocean. All the western shores of the Lake of Zirreh, and a large triangular tract to the east of it, watered by the Helmund, are also annexed to Persia. The north-eastern frontier has not yet been settled. In 1870 the Russians admitted that the jurisdiction of P. should extend over the whole basin of the Atrak. It has been found, however, that between it and the Khivan desert there lies the fertile ridge of the Daman-i-koh and the water-course of the Tejend Rud, along which lies a route from the Caspian to Merv and Herat. Merv, the center of the oasis of Margiana, and which is almost as much a key to India as Herat itself, has been claimed both by Khiva and P., and now that the Russians have become masters of the former country, the settlement of the frontier of P. in this direction has become the most urgent question of Persian politics, connected closely as it is with the determination of the Anglo-Russian frontier in Central Asia. In 1873 the Shah visited Europe. By the treaty of Berlin in 1878, the town and territory of Khotour, on the Turco-Persian frontier, was ceded to P. by Turkey.

G. Watson (Lond., 1878); *History of Persia*, by G. Clements R. Markham (1874); *Central Asia and the Anglo-Russian Frontier Question*, by A. Vambery (1874); *Through Persia*, by Arnold (1876); *Persia*, by Goldsmid (1880); and F. Martin's *Statesman's Year-Book*. Also German works on Persia by Spiegel (1863), Brugsch (1864), Polak (1865).

PE'RSIAN ARCHITECTURE. The architecture of Persia is of considerable interest, both on its own account, and as supplementary to and explanatory of that of Assyria, which, together with the similar edifices in Egypt, is the earliest architecture of which we have any knowledge. The buildings of Persia and Assyria closely resemble one another, and, owing to the mode and the materials in which they were constructed, their remains serve to illustrate and complete each other's history. In Assyria, where no solid building materials exist, the walls are composed of masses of sun-dried brickwork, lined on the inside, to a certain height from the floor, with large sculptured slabs of alabaster. These have been preserved to us by the falling in of the heavy earthen roofs, with which, as the later Persian buildings explain to us, the Assyrian palaces were covered. The explorations of Layard and Botta, and the specimens brought home by the former, and now in the British Museum, have made these sculptures familiar to us. The subjects usually are large bulls with human or lions' heads; priests with human bodies, and eagles' or lions' heads, performing religious services before the 'sacred tree.' The Assyrian remains are all of palace-temples, buildings somewhat resembling the Egyptian temples (which were also palaces); and many of the sculptures represent the exploits of the king in war and in peace. The palaces are always raised on lofty artificial mounds, and approached by magnificent flights of steps.

The buildings of Assyria extend over a very long period, the oldest at Nimroud being from 1300 to 800 B.C., and the more recent at Khorsabad and Koyunjik from 800 to 600 B.C. To these succeeded Babylon in the reign of Nebuchadnezzar, and the Birs Nimroud; but these are mere masses of decomposed brickwork, without any sculptures of harder material.

After Babylon came Pasargadæ—where the splendid palaces of Cyrus and Cambyses still exist in ruins—and Persepolis, the capital of Darius and Xerxes (560—523 B.C.), and some remains are still to be found at Susa, Ecbatana, and Teheran. At Persepolis, we find the very parts preserved which at Nimroud and Khorsabad are wanting; for here there is abundance of stone, and the

pillars, walls, doorways, &c. (which, in the early examples, were no doubt of wood, and have decayed), being of stone, are still preserved. This has enabled Mr. Fergusson to 'restore' these buildings, and to produce most interesting designs, showing not only how the palaces of Persia were constructed and lighted, but from them to suggest how the arrangements of all the ancient architecture of Egypt and Syria must have been designed.

The halls at Persepolis were square in plan, having an equal number of pillars in each direction for the support of the roof, which was flat. In the center, a portion was left open for the admission of light, and sheltered by another roof raised upon pillars. The accompanying section (fig. 1) of the Great Hall of

Fig. 1.—Section of Hall of Xerxes at Persepolis.

Xerxes (from Fergusson's *Handbook of Architecture*) will explain this arrangement. This hall is the most splendid building whose remains exist in this part of the world. The remains of the 72 columns with which it was adorned are still extant (fig. 2). The

Fig. 2.—Plan of Great Hall of Xerxes at Persepolis.

hall had 36 columns, six on each side, and on three sides had an external portico, each with two rows of six columns. These columns had capitals, composed of bulls' heads and shoulders (fig. 3), between which the beams of the roof rested; while others were ornamented with scrolls like the Ionic order (fig. 4). The bases

Details of Persian Architecture.

Fig. 4.

also are suggestive of the origin of that Greek style. This hall was 350 feet by 300, and covered more ground than any similar

buildings of antiquity, or any medieval cathedral except that of Milan.

The palaces of Persepolis stand on lofty platforms, built with walls of Cyclopean masonry, and approached by magnificent flights of stairs, adorned, like the palaces, with sculptures somewhat similar to those of Assyria. The interiors were ornamented with paintings. The use of the arch was known in Assyria, as has been shown by the subterranean arched conduits discovered by Layard, and the gates of Khorsabad discovered by M. Place. The arches of the latter spring from the backs of sculptured bulls, and are beautifully ornamented with enamelled bricks.

PERSIAN GULF, an arm of the Indian Ocean which penetrates between Arabia and Persia to the extent of 650 English miles in a general north-westerly direction. Its breadth varies from 55 miles at the mouth to 250 miles, and the area is estimated at 117,300 square miles, from which about 1930 square miles must be subtracted for the islands, which are scattered over the western half, or lie close inshore along the eastern side. The chief of these islands are Ormuz (q. v.), at the mouth; Kishm, 810 square miles in extent; and the Bahrein Islands (q. v.), chief of which is Samak. The Great Pearl Bank stretches along the western side from Ras Hassan to nearly half-way up the gulf. The coast is mostly formed of calcareous rocks. On the Arabian side, it is low and sandy, occasionally broken by mountains and cliffs; while, on the Persian side, it is higher and abrupt, with deep water close inshore, owing to the mountain-ranges of Fars and Laristan running close to the water's edge. The islands are partly of limestone and partly of ironstone, and are generally destitute of springs, barren, desolate, and presenting numerous traces of volcanic eruptions. With the exception of the Shat-el-Arab (q. v.), the P. G. receives only insignificant streams. Its eastern side presents abundance of good anchorage, either in the numerous bays or in the lee of islands. The greater portion of its shores now belongs to the Inaam of Muscat. The coasts of the gulf have been explored by successive British expeditions, the last of which, in 1821—1825, made a complete trigonometric survey of the Arabian shore. The order of the periodic currents in this gulf is precisely the reverse of that of the Red Sea (q. v.) currents, as they ascend from May to October, and descend from October to May.

Oriental geographers give to this gulf the name of the 'Green Sea,' from a remarkable strip of water of a green color, which lies along the Arabian coast. It is strange that from the time of Nearchus, the admiral of Alexander the Great, who was the first to make the P. G. known to Europeans, the Persians have never ruled supreme over its surface.

PERSIAN LANGUAGE AND LITERATURE. The ancient and modern idioms of Persia, which are in general designated as Iranian or West Aryan, belong to the great class of the Indo-Germanic languages; but the term Persian itself applies more particularly to the language as it is now spoken, with a few exceptions, throughout Persia, and in a few other places, formerly under Persian dominion, like Bokhara, &c. The more important and better-known of the ancient idioms are (1) the *Zend* (the East Indian or Bactrian languages, in two dialects—the *Gāthā* idiom, and the 'ancient' or 'classical *Zend*'), which died out in the 3d c. B. C.—one of the most highly-developed idioms, rich in inflections, in the verbs as well as in the nouns, and in the former almost completely agreeing with Vedic Sanscrit; yet such as we find it in the small remains which have survived, it is no longer in the full vigor of life, but almost decaying, and grammatically somewhat neglected; it is in fact held by a great authority on the subject (Haug), that the grammar was never fixed in any way by rules. To increase the difficulty still more, the texts—the Zoroastrian books—never seem to have been copied with proper care, or by men who had any correct knowledge of the language; so that the critical restoration of the literary remains is matter of extreme difficulty, and *Zend* studies in general may be said to be in their infancy yet. Geographically, this idiom may be placed in Northern Persia. Its alphabet is of Semitic origin, and the writing goes from right to left (see *ZEND*, *ZEND-AVESTA*).

(2) *Ancient Persian*, the chief remnants of which are found in the cuneiform inscriptions of the time of the Achaemenides, discovered in the ruins of Persepolis, on the rock of Behistun, and some other places of Persia (see *CUNEIFORM*). Some relics, chiefly consisting of proper names for gods and men, and terms for vessels and garments, have survived in the writings of the classical period, and in the Bible, chiefly in Daniel. This idiom is much nearer to *Zend* and Sanscrit than to modern Persian. It has still the structure of an ancient organic Indo-Germanic language, with the distinct peculiarities of an Iranian tongue. (3) *Pehlevi* (q. v.) (West Iranian, Median, and Persian), in use during the period of the Sassanians (3d to 7th c. A.D.), an idiom largely mixed with Semitic words, and poorer in inflections and terminations than *Zend*. Its remnants consist of a certain number of books relating to the Zoroastrian religion, of coins and inscrip-

tions; and the language is not quite the same in all cases—according to the larger or smaller infusion of foreign words. The non-Iranian element is known as Huzvaresh, and is simply Chaldee; while the Iranian element is but little different from modern Persian. There are three distinct idioms to be distinguished in Pehlevi, and the writing varies accordingly, yet it is not certain whether the difference arises from their belonging to different districts or periods. When, however, Pehlevi ceased to be a living language, and the restoration of the pure Iranian had begun, people, not daring to change the writings, chiefly of a sacred nature, as they had descended to them from the Sassanian times, began to substitute, in reading, the Persian equivalents to the Huzvaresh words. At last a new form of commentaries to the sacred writings sprang up, in which more distinct and clear Zend characters were used, where each sign has but one phonetical value, and where all the foreign Huzvaresh words were replaced by pure Persian ones; and this new form was called (4) *Pāzend*.

The transition from the ancient to the modern Persian is formed by the *Parsee*, or, as the Arabs call it, *Farsi*, in use from 700 to 1100 A.D., once the language purely of the south-western provinces, and distinguished chiefly by a peculiarity of style, rigid exclusion of Semitic words, and certain now obsolete forms and words retained in liturgic formulas. It is the Persian once written by the Parsees or fire-worshippers, and is in other respects very similar to the present or *modern Persian*, the language of Jāmi, Nizāmi, and Hāfiz—from 1100 to the present time—with its numerous dialects. The purest dialect is said to be that spoken in Shiraz and Ispahan and their neighborhood. In general, the language is pronounced by universal consent to be the richest and most elegant of those spoken in modern Asia. It is the most sonorous and muscular, while at the same time it is the most elegant and most flexible of idioms; and it is not to be wondered at, that, throughout the Moslem and Hindu realm, it should have become the court language, and that of the educated world in general; holding a position somewhat similar to that which the French language held up to within a recent period in Europe. Its chief characteristic, however, is the enormous intermixture of Arabic words, which, indeed, almost make up half its vocabulary. Respecting its analytical and grammatical structure, it exhibits traces only of that of the ancient dialects of Zend and Achæmænian, of which it is a direct descendant. The elaborate system of forms and inflections characteristic of those dialects has been utterly abandoned for combinations of auxiliary words, which form independent connective links, and which impart fulness and an incredible ease to speech and composition, but which at the same time, correspond as little to the classical notion of inflection.

The grammar of the Persian language has been called 'regular'; but the fact is, that there is hardly any grammar worth mentioning—at all events, no grammar the rules of which could not be mastered in the briefest possible period. To begin with: there is no gender distinguished in declension; the plural is always formed in the same manner, the only distinction consists in animate beings receiving the affix *ān*, while the inanimate are terminated in *hā*; further, that instead of the inflection in the different cases found in the ancient languages, either a *mar* (hitherto unexplained) is prefixed, or a *rā* (*rāh* = way, by reason of, Pehlevi, *Parsi*) is affixed. Between the genitive and the word which governs it, also between a noun and its following adjective, an *i* is inserted. This is the whole declension, not only of the noun, but also of the adjective and pronoun. The comparative is formed, as in the mother-tongue, by the addition of *ter*; the superlative adds *terin*, which is New-Persian exclusively. Not even the pronouns have a gender of their own; the distinction between masculine and feminine must be expressed by a special word, denoting male or female. There is no article, either definite or indefinite. Singularity of a noun is expressed by an appended *ē*, a remnant of *āeva*, one. The flexion of the verb is equally simple. There is a set of personal terminations for all tenses:—*am*, *i*, *ad* or *ast*; *ēm*, *ēd*, *nā*; the infinitive ends in *tan* or *dan*, the past participle in *tah* or *dah*. The aorist is formed by adding to the root the terminations *am*, *i*, *ad*; *em*, *ed*, and; the preterite by dropping the *n* of the infinitive, and substituting the usual terminations. The prefix *mi* or *hami* (Parsi and Huzvaresh = always) transforms the preterite into the imperfect; while the prefix *bi* or *bih* (the present of the verb 'to will') alters the aorist into the simple future. The other tenses are compounds of the past participle and auxiliary verbs, as in the Teutonic and other modern tongues. The passive is formed by the various tenses of the verb *shudan*, 'to be, to go, to beware,' being placed after the past participle.

As to syntax, there is none, or, at all events, none which would not come almost instinctively to any student acquainted with the general laws of speech and composition. As the time of its greatest brilliancy may be designated that in which Firdusi wrote, when Arabic words had not swamped it to the vast degree in which it is now found, and were still, as far as they had crept in, amen-

able to whatever rules the Persian grammar imposed upon the words of its own language.

In the history of the Persian writing, three epochs are to be distinguished. First, we have the Cuneiform (q. v.), by the side of which there seems, however, to have been in use a kind of Semitic alphabet for common purposes. This, in the second period, appears to have split into several alphabets, all related to each other, and pointing to a common Syriac origin (such as the different kinds of Pehlevi characters and the Zend alphabet) cleverly adapted to the use of a non-Semitic language. In the third period, we find the Arabic alphabet enlarged for Persian use by an addition of diacritical points and signs for such sounds as are not to be found in Arabic (*p*, *ch*, *zh*, *g*). The characters are written in a somewhat more pending manner (Talikh) in Persian, and the writing is thus slightly different from the usual Arabic Neskhi.

The much-spoken-of close connection between German and Persian—both of Indo-Germanic kin—is neither more nor less than a popular fallacy, caused by a misunderstood dictum of Leibnitz: 'Integri versus Persice scribi possunt quos Germanus intelligat.' which was enthusiastically taken up and 'proved' by Adelung, Hammer-Purgstall, and others, and which has even led to the assumption, that the Germans came direct from Persia, or that the Goths once were mixed with the Persians. We only mention it as a philological absurdity of bygone days.

Of the Literature of Persians before the Mohammedan conquest, we shall not speak here, but refer to the special articles ZEND, PEHLEVI, PARSEES, &c. The literary period now under consideration is distinguishable by the above-mentioned infusion of Arabic words into the Persian language, imported together with the Koran and its teachings. The writers are, in fact, one and all, Mohammedans. With the fanaticism peculiar to conquering religions, more particularly to Islam, all the representatives of old Persian literature and science, men and matter, were ruthlessly persecuted by Omar's general, Saad Ibn Abi Wakkas. The consequence was, that for the first two or three centuries after the conquest, all was silence. The scholars and priests who would not bow to Allah and his Prophet and to the new order of things, and who had found means to emigrate, took with them what had not been destroyed of the written monuments of their ancient culture; while those that remained at home were forced to abandon their wonted studies. Yet by slow degrees, as is invariably the case under such circumstances, the conquered race transformed the culture of the conquerors to such a degree, that native influence soon became paramount in Persia, even in the matter of theology—the supreme science. It is readily granted by later Mohammedan writers, that it was out of the body of the Persians exclusively that sprang the foremost, if not all, the greatest scholars and authors on religious as well as grammatical subjects, historians and poets, philosophers and men of science; and the only concession they made consisted in their use of the newly-imported Arabic tongue. A further step was taken when, after the Islam sway had ceased, the Persians, under upstart native dynasties, returned also to the ancient language of their fathers during the first centuries of Mohammedanism.

The revived national feeling, which must have been stirring for a long time previously among the masses, then suddenly burst forth in prose and in verse, from the lips of a thousand singers and writers. The literary life of Persia, the commencement of which is thus to be placed in the 9th c. A.D., continued to flourish with unabated healthy vigor for five centuries, and produced a host of writers in every branch of science and belles-lettres, of whom we can only here give the most rapid of surveys, referring for the most important names to the special articles throughout this work. Beginning with poetry, we hear, under the rule of the third of the Samanides, Nasr (about 952), of Abul Hasan Rudegi, the blind, who rose by the king's favor to such an eminence that he had 200 slaves to wait upon him. But little has remained of his 1,800,000 distichs, and of his metrical translation of Bidpai's Fables. About 1000 A.D., we hear of Kabus, the Dilettante prince, as the author of *The Perfection of Rhetoric*, and Poems. In the time of the Gasnevides, chiefly under Mahmud, who surrounded himself with no less than 400 court-poets, we find those stars of Persian song, Ansari (1039), the author of *Wamik and Asra*, and 30,000 other distichs and Kassidahs in honor and praise of the king; further, Ferruchi, who, besides his own poems, also wrote the first work on the laws of the Persian metrical art; and above all Firdusi (q. v.), that greatest epic poet, the author of the *Shah-Nameh*, or Book of Kings; who led one of the most brilliant and romantic lives that ever fell to the lot of genius, and ended it forgotten and in misery. With him, but darkened by his brightness, flourished Esedi, his countryman, from Tus. Among the poets who flourished under the Atabek dynasty, we find that most brilliant Persian panegyrist, Anhad Addin Enweri, who, with his praise, well knew how to handle satire. The best of the older mystic poets of that period is Senayi, author of 30,000 distichs,

who for his poem *Hadikat* was nominated official singer of the Sufis. Nizami (about 1200) is founder of the romantic epos; the greater part of his *Chamsah*, or collection of five romantic poems (*Chosru and Shirin*, *Mejnan and Leila*, &c.), being almost as well known in Europe as it is in the East; and to whom Kislarslan the king presented for one of these poems no less than fourteen estates.

His grave at Gendsheh is still visited by many a pious pilgrim. And here we must mention that the branch of eastern theosophical literature pre-eminently cultivated in Persia is the mystic (Sufistic) poetry, which, under Anacreontic allegories, in glowing songs of wine and love, represented the mystery of divine love and of the union of the soul with God (see *SUFISM*). In this province we find chiefly eminent poets like Senâji (about beginning of 13th c.), and Ferid Eddin Attar (born 1216), the renowned author of *Pend Nameh* (Book of Counsel), a work containing the biographies of saints up to his day. His principal strength, however, lay in his mystic poems; and such is the depth and hidden meaning of his rhymes, that for centuries after him, the whole Moslem world has busied itself with commentaries and conjectures on the meaning of a great part of his sacred poetry. He died about 1330, more than a hundred years old, as a martyr. Greater still, in this peculiar field, is Djâlal Eddin Rumi, born at Balkh (died 1266), the founder of a still existing most popular order of dervishes (Mewlewî). His poem on *Contemplative Life* has made him the oracle of oriental mysticism up to this day. He wrote also a great number of lyrical poems, which form, as far as they have been collected for this special purpose, a breviary for the faithful Sufi. Anhâdî of Meraga (died 1297) also deserves mention.

The 13th c. cannot better be closed than with Sheikh Muslih Eddin Sadi of Shiraz (died 1291), the first and unrivalled Persian didactic poet. His *Bostan* and *Gulistan* (Rose and Fruit-Garden) are not only of Eastern but also of European celebrity, and most deservedly, embodying as they do all the mature wisdom, the grace and happiness of composition of a true poet, ripe in years as in experience. At the beginning of the 14th c., we meet several meritorious imitators of Sadi in didactic poetry.

But far above all these, as above all other Persian lyrical and erotic poets, shines Hâfiz (q. v.), the 'Sugar-lip,' who sang of wine and love, and nightingales and flowers, and who so offended mock-piety, that it even would have tried to refuse him a proper burial, had not the oracle of the Koran interposed. After him, the full glory of Persian poetry begins to wane. Among those that came after him, stands highest Djâmi, who died in 1492, a poet of most varied genius, second only in every one of the manifold branches to its chief master—in panegyric to Enveri, in didactic to Sâdi, in romance to Nizami, in mysticism to Jelâled-din in lyric to Sâdi; and he, with these and Firdusi, form the brightest representatives of Persian poetry. Most brilliant, however, is Djâmi as a romantic poet. Of prose works, we have by him a history of Sufis, and an exceedingly valuable collection of epistolary models. Before concluding this branch of literature, we must take notice of the dramatic poetry of the Persians, which is not without merit, but of small extent, and to be compared principally with the ancient French mysteries.

The numerous tales, stories, novels, anecdotes, anthologies, and all the miscellaneous entertaining literature in which Persia abounds—and of which the best known, perhaps, are the adaptation of Bidpai's Fables; *Avvari Suheili*, by Hussein Vais Kashtî; the *Tutinameh*, or Book of Parrots, a collection of fairy tales, by Nechshebi; the *Behari-Danish*, by Inajeth Allah, &c.—form a fit transition from poetry to prose, for little more is to be said of Persian poetry after the 15th century. Modern imitations of ancient classical works, such as the New Book of Kings, the *Shahinshah-Nameh*, which treats of modern Persian history; the *George Nameh*, which sings the English conquests in India, &c., are hardly worth pointing out in so brief a summary as ours.

Of native writers on the poets, are to be named Dewlet Shah (who describes the poets from the 10th to the 15th centuries), Sam Mirsa (the poets of the 16th), and Luft Ali Beg (the poets of modern time). In prose, it is chiefly history which deserves our attention. Able rivals of the great Arabic historiographers sprang up at an early period. For the mythical times, or those of which no knowledge, save through a medium of half-legend, has reached later generations, Firdusi's gigantic epos remains the only source. But after the chroniclers we find Fâdhî Allah Reshid Eddin, the vizier of Ghazan, born 1247 at Hamadan, who was executed in 1320. He wrote the *Collector of Histories*, in three volumes, to which he afterwards added a fourth geographical volume: a summary of the history of all Mohammedan countries and times, containing besides a complete history of sects. Worthily and contemporaneous rivals are Fachr Eddin Mohammed Bina Kiti, author of a universal history; and Khodja Abdallah Wassaf, the panegyrist, the model of grand and rhetorical style. His most successful imitator in the 14th c. is Abdel Ressaq; and in the 15th, Sherif

Eddin Ali Yezdi, who wrote the history of Timûr. Up to that period, pomposity of diction was considered the principal beauty, if not the chief merit, of a classical Persian history. From the 15th c. downwards, a healthy reaction set in, and simplicity and the striving after the real representation of facts, became the predominant fashion. As the *facile princeps* among these modern historians is to be mentioned Mirkhond, whose Universal History (*Rassat Essafa*) comprises the period from creation to the reign of Sultan Hasan Beikara, in seven books. After him are to be mentioned his son Khondemir, Gaffari, Moslih Eddin Mohammed Lari, and Abu Tahir of Tortosa in Spain, who wrote the *Derab Nameh*, a biographical work on the Persian and Macedonian kings, and the ancient Greek physicians and philosophers.

Among Indian historians—and they form a most important class—who wrote in Persian, we have Mohammed Kasim Ferishtah (1640), who wrote the ancient history of India up to the European conquest; Mohammed Hashim, Abul Fadel Mobarrek (*Akbar Nameh*); further, Abdel Ressaq (*History of the Padishahs*), Mirza Mehdi, Cholam Hussein Khan, and others. One of the most recent works of this description is the *Measiri Sultaniye*, which contains the history of the present dynasty of Persia, and which was published in Teheran, 1825, and translated by Bridges (Lond. 1833).

Biographies, legends, histories of martyrs, and the like are legion. Most of the biographies of the Prophet, however, are taken from the Arabic.

Little is to be said of Persian productions on special branches of exact science. There are a few works on geography—more generally treated together with history—such as those of Mostafi, Ahmin Ahmed Rasi, Berdshendi, &c. In theology, little beyond translations of the Koran, and a few commentaries on single chapters, and of some portions of the Traditions (*Sunnah*), has been produced—the Arabic works being completely sufficient, in religious matters, for all Mohammedans. For the history of early Persian religion are of importance the *Ulemai Islam* and the *Dabistan*, a description of all the creeds of the East. Jurisprudence has likewise to show little that is original, and not mere translation, partial commentary, or adaptation in Persian. The *Heddashah*, the *Inadshah*, the *Futawa Alemgiri*, are the most important legal works to be mentioned here. A great deal has been done in the field of medicine, surgery, pharmacy, physical sciences, by Persians; but nearly all their chief works being written in Arabic, they do not concern us here. Mathematics, astronomy, and philosophy, have received due attention; rhetoric, the art of letter-writing, metrical and poetical arts, have likewise been cultivated with great assiduity, but few standard works are to be enumerated.

Grammar and lexicography found their principal devotees in India; and of dictionaries, the *Perhenji-Shiuri*, *Burhani Katru*, and principally the *Haft Kulzum* (the Seven Seas), by the Sultan of Oude, deserve attention. Translations from Greek, Indian, Arabic, Turkish, and other works into Persian, exist in great abundance, and some of them have paved the way to the knowledge of the original sources in Europe.—Chief authorities and writers on the subject of Persian Language and Literature, are Meninsky, Richardson, Lumsden, Forbes, Ibrahim De Lacy, Hammer-Purgstall, Briggs, Jones, Duperron, Stewart, Quatremere, Wilken, Defrémery, Vullers, Iken, Kosegarten, Ouseley, Chodzko, Bland, Sprenger, Graft, Brockhaus, Dorn.

PERSIAN POWDER, a preparation of the flowers of the composite plant *Pyrethrum carneum* or *roseum*, which are dried and pulverized. This powder has wonderful efficacy in destroying noxious insects, and is extensively used for that purpose in Russia, Persia, and Turkey. It has lately been introduced into France and Britain, and promises to be of great use, not only in ridding houses of their insect pests, but in aiding the horticulturist in protecting his plants. The plant is a native of the Caucasus, where the flowers are gathered wild, and sent to be manufactured chiefly at Tiflis. It might readily be cultivated in this country, where its value for destroying moths alone would render it a profitable crop. Its habit is very similar to that of camomile.

PERSIGNY, JEAN GILBERT VICTOR, DUC DE, whose proper name was FIALIN, a noted adherent of the Emperor Napoleon III., was born at Saint-Germain-Lespinasse, in the department of Loire, 11th January 1808, entered the *École de Cavalerie* at Saumur in 1826, and obtained an appointment to the 4th regiment of hussars in 1828. At this period, Fialin was royalist in his politics; but he soon changed to a liberal, and took an active part in the July revolution. Insubordination, however, led to his final expulsion from the army in 1833. After a brief trial of Saint-Simonianism, Fialin was converted to the Bonapartist cause, dropped the name of Fialin, and took up that of P. (from an 'hereditary estate'), with the title of Vicomte. Introduced to Louis Napoleon by the ex-king Joseph, he at once formed the most intimate relations with the Prince, and commenced a career of Bonapartist propagandism throughout France and Germany,

in which he displayed extraordinary energy, pertinacity, and fertility of resource. He had the chief hand in the affair of Strasbourg, and subsequently apologized of its humiliating failure in a pamphlet entitled *Relation de l'Entreprise du Prince Napoleon Louis* (Lond. 1837), in which he throws the blame of the disaster on 'Fate.' He also took part in the descent on Boulogne, where, like his master, he had the misfortune to be captured, and was condemned to twenty years' imprisonment. His confinement, however, after a short time, became almost nominal, and he beguiled his leisure by literary study, a partial result of which may be seen in his voluminous memoir, addressed to the Institute, on the *Utilité des Pyramides d'Egypte* (1844). On the breaking out of the revolution in 1848, P. hurried to Paris, and set himself, with all his accustomed vigor and swiftness, to organize the Bonapartists. It is hardly too much to affirm that it was this dexterous agitator who made his master President of the Republic. He was then appointed aide-de-camp to the President and Major-general of the Parisian National Guard—perhaps with a view to future contingencies. In 1849, he was chosen a member of the Legislative Assembly, and immediately signaled himself in parliament, as he had previously done out of doors, by his absolute devotion to the policy of the Elysées. He was sent to Berlin as ambassador at the close of the same year, and afterwards held other high diplomatic offices; took a prominent part in the *coup d'état* of December 1851; and, in January 1852, succeeded M. de Morny as Minister of the Interior.

On the 27th of May following, he married a grand-daughter of Marshal Ney, when the president conferred on him the title of *Comte*, and presented him with 500,000 francs. In 1855, he became ambassador at the English court, which office he held till 1858, and again during 1859–1860, leaving on both occasions the most favorable impression on English statesmen, by his talent and diplomatic tact. In the latter year, he was recalled, to assume the office of Minister of the Interior. He laid down the portfolio of this office in June 1863, when the elections of Paris and other large towns showed dissatisfaction with his policy. In September of the same year he was created duke. Thereafter he proved himself in the Senate a zealous Bonapartist till the overthrow of the empire. He did not long survive it, having died in 1872.

PERSIMON. See DATE PLUM.

PERSIUS (Aulus Persius Flaccus), one of the most famous Roman satirists, was born at Volaterræ in Etruria, 34 A.D. He was of a distinguished equestrian family, was educated under the care of the Stoic, Cornutus, lived on terms of intimacy with the most distinguished personages of his time in Rome, among whom were Lucan and Seneca, and died 24th November 62 A.D., in the 28th year of his age. The principal authority for the life of P. is an abridgment of a 'commentary' by one Probus Valerius, which presents the character of the satirist in a most amiable light. Modest and gentle in his manners, virtuous and pure in his whole conduct and relations, he stands out conspicuously from the mass of corrupt and profligate persons who formed the Roman 'society' of his age; and vindicated for himself the right to be severe, by leading a blameless and exemplary life. His six Satires are very commonly printed with those of Juvenal. They were immensely admired in P.'s own day, and long after, all down through the middle ages. The Church Fathers, Augustine, Lactantius, and Jerome, were particularly fond of him—the latter, it is said, has quite saturated his style with the expressions of the heathen satirist; but the estimate which modern critics have formed of his writings, in a literary point of view, is not quite so high. They are remarkable for the sternness with which they censure the corruption of morals then prevalent at Rome, contrasting it with the old Roman austerity and with the Stoic ideal of virtue.

The language is terse, homely, and sometimes obscure, from the nature of the allusions and the expressions used, but his dialogues are the most dramatic in the Latin tongue. The *editio princeps* appeared at Rome in 1470; later editions are those of Isaac Casaubon (Par. 1605), Passow (Leip. 1809), Jahn (Leip. 1843), and Heinrich (Leip. 1844). P. has been frequently translated; as many as fourteen English, twenty French, and considerably more German versions, being known. The two best English ones are those by Dryden and Gifford.

PERSON (Lat. *persona*, a mask) has come, from its original signification, to be applied to the individual wearing the mask, and thus to mean in general an individual, or a numerically distinct being. Beyond the idea of individuality, it involves that of a sentient or intelligent nature, in which it differs from 'substance' or 'thing.' The theological use of the word, although strictly identical with its philosophical signification, is made difficult of apprehension from its being applied to the Christian doctrine of the Trinity, which in itself involves a mystery. Nevertheless, when theologians declare that there are Three Persons in one God, they intend to strictly convey that each of the Three Persons is a Being individually subsisting and numerically distinct; and the

difficulty of apprehension is derived, not from these terms, but from the reconciliation of the numerical distinction of Persons with the unity of the Divine Nature.

The name *Persona*, Person, was first applied to the Trinity by the Latins; the corresponding Greek word *Prosopon*, being of later use. The earlier Greek Fathers used the word *Hypostasis*, substance, where the Latins used *Persona*, and considerable controversy for a time grew out of this diverse use. It became apparent, however, that the difference was but of words; and after the condemnation of the Sabellian heresy (see **SABELLIANISM**), and still more after the council of Nicæa, all ambiguity of words being at an end, the controversy turned upon the substance of the doctrine, in the well-known form of the Arian controversy. See **ARIUS**.

PERSONAL ACTIONS, in English Law, are actions which are brought to try the right to damages for breach of contract, or for injuries to the person or personal estate; in contradistinction to real actions, which were designed to try the right and title to real property.

PERSONAL EXCEPTION means, in the Roman law, a ground of objection which applies to an individual, and prevents him doing something which, but for his conduct or situation, he might do. The term is adopted in the law of Scotland. In England, it is generally called an estoppel. Thus, a person who executes a deed is prevented by personal exception or estoppel from disputing the obligation thereby contracted, unless a case of fraud be made out.

PERSONALTY, in English Law, means all the property which, when a man dies, goes to his executor or administrator, as distinguished from the realty, which goes to his heir-at-law. Personality consists of money, furniture, stock in the funds; while realty consists of freehold land and rights connected with land. See **INTESTACY**, **KIN**, **NEXT OF**.

PERSONIFICATION (called by the Greeks *Prosopopœia*) is a figure of rhetoric by which inanimate objects, or mere abstract conceptions, are invested with the forms and attributes of conscious life. Oratory and poetry often derive great power and beauty from the employment of this figure. Nowhere do we find more sublime examples than in the Hebrew Scriptures, e.g., 'The sea saw it, and fled.' Such abstract conceptions as Wisdom, Justice, Charity, are often personified in the gravest and most argumentative compositions.

PERSONNEL, in speaking of an army, represents the officers and soldiers, as opposed to the *matériel*, in which are comprised the guns, provisions, wagons, and stores of every description.

PERSPECTIVE (Lat. *perspicio*, I look through), is the art of representing natural objects upon a plane surface in such a manner that the representation shall affect the eye in the same way as the objects themselves. The distance and position of objects affect both their distinctness and apparent form, giving rise to a subdivision of perspective into *linear perspective*, which, as its name denotes, considers exclusively the effect produced by the position and distance of the observer upon the apparent *form* and *grouping* of objects; while *aerial perspective* confines itself to their *distinctness*, as modified by distance and light. The necessity of attending to the principles of perspective in all pictorial drawing is apparent when we consider, for instance, that a circle, when seen obliquely, appears to be not a circle, but an ellipse, with its shortest diameter in line with the spectator, and its longest at right angles to this. A square, when looked at from a position opposite the center of one of its sides appears as a trapezoid, the sides which are perpendicular to the direction of vision appearing to be parallel, while the other two appear to converge to a point in front of the spectator, &c. For the same reason, two rows of parallel pillars of equal height, seen from a point between and equidistant from each row, appear not only to converge at the further end, but to become gradually smaller and smaller. An excellent idea of a perspective plan can be easily obtained by interposing a vertical transparent plane (as of glass—a window, for instance) between the observer and the objects of his vision, and supposing that the objects he sees are not seen *through* the glass, but painted on it.

A sketch made on a glass plane in this position by following with a pencil all the lines and shades of the objects seen through it, the eye being all the time kept quite steady, would form a picture in perfect perspective. In practice, however, it is found, unfortunately, that glass is not a suitable material for sketching on, and that the vertical position is not the most convenient; it is therefore preferable to make a careful study of the effects produced by change of position and distance on the appearance of objects in nature, and from the results of this to compile a body of rules, by the observance of which painters may be enabled to produce an effect true to nature. After the 'scope' (i. e., the number of objects to be introduced, and the distance at which they are to be viewed) of the picture has been determined, and before the design is com-

menced, it is necessary to draw upon the perspective plan three lines: 1. The *base line*, or *ground line*, which limits the sketch towards the operator, and is the base line of the picture. 2. The *horizontal line*, which represents the ordinary position of the sensible horizon. The height of the horizontal line is about one-third of the height of the picture, when the sketcher is placed at or little above the level of the horizon; but it may rise in a degree corresponding to his increase of elevation till it reaches near to the top of the perspective plan. The general rule is to have a high horizontal line when the view is taken, or supposed to be taken, from an eminence; but when the station is on a level, either actual or assumed, as is the case when a statue or a mountainous landscape is figured, the horizontal line must be low. The horizontal line in nearly all cases is supposed to be level with the spectator's eye. 3. The *vertical line*, which is drawn from the supposed position of the sketcher, perpendicular to the *ground* and *horizontal* lines, meeting the latter in a point which is called the *point of sight*, or center of the picture.

The vertical line has no representative in nature, and is merely a mechanical adjunct to the construction of the picture, all vertical lines in nature being parallel to it in the picture. The point of sight being the point directly opposite to the observer, it is properly placed in the center of the picture, for it is most natural that the view should lie symmetrically on each side of the principal visual line; but this is not by any means a universal rule, for we very frequently find it on the right or left side, but always, of course, on the horizontal line. All lines which in nature are perpendicular to the ground line, or to a vertical plane which is raised upon it as a base, meet in the point of sight, which is thus their *vanishing point* (see the line of the tops and bottoms of the pillars in fig. 1). The *points of distance* are two points in the hori-

Fig. 1.

Illustrating the more important points and lines; P.V.R. is the principal visual ray.

zontal line on each side of the point of sight, and in a 'direct' sketch are at a distance from it equal to the horizontal distance of the sketcher's eye from the ground line. The equality of distance of these points from the point of sight is not, however, necessary, as it occurs only in those cases where the lines, of which the points of distance are the *vanishing points*, are inclined (in nature) at an angle of 45° to the base line; but, in all cases, the two points of distance are about twice as far apart as the eye is from the picture. One important use of the points of distance is to define the distance of objects in a row (fig. 1) from each other. For this purpose, two points of distance are not necessary, as, when the position of one pillar is found, that of the one opposite is at once obtained by drawing a line parallel to the base or ground line. We have seen that the point of sight is the vanishing point of all level lines which meet the ground line or a vertical plane on it at right angles, and that the points of distance (in a *direct* picture) are the vanishing points of all lines which cut the ground line at an angle of 45° ; but there are many other groups of parallel lines in a picture which have different situations, and therefore different vanishing points. Such lines with their vanishing points (called, for distinction's sake, *accidental points*) are represented in fig. 2.

Fig. 2.

The lines O O converge to the accidental point aerial, and PP to the accidental point terrestrial.

If the accidental point is above the horizontal line, it is called the *accidental point aerial*—if below, the *accidental point terrestrial*; and a little consideration makes it evident that these points may

or may not be situated within the plane of the picture. Such are the points and lines necessary for the construction of a plan in true perspective; and from the above explanation, we may deduce the two general principles: 1. That all parallel straight lines in nature are no longer parallel when projected on the perspective plane, but meet in a point which is called the vanishing point, and is some one of the three above described, unless these lines happen to be also parallel to the ground line or the vertical line, in which case they remain parallel when transferred to the picture; and 2. That since the bodies drawn below the horizontal line are seen as if from above, those above as if from below, and those to the right and left of the point of sight as if observed from the left and right, it follows, that straight lines which in the picture are above the horizontal line lower themselves, those below raise themselves to it; those to the left, following the same law, direct themselves to the right, and *vice versa*.

Aërial perspective, consists in a modulation of the brightness and colors of objects in accordance with the state of the atmosphere, the depth of the body in the perspective plane (i. e., distance in nature from the ground line), and other accidents of place and time. As the distance of objects increases, their illuminated parts are made less brilliant, and their shaded parts more feeble. The bluish tint imparted by a large mass of the atmosphere to the bodies seen through it, is frequently imitated by the mixing of a slight tint of blue with the colors to be applied; a yellow object thus assumes a greenish tint; a red one, a violet tint, &c. The air, when charged with vapor, is represented by a diminution of the brightness of colors, and by the grayish tint imparted to them. But in this part of the subject, rules are of little avail, for experience alone can guide the painter in faithfully copying the myriad aspects presented by nature.

A thorough knowledge of perspective is a *sine quâ non* to the painter or designer, and though many are inclined to think it a superfluity, and that the sketcher has only to make use of his eyes, and copy justly, the very fact that such is their opinion, shows that they have never made the attempt; for it is impossible for the painter, and much more so for the designer, to execute a copy of nature with sufficient accuracy by the sole aid of the eye and hand, a fact that is unfortunately much too frequently proved by many of the sketches exhibited in fine-art collections. Perspective was known to the ancients, but seems to have become extinct during the disturbances that convulsed Italy, and was revived by Albert Dürer, Pietro del Borgo, and Bramantino of Milan (1440), whose body of rules was extended and completed by Peruzzi and Ubbaldi about 1600. Dr. Brook Taylor was the first Englishman who discussed the subject scientifically. Works on perspective are now abundant in every language.

PERSPIRATION. See SWEAT.

PERTH, a city, royal, municipal, and parliamentary burgh, and capital of the county of the same name, is situated on the right bank of the Tay, 45 miles north-north-west of Edinburgh by railway (through Fife). The charming scenery of the immediate vicinity; the Tay, a broad and noble river, sweeping southward along its eastern side; and the superb background of the Grampians on the north, render the site of the 'Fair City' exceedingly interesting and beautiful; while its rank as in some sort the ancient metropolis of Scotland, the important rôle it has played in the history of the country, and the picturesque associations with which history and fiction have invested it, claim for it a high rank among the cities of Scotland. A handsome bridge of nine arches, 880 feet in length, and stretching over a water-way 590 feet in width, connects the town with the suburb of Bridgend, on the left bank of the river. Further down, the Perth and Dundee Railway crosses the river on a fine stone and iron bridge, which also admits foot-passengers. The appearance and salubrity of P. are much enhanced by two beautiful public parks, called the North and South Inches. The water supply, obtained from the Tay, is filtered, raised by steam into two elevated reservoirs, and thence distributed over the town, rising to the upper stories of the highest houses.

Among the most interesting public buildings are the church of St. John, an ancient structure in the Pointed Style, surmounted by a massive square tower; the County Buildings, a Grecian edifice; the Town-house (part of which is as old as 1210); King James VI.'s Hospital; the Infirmary; and the local prison. At the head of the South Inch stands the Penitentiary, or General Prison, one of the largest buildings of the kind in Scotland, where all criminals sentenced to imprisonment for long periods are confined. The town also contains a statue of the late Prince Consort; Marshall's Monument, erected in honor of a former lord provost, and containing a public library and the Museum of the Antiquarian Society; the public seminaries, Sharp's and other educational

institutions. The river is navigable to P. for vessels of considerable burden. The linen and winey manufactures are thriving. There are dye-works, iron-foundries, breweries, &c.; but ship-building has declined. The salmon-fishery on the Tay is very valuable, the rental being upwards of £15,000. In 1880, 204 vessels, of 16,573 tons, entered and cleared the port. Six fairs are held annually, and horse-races take place every year on the North Inch. P. has a charter as a royal burgh from King William the Lion (1165—1214). It returns a member to the House of Commons. Pop. (1871) of royal and parliamentary burgh, 25,585; (1881) 28,948. There are above 20 places of worship. The city revenue in 1879—80 was £7380.

PERTH, THE FIVE ARTICLES OF, memorable in the ecclesiastical history of Scotland, were five articles agreed upon in a meeting of the General Assembly of the Church of Scotland, convened at Perth, by command of James VI., on 25th August 1618. These Articles enjoined kneeling at the Lord's Supper, the observance of Christmas, Good Friday, Easter, and Pentecost, and confirmation, and sanctioned the private administration of baptism and of the Lord's Supper. They were highly obnoxious to the Presbyterians of Scotland, not only on their own account, but as part of an attempt to change the whole constitution of the church; and because they were adopted without free discussions in the Assembly, and in mere compliance with the will of the king, who was also regarded as having unduly interfered with the constitution of the Assembly itself. They were, however, ratified by the parliament on 4th August 1621—a day long remembered in Scotland as *Black Saturday*—were enforced by the Court of High Commission, and became one of the chief subjects of that contention between the king and the people, which produced results so grave and sad for both, in the subsequent reign. The General Assembly of Glasgow, in 1638, declared that of Perth to have been 'unfree, unlawful, and null' and condemned the Five Articles.

PERTHES, FRIEDRICH CHRISTOPH, an eminent German publisher, distinguished not only in his professional capacity, but for his sincere piety and ardent patriotism, was born at Rudolstadt, 21st April 1772. In his 15th year, he was apprenticed to a Leipzig bookseller, with whom he remained six years, devoting much of his leisure time to the acquisition of knowledge. In 1793, he passed into the establishment of Hoffmann, the Hamburg bookseller; and in 1796, started business on his own account; and, by his keen and wide appreciation of the public wants, his untiring diligence, and his honorable reputation, he ultimately made it the most extensive of the kind in modern Germany. During the first few years or so of his Hamburg apprenticeship, his more intimate friends had been either Kantian or sceptical in their opinions, and P., who was not distinguished for either learning or speculative talent, had learned to think with his friends; but a friendship which he subsequently formed with Jacobi (q. v.), and the Holstein poet and humorist, Matthias Claudius, led him into a serious but liberal Christianity. The iron rule of the French in Northern Germany, and the prohibition of intercourse with England, nearly ruined trade, yet P., even in this great crisis of affairs, found ways and means to extend his. He endeavored to enlist the intellect of Germany on the side of patriotism, and in 1810 started the *National Museum*, with contributions from Jean Paul Richter, Count Stolberg, Claudius, Fouqué, Heeren, Sartorius, Schlegel, Görres, Arndt, and other eminent men. Its success was far beyond P.'s expectations, and encouraged him to continue his patriotic activity, till Hamburg was formally incorporated with the French empire. He subsequently took a prominent part in forcing the French garrison to evacuate Hamburg, 12th March 1813; and on its re-occupation by the French, he was one of the ten Hamburgers who were specially excepted from pardon.

After peace had been restored to Europe, P. steadily devoted himself to the extension of his business, and to the consolidation of the sentiment of German national unity, as far as that could be accomplished by literature and speech. In 1822, he removed to Gotha, transferring his Hamburg business to his partner Besser. Here he laid himself out mainly for the publication of great historical and theological works. His subsequent correspondence with literary, political, and theological nobilities—such as Niebuhr (one of his dearest friends), Neander, Schleiermacher, Lücke, Nitzsch, Tholuck, Schelling, and Umbreit—is extremely interesting, and throws a rich light upon the recent inner life of Germany. He died 18th May 1843.—See *Friedrich Perthes' Leben* (12th edit. 1853), written by his second son, Clemens Theodor Perthes, Professor of Law at Bonn, who died in 1867.—The uncle of Friedrich Christoph P. was JOHANN GEOR. JUSTUS PERTHES, who established a publishing and bookselling house at Gotha in 1785, which has acquired, in the hands of his sons, a great reputation, and from which issues the famous *Almanach de Gotha*. He died in 1816.

PERTHSHIRE, one of the most important counties in Scotland, is bounded on the S. by the shires of Stirling and Clackmannan; on the N. by Inverness and Aberdeen; on the W. by

Argyle and Dumbarton; and on the E. by Forfar, Fife, and Kinross. It extends from east to west about 70 miles, and from north to south about 66 miles. Its area is 2884 miles, or 1,814,063 acres, of which above 32,000 are covered with water. It is divided into the Highland and Lowland districts, the former occupying much the larger surface, and these are subdivided into 10 divisions—viz., Menteith, Strathearn, Gowrie, Stormont, Strathardle, Glenshee, Athole, Breadalbane, Rannoch, and Balquidder. P. from its insular position and other advantages, has a comparatively mild climate; and the soil, in Strathearn, Carse of Gowrie, and other less extensive tracts, being mostly composed of a rich loam, crops of all kinds are brought to the utmost perfection. These districts are also famed for their fruit and floral productions.

P. is not less distinguished for its magnificent mountain, lake, and river scenery. The Grampians here attain to nearly their maximum height, Ben Lawers being within a few feet of 4000 in altitude; while Ben More is 3843; and several others above 3000. The lakes are numerous, the principal of which are Lochs Tay, Erich, Rannoch, Tummel, Lydcock, Garry, Lyon, and Dochart. There are several streams of note, the principal being the Tay, which is fed by numerous other streams, and is said to discharge as much water into the sea as any other river in the kingdom. These lakes and streams afford excellent fishing, and the Tay is valuable for its salmon, yielding in rent about £15,000 a year.

The monuments of hoar antiquity to be found in this county afford an interesting field of investigation for the curious. Lying northward of the Roman wall, P. comprises the scenes of the last struggle for independence, which the inhabitants of the lowland districts of Scotland made against those formidable enemies of theirs who were regarded as invincible. The last battle fought by the Caledonians against the Romans was at Mons Graup, or rather, as it should be read, Graup, supposed to be indicated by the great camp at Ardoch, between Dunblane and Crieff, and which does not at all seem to be connected with the Grampian range. In this final struggle, the result of which was that the Lowlanders were defeated, Agricola commanded the conquering host, and the Caledonians were led by a chief named *Calgacus*.

The chief towns of P. are Perth, Coupar-Angus, Auchterarder, Crieff, Dunblane, and Blairgowrie. According to agricultural statistics taken in 1881, the number of acres under all kinds of crops, bare fallow, and grass, was 345,788; under corn crops, 105,013; under green crops, 53,303; clover, sainfoin, and grasses under rotation, 100,451; permanent pasture and meadow land (exclusive of heath or mountain land), 84,823. Horses used for agriculture, &c., 14,328; cattle, 76,634; sheep, 675,081; pigs, 7741. The valued rent of P. for 1674 was equal to £28,330; for 1879—1880, £890,995—exclusive of £110,047 for railways and water-works. The rate of assessment is: for prisons, 2s.; police, 6s. 2d.; lunacy, 5s.; sheriff court-houses, 2s.; bridge money, 1s.; contagious diseases, animals, 6d.; general, 9d.; and land valuation and voters, 7d. per £100.

The Old Red Sandstone, granite, and slate abound. In this county are situated some of the stateliest mansions in Scotland, but, except Scone Palace, none of them contain any historical memorials; and objects of antiquarian interest more recent than Roman roads and camps, are the Cathedrals of Dunblane and Dunkeld, and the Abbey of Culross. There are two royal burghs, Perth and Culross, besides which there are several villages of considerable size, where trade in flax, &c. is carried on to some extent. Pop. (1871) 127,768; (1881) 128,985.

PERTINAX, HELVIUS, Roman emperor, was born, according to Dio Cassius, at Alba-Pompeia, a Roman colony of Liguria, August 1, 126 A.D. He received a good education, and, entering the military service, rose through the various grades till he obtained the command of the first legion, at the head of which he signalized himself in Rætia and Noricum against the native tribes. In 179, he was chosen consul, aided to repress the revolt of Avitus in Syria, and was governor successively of the provinces of Mæsia, Dacia, and Syria. Being sent by the Emperor Commodus to take the command of the turbulent legions in Britain, these troops, against his will, proclaimed him emperor; on which he solicited to be recalled, and was appointed proconsul of Africa, prefect of Rome, and consul (a second time) in 192.

On the death of Commodus, his assassins almost forced P. to accept of the purple, which with great hesitation he did; but, in spite of his promise of a large donation, he was unable to gain over the prætorian guard. His accession was, however, hailed with delight by the senate and people, who were rejoiced to have, as ruler, an able captain, instead of a ferocious debauchee; and P., encouraged by this favorable reception, announced his intention of carrying out an extensive series of reforms, having reference chiefly to the army, in which he hoped to re-establish the ancient Roman discipline. Unfortunately for his reforms and himself, he was attacked by a band of the rebellious prætorians, two months and twenty-seven days after his accession; and dis-

daining to flee, was slain, and his head carried about the streets of Rome in triumph. From his history, nothing can be gathered respecting his character and talents (except in military affairs); but the respect and esteem in which he was held by the senate and people of Rome, argue well in favor of his disposition.

PERTURBATIONS, in Physical Astronomy, are the disturbances produced in the simple elliptic motion of one heavenly body about another, by the action of a third body, or by the non-sphericity of the principal body. Thus, for instance, were there no bodies in space except the earth and moon, the moon would describe accurately an ellipse about the earth's center as focus, and its radius-vector would pass over equal areas in equal times; but only if both bodies be homogeneous and truly spherical, or have their constituent matter otherwise so arranged that they may attract each other as if each were collected at some definite point of its mass. The oblateness of the earth's figure, therefore, produces perturbations in what would otherwise be the fixed elliptic orbit of the moon. Again, when we consider the sun's action, it is obvious that in no position of the moon can the sun act equally upon both earth and moon; for at new moon, the moon is nearer to the sun than the earth is, and is therefore more attracted (in proportion to its mass) than the earth—that is, the *difference* of the sun's actions on the earth and moon is equivalent to a force tending to draw the moon away from the earth.

At full moon, on the other hand, the earth (in proportion to its mass) is more attracted than the moon is by the sun; and the perturbing influence of the sun is again of the nature of a force tending to separate the earth and moon. About the quarters, on the other hand, the sun's attraction (mass for mass) is nearly the same in amount on the earth and moon, but the *direction* of its action is not the same on the two bodies, and it is easy to see that in this case the perturbing force tends to bring the earth and moon nearer to each other. For any given position of the moon, with reference to the earth and sun, the *difference* of the accelerating effects of the sun on the earth and moon is a disturbing force; and it is to this that the perturbations of the moon's orbit, which are the most important, and amongst the most considerable, in the solar system, are due. [By the word *difference*, just employed, we are of course to understand, not the arithmetical difference, but the resultant of the sun's direct acceleration of the moon, combined with that on the earth reversed in direction and magnitude; as it is only with the *relative* motions of the earth and moon that we are concerned.] This disturbing force may be resolved into three components; for instance, we may have one in the line joining the earth and moon, another parallel to the plane of the ecliptic, and perpendicular to the moon's radius-vector, and the third perpendicular to the plane of the ecliptic. The first component, as we have already seen, tends to separate the earth and moon at new and full, and to bring them closer at the quarters; but during a whole revolution of the moon, the latter tendency is more than neutralized by the former; that is, in consequence of the sun's disturbing force, the moon is virtually less attracted by the earth than it would have been had the sun been absent. The second component mainly tends to accelerate the moon's motion in some parts of its orbit, and to retard it at others. The third component tends, on the whole, to draw the moon towards the plane of the ecliptic. We cannot, of course, enter here into even a complete sketch of the analysis of such a question as this; but we may give one or two very simple considerations which will, at all events, indicate the nature of the grand problem of perturbations.

The method, originally suggested by Newton, which is found on the whole to be the most satisfactory in these investigations, is what is called the *Variation of Parameters*, and admits of very simple explanation. The path which a disturbed body pursues is, of course, no longer an ellipse, nor is it in general either a plane curve or re-entrant. But it may be considered to be an ellipse which is undergoing slow modifications in form, position, and dimensions, by the agency of the disturbing forces. In fact, it is obvious that any small arc of the actual orbit is a portion of the elliptic orbit which the body would pursue for ever afterwards, if the disturbing forces were suddenly to cease as it moved in that arc. The *parameters*, then, are the elements of the orbit; that is, its major axis, eccentricity, longitude of apse, longitude of node, inclination to the ecliptic, and epoch; the latter quantity indicating the time at which the body passed through a particular point, as the apse, of its orbit. If these be given, the orbit is completely known, with the body's position in it at any given instant. If there be no disturbing forces, all these quantities are constant; and therefore, when the disturbing forces are taken into account, they change very slowly, as the disturbing forces are in most cases very small. To give an instance of the nature of their changes, let us roughly consider one or two simple cases. First, to find the nature of some of the effects of a disturbing force acting in the radius-vector, and tending to draw the disturbed, from the central, body. Let S be the focus, P the nearer apse, of the undisturbed elliptic orbit. When the moving body passes the point

M, the tendency of the disturbing force is to make it describe the dotted curve in the figure—i. e., the new direction of motion will make with the line MS an angle more nearly equal to a right angle than before; and therefore the apse Q, in the disturbed orbit will be sooner arrived at than P. would have been in the undisturbed orbit—that is, the apse *regreeds*, or revolves in the contrary sense to that of M's motion. Similarly, the effect at M₁ is also to

Fig. 1.

make the apse regrede to Q₁. At M₂ and M₃, on the other hand, the tendency is to make the apse progred. Also, as the velocity is scarcely altered by such a force, the major axis remains unaltered. Thus at M the eccentricity is diminished, and at M₁ increased, since the apsidal distance is increased at M, and diminished at M₁.

Next, consider a tangential accelerating force. Here the immediate effect is to increase the velocity at any point of the orbit, and therefore to make it correspond to a larger orbit, and consequently, a longer periodic time. Conversely, a retarding force, such as the resistance of a medium, diminishes the velocity at each point, and thus makes the motion correspond to that in an ellipse with a less major axis, and therefore with a diminished periodic time. This singular result, that the periodic time of a body is *diminished* by resistance, is realized in the case of Encke's comet, and this observed effect furnishes one of the most convincing proofs of the existence of a resisting medium in interplanetary space.

Again, the effect of a disturbing force continually directed towards the plane of the ecliptic, is to make the node regrede. Thus, if N'N represent the ecliptic, NM a portion of the orbit, the tendency of the disturbing force at M is to make MQ the new orbit, and therefore N' the node. Thus the node regreeds, and the inclination of the orbit to the ecliptic is diminished, when the planet has just passed the ascending node. In the second figure, let M, be a position of the planet near the descending node N₁. The effect of the dis-

Fig. 2.

Fig. 3.

turbing force is to alter the orbit to MN'₁. Thus, again, the node regreeds, but the inclination is increased. If NN' and N₁N₁' in these figures represent the earth's equator, the above rough sketch applies exactly to the case of the moon as disturbed by the oblateness of the earth. The reaction of the moon on the earth gives rise to the Precession of the Equinoxes (q. v.).

By processes of this nature, Newton subjected the variation of the elements of the moon's orbit to calculation, and obtained the complete explanation of some of the most important of the lunar inequalities. See MOON. Others of them—for instance, the rate of progression of the apse—cannot be deduced with any accuracy by these rough investigations, but tax, in some cases, the utmost resources of analysis. Newton's calculation of the rate of the moon's apse was only about half the observed value; and Clairaut was on the point of publishing a pamphlet, in which a new form was suggested for the law of gravitation, in order to account for the deficiency of this estimate; when he found, by carrying his analysis further, that the expression sought is obtainable in the form of a slowly converging series, of which the second term is nearly as large as the first.

The error of the modern Lunar Tables, founded almost entirely on analysis, with the necessary introduction of a few data from observation, rarely amounts to a second of arc; and the moon's place is predicted four years beforehand, in the *Nautical Almanac*, with a degree of precision which no mere observer could attain even from one day to the next. This is the true proof, not only

of the law of gravitation, but of the Laws of Motion (q. v.), upon which, of course, the analytical investigation is based.

With respect to the mutual perturbations of the planets, we may merely mention that they are divisible into two classes, called *periodic* and *secular*. The former depend upon the configurations of the system—such, for instance, is the diminution of the inclination of the moon's orbit, after passing the ascending node on the earth's equator, already mentioned, or its increase as the moon comes to the descending node. The secular perturbations depend upon the period in which a complete series of such alternations have been gone through, and have, in the case of the planets, complete cycles measured by hundreds of years.

A very curious kind of perturbation is seen in the *indirect* action of the planets on the moon. There is a secular change of the eccentricity of the earth's orbit, due to planetary action, and this brings the sun, on the average, nearer to the earth and moon for a long period of years, then for an equal period takes it further off. One of the effects of the sun's disturbing force being, as we have seen, to diminish, on the whole, the moon's gravity towards the earth, this diminution will vary in the same period as the eccentricity of the earth's orbit; and therefore the moon's mean motion will be alternately accelerated and retarded, each process occupying an immense period.

With special reference to the planetary motions, we may notice that the major axis of each planetary orbit is free from all secular variations; and those affecting the inclination and eccentricity are confined within small limits, and ultimately compensate themselves. These facts, which have been clearly and beautifully demonstrated by Laplace and Lagrange, assure the stability of the planetary orbits, if we neglect the effects of resistance due to the interplanetary matter; which, however, must, in the long run, bring all the bodies of the system into collision with the sun, and finally stop the rotation of the sun itself.

Newton commenced the investigation of perturbations by considering those of the moon; Euler followed with a calculation of Saturn's inequalities; while Clairaut, D'Alembert, and others successively gave those of the other planets.

Every one knows that it was by observing the perturbations of Uranus, and thence discovering the direction of the disturbing force, that Adams and Leverrier were led to their great and simultaneous discovery of the planet Neptune.

PERU, an important maritime republic of South America, bounded on the N. by Ecuador, on the W. by the Pacific, on the S. and S.E. by Bolivia, and on the E. by Brazil. It lies in lat. $3^{\circ} 25'$ — $21^{\circ} 30'$ S., and in long. 68° — $81^{\circ} 20'$ W. The general outline resembles a triangle, the base of which is formed by the boundary-line between P. and Ecuador on the north. Its area is above 500,000 sq. m.; and according to a census made in 1876, the population is 2,720,735, not including wild Indians. On the east side of the Andes, and between the Amazon and the Purus, there is a wide and unexplored expanse of country, upon which both P. and Brazil have claims, though the boundary is now generally regarded as marked by the Rio Javary. The country is 1100 miles in length, 780 miles in extreme breadth along the northern boundary, but is little more than 50 miles wide in the extreme south. Following the general direction, and not including windings, the coast-line is 1660 miles in length. The shores are in general rocky and steep; in the south, lofty cliffs rise from the sea, and, in some places, the water close inshore has a depth of from 70 to 80 fathoms.

Further north, however, sandy beaches occur, and in the extreme north, the shores are often low and sandy, and covered with brushwood. Owing to the comparative unfrequency of bays and inlets along the coast, the harbors are few and unimportant. Those of Callao (the port of Lima) and Payta afford the most secure anchorage, and the others are Trujillo, Cañeto, Pisco, Camaná, Islay, Ilo, Arica, and Iniquique. Landing by boats is always dangerous, on account of the dreaded surf, occasioned by the swell of the Pacific, which perpetually beats upon the coast; and when goods or passengers require to be landed on unsheltered shores, recourse is had to the primitive *balsas*, or rafts, worked by the natives, and capable of carrying two or three persons.

Islands.—The islands on the Peruvian coast, although valuable, are extremely few in number, and small in extent. In the north, are the Lobos (i. e., *Seal*) Islands, forming a group of three, and so called from the seals which frequent them. The largest of them, Lobos de Tierra, is 5 miles long by 2 miles broad, and the others, lying 30 miles south-west, are much smaller. On their eastern sides, they are covered with guano, and the quantity on the whole group, when it began to be exported from them, was stated to be 4,000,000 tons. The islands of Macabi and Guañope, near the Lobos, were originally calculated to contain 2,280,000 tons of guano; but the guano exported has very greatly exceeded that amount, and in 1872, it was calculated that there were still 750,000 tons of guano on the former and 500,000 tons on the latter. The Chincha Islands, three in number, and the most famous

of the whole, which began to supply Europe in 1841, had very little guano left on them in 1873. They are called the North, Middle, and South Islands respectively. Each presents, on the eastern side, a wall of precipitous rock, with a general slope towards the western shore. The cavities and inequalities of the surface used to be filled with guano, and this material covered the western slopes to within a few feet of the water's edge. There was no vegetation. The North Island has an area of 202 acres. It is formed of felspar and quartz, and is slowly but certainly decreasing in size. This island used to be wholly covered with thick layers of guano, which was quarried in some places to a depth of 80 feet. Hundreds of convicts were employed in cutting the guano and loading the vessels.

The Chincha Islands ceased to be worked for foreign export in 1872, and now guano is only taken for Peruvian use from the northern island, where there is still supposed to be 150,000 tons. In 1874, however, valuable new deposits of guano were discovered on the southern coast of Peru, which are estimated to contain about 8,000,000 tons.

The grand physical feature of the country, and the source of all its mineral wealth, is the great mountain system of the Andes. A general description of the formation and character of the Peruvian Andes is given under the article *ANDES* (q. v.).

Surface, Soil, and Climate.—The surface of P. is divided into three distinct and well-defined tracts or belts, the climates of which are of every variety from torrid heat to arctic cold, and the productions of which range from the stunted herbage of the high mountain-slopes, to the oranges and citrons, the sugar-canes and cottons, of the luxuriant tropical valleys. These three regions are the *Coast*, the *Sierra*, and the *Montaña*.—The *Coast* is a narrow strip of sandy desert between the base of the Western Cordillera and the sea, and extending along the whole length of the country. This tract, varying in breadth from 30 to 60 miles, slopes to the shore with an uneven surface, marked by arid ridges from the Cordillera, and with a rapid descent. It is for the most part a barren waste of sand, traversed, however, by numerous valleys of astonishing fertility, most of which are watered by streams that have their sources high on the slopes of the Cordillera. Many of the streams are dry during the greater part of the year. Between these valleys extend deserts, which are sometimes 90 miles in width. These are perfectly trackless, being covered with a fine, shifting, yellow sand, which is often carried about by the wind in pillars of from 80 to 100 feet in height.

In the coast-region, properly so called, rain is unknown. This is caused by the coast of P. being within the region of perpetual south-east trade-winds. These winds, charged with vapors from the Atlantic, strike upon the east coast of South America, and traverse that continent obliquely, distributing rains over Brazil. But their vapor is thoroughly condensed by the lofty Cordilleras, and their last particles of moisture are exhausted in powdering the summits of these ranges with snow, after which they fall down upon the coast of P., cool and dry. The want of rain, however, is compensated for to some extent by abundant and refreshing dews, which fall during the night. The climate of the coast is modified by the cool winds. In the valleys, the heat, though considerable, is not oppressive. The highest temperature observed at Lima in summer is 85° , the lowest in winter is 61° F.

The *Sierra* embraces all the mountainous region between the western base of the maritime Cordillera and the eastern base of the Andes, or the Eastern Cordillera. These ranges are, in this country, about 100 miles apart on an average, and have been estimated to cover an area of 200,000 square miles. Transverse branches connect the one range with the other, and high plateaux, fertile plains, and deep tropical valleys lie between the lofty outer barriers. The superiority in elevation alternates between the two principal ranges. The east range, or, as it is generally called, the Andes, has the superiority in height in the southern half of this mountain system. It abuts upon the plain, from the Bolivian frontier, in a majestic mass, surmounted by stupendous pinnacles, rugged in outline, and most frequently rising in splintered needle-like peaks, covered with snow. North of lat. 13° S., however, the Western Cordillera assumes the grander character, and preserves it until it crosses the northern frontier. The scenery of the Western Cordillera is broader and more massive in character, and its summits less pointed than those of the Andes.

Rugged paths, sometimes so narrow as barely to afford footing to the mules which are invariably used in such ascents, lead up its steep sides. Occasionally, from these narrow passes, gaping and apparently bottomless precipices slide perpendicularly downward from the very feet of the traveler, and the prospect is rendered still more hideous by the distant roar of a torrent, hidden by mists, at the bottom of the ravine. Occasionally, also, the mountain route leads over abysses 500 feet in depth, across which, by way of bridge, a few poles are thrown, which roll about in an uncomfortable manner under the feet. In traversing these dangerous passes, which line the huge rocks like aerial threads,

the traveler often comes upon scenery of the most picturesque and beautiful description. The clefts and sides of the hills, even at altitudes which might be called alpine, are clothed with wild-flowers, many of which, now long cultivated in Britain, have become highly prized among us as garden-plants. Verbenas, lupines, blue and scarlet salvias, fuchsias, calceolarias, and the fragrant heliotrope, add a sense of beauty to the sense of power which the stupendous scenery imparts. The following are the most striking and distinctive physical features of the Sierra, beginning from the south: 1. The plain of Titicaca, partly in P., and partly in Bolivia, is enclosed between the two main ridges of the Andes, and is said to have an area of 30,000 miles—greater than that of Ireland. In its center is the great Lake Titicaca, 12,846 feet above sea-level, or 1600 feet above the loftiest mountain pass (the Col of Mont Cervin) of Europe. The lake is 115 miles long, from 30 to 60 miles broad, from 70 to 180 feet deep, and 400 miles in circumference. Its shape is irregular; it contains many islands, and several peninsulas abut upon its waters. 2. The Knot of Cuzco. The mountain-chains which girdle the plain of Titicaca trend toward the northwest, and form what is called the Knot of Cuzco. The Knot comprises six minor mountain-chains, and has an area thrice larger than that of Switzerland. Here the valleys enjoy an Indian climate, and are rich in tropical productions; to the north and east of the Knot extend luxuriant tropical forests, while the numberless mountain-slopes are covered with waving crops of wheat, barley, and other cereals, and with potatoes; and higher up, extend pasture-lands where the vicuña, and alpaca feed.

3. The valley of the Apurimac, 30 miles in average breadth, and extending north-west for about 300 miles. This valley is the most populous region of Peru. 4. The Knot of Pasco. From Cuzco proceed two chains toward the north-west; they unite again in the Knot of Pasco. This Knot contains the table-land of Bombon, 12,300 feet above sea-level; as well as other table-lands at a height of 14,000 feet, the highest in the Andes; otherwise, however, the physical features of the country resemble those of the vicinity of Cuzco. 5. The vale of the river Marañon. This valley, which is upwards of 300 miles in length, is narrow, deep, and nearer the equator than any other valley of the Sierra, and consequently, it is the hottest portion of this region; and its vegetation is thoroughly tropical in character. The conformation of the surface of the Sierra is of the most wonderful description. After the table-lands of Tibet, those of the Peruvian Andes are the highest in the world; but, unlike those of Tibet, which are mere grassy uplands, the table-lands of P. are the seat of a comparatively high civilization, and are studded over with towns and villages, perched on heights exceeding in elevation the summits of the Jungfrau and the Wetterhorn. Nor are such towns the mere eyries of miners who are tempted to ascend thus high in search of the precious metals; for, even at this elevation, the climate is pleasant, and wheat, maize, barley, rye, and potatoes thrive well. The city of Cuzco, situated in a region of rare beauty, and enjoying a temperate climate, is 11,380 feet above sea-level, or 2000 feet higher than the Great St. Bernard. The climate of the Sierra, however, is not always so charming. In general terms, it may be described as mild and variable, with moderate rains. In the district of Paucartambo, rain falls 300 days in the year. A country, however, of such an uneven surface, of snow-covered peaks and tropical valleys, embraces every variety of climate.

In all the lower regions of the country the climate is warm, but healthy; in the uplands, and on the highest plateaux, it is often inclement. Violent storms beat upon the plain of Titicaca; and terrific tempests, accompanied by thunder and lightning, roll frequently around the table-lands of Pasco (q. v.); where, indeed, the climate is so cold, that but for the mines, which have attracted hither a numerous population, this region might have remained uninhabited. At the height of 9000 feet above sea-level, the mean temperature is 60° Fahr., and the variation throughout the year is not great. The highest peaks of the country reach to upwards of 22,000 feet, and many peaks in both ranges are from 17,000 to 20,000 feet high. In the Western Cordillera, and in the south of the country, are four volcanoes—Candarave, Ubina, Omate, and Arequipa. The soil of the Sierra is of great variety; but wherever it is cultivated, it is productive.

The *Montaña*, forming two-thirds of the entire area of the country, stretches away for hundreds of leagues eastward from the Andes to the confines of Brazil. On the N., it is bounded by the Amazon, on the S. by Bolivia. It consists of vast impenetrable forests and alluvial plains, is rich in all the productions of tropical latitudes, is of inexhaustible fertility, and teems with animal and vegetable life. It is still, however, almost wholly unproductive to man. The silence of its central forests has never been disturbed by the civilized explorer, and its only human inhabitants are a few scattered tribes of Indians. The *Montaña* is watered by numberless streams, and by a large number of important rivers. It belongs wholly to the basin of the Amazon.

Along the head-waters of the Purus, which, flowing through beautiful forest-covered plains, approaches to within 60 miles of Cuzco, there were at one time numerous Spanish farms, where great tracts of forests had been cleared, and where crops of coco, cocoa, sugar, and other tropical productions, were regularly raised. These farms have since 1861 been abandoned, and the encroaching forest has already obliterated their sites. The upper waters of the Purus are the headquarters of a savage and barbarously cruel tribe of wild Indians called Chunchos.

These untamable savages have shown the greatest hostility to the advance of civilization. They murdered the settlers, or drove them to take refuge in some less advanced settlement. When Mr. Markham visited this region in 1853, a few farms still existed; in a paper, however, which he communicated to the *Journal of the Royal Geographical Society*, and which is dated 1861, he further reported that the Chunchos have finished their barbarous work, for the settlers have either all been massacred or driven back from the forest, so that now not a single settlement remains. The rich valleys of Paucartambo, once covered with flourishing Spanish farms, have again become one vast tropical forest. The virgin soil of the *Montaña* is of amazing fertility; while its climate, though not oppressively hot, is healthy. The forests consist of huge trees, of which some are remarkable for the beauty of their wood, others for their valuable gums and resins, and others as timber trees. A rank undergrowth of vegetation covers the country, and the trees are often chained together and festooned with parasites and closely-matted creepers. In this region, for the most part undisturbed by the voice of man, civilized or savage, animal life flourishes in endless variety, and birds of the brightest plumage flit among the foliage. Among the products which are yielded here in spontaneous abundance, are the inestimable Peruvian bark (see *CINCHONA*), India-rubber, gum-copal, vanilla, indigo, copiba, balsam, cinnamon, sarsaparilla, ipecacuanha, vegetable wax, &c. On the western fringe of the *Montaña*, where there are still a few settlements, tobacco, sugar, coffee, cotton, and chocolate, are cultivated with complete success.

Hydrography.—The hydrography of P. may be said to be divided into three systems—those of Lake Titicaca, the Pacific, and the Amazon. The streams that flow into Lake Titicaca are few and inconsiderable. The rivers which, having their sources in the Western Cordillera, flow west into the Pacific, are about 60 in number; but many of them are dry in summer, and even the more important are rapid and shallow, have a short course, are not navigable even for canoes, and are mainly used for the purpose of irrigation. All the great rivers of Peru are tributaries of the Amazon. The Marañon, rising between the Eastern and Western Cordilleras, and flowing tortuously to the north-north-west, is generally considered to be the head-water of the Amazon (q. v.). The Huallaga rises near the town of Huanuco, and flows northward to the Amazon. It is navigable for 600 miles, the head of its navigation (for canoes) being at Tingo Maria, within 100 miles of its source. The Yucayali, or Ucayali, an immense river, enters the Amazon 210 miles below the Huallaga. Its tributaries and upper-waters, among which are the Pampas and the Apurimac, drain the greater portion of the Peruvian Sierra. The Purus, which reaches to the valleys of Paucartambo, within 60 miles of Cuzco, has recently been explored. We know several of its sources, and that it enters the Amazon by four mouths, a little above Barra. It flows through what is perhaps the richest and most beautiful region of Peru. Many attempts have been made to explore this river, but none were successful till Mr. Chandiess (1865–1866) explored it and its tributary, the Aguiré. Sailing down the Rio Negro, from Manos to the Amazon, he reached the mouth of the Purus, and ascended it a distance of 1866 miles. He found that it flowed in a tortuous course through a rich alluvial plain, and that the few Indians on its upper course were still as primitive as is indicated by the use of only stone hatchets. He ascertained that the Rio Madre de Dios is not the head-water of the Purus. He then ascended the Aguiré, the principal affluent of the Purus, in the hope that it might afford communication with that south Peruvian river, but failed, owing to difficulties insuperable by him, to settle the question.

Productions, Exports and Imports, Revenue, &c.—The wealth and resources of P. consist, not in manufactures, but entirely in mineral, vegetable, and animal products. As no statistics are taken in the country, it is impossible to give the quantity and value of the productions, and of the exports and imports, even approximately. Of the precious metals, the production has greatly fallen off since P. became an independent state; and this country, which once stood in the same relation to Spain that Australia does to Great Britain, now contributes little to the metallic wealth of the world. The immense stores of gold and silver found here by the Spanish invaders represented the accumulation of centuries, and that among a people who used the precious metals only for the purposes of ornamentation. Nevertheless, P. possesses vast metallic riches. The Andes abound in mines of gold, silver, copper, lead, bismuth, &c.; and in the *Montaña*, gold is said to exist in abun-

dance in veins and in pools on the margins of rivers. The public revenue of P. is derived mainly from the sale of guano, and only to a small extent from customs. The total annual exports of P. are valued at about £7,500,000; and P. imports yearly about £1,000,000 worth of British goods. The actual revenue in 1875 was £6,263,320; the expenditure was £5,739,100. P. has a considerable public debt, divided into internal and external: the former, exclusive of a floating debt of unknown amount, is estimated at £2,500,000; the latter made up of sundry loans amounting to £49,010,000. The metric system of weights and measures was established by law in 1860, but has not yet come into general use. Besides the precious metals, P. possesses other most important mineral resources.

In addition to the guano, to which allusion has already been made, another important article of national wealth is nitrate of soda, which is found in immense quantities in the province of Tarapaca. This substance, which is a powerful fertilizer (see NITRATE), is calculated to cover, in this province alone, an area of 50 square leagues, and the quantity has been estimated at 63,000,000 tons. Here also great quantities of borax are found. The working of this valuable substance, however, is interdicted by government, which has made a monopoly of it, as it has of the guano; but such small parcels of it as have been exported bring about £30 per ton in the English market. In 1878 there were in P. 1200 miles of railway completed, and several hundreds in course of construction, including a line across the summit of the Cordillera de los Andes, and presenting engineering difficulties even more extraordinary than those overcome in the Mont Cenis Tunnel.

The vegetable productions of P. are of every variety, embracing all the products both of temperate and tropical climes. The European cereals and vegetables are grown with perfect success, together with maize, rice, pumpkins, tobacco, coffee, sugar-cane, cotton, &c. Fruits of the most delicious flavor are grown in endless variety. Cotton, for which the soil and climate of P. are admirably adapted, is now produced here in gradually increasing quantity. The land suited to the cultivation of this plant is of immense extent, and the quality of the cotton grown is excellent. The animals comprise those of Europe, together with the Llama (q. v.) and its allied species. Although P. produces so much excellent wool, almost the whole of the woollen fabrics used as clothing by the Indians are manufactured in Yorkshire, England.

Ancient Civilization and History.—P., the origin of whose name is unknown, is now passing through its third historical era, and is manifesting its third phase of civilization. The present era may be said to date from the conquest of the country by the Spaniards in the early part of the 16th c.; the middle era embraces the rule of the Incas; and the earliest era, about which exceedingly little is known, is that Pre-Incarial period, of unknown duration, during which a nation or nations living in large cities, flourished in the country, and had a civilization, a language, and a religion different, and perhaps in some cases even more advanced than those of the Incas who succeeded them, and overran their territories. Whence these Pre-Incarial nations came, and to what branch of the human family they belonged, still remain unanswered questions. Their existence, however, is clearly attested by the architectural remains, sculptures, carvings, &c., which they have left behind them. Ruins of edifices constructed both before the advent of the Incas, and contemporary with, and independently of, them, are found everywhere throughout the country. On the shores of Lake Titicaca, for example, are the ruins of Tia-Huanacu, consisting of sculptured monolithic doorways, one of which is 10 feet high, and 13 feet wide; of pillars, 21 feet high, placed in lines at regular distances; and of immense masses of hewn stone, some 38 feet long by 18 broad. In 1846, several colossal idols were excavated, some being 30 feet long, 18 wide, and 6 thick. The idols are in the form of statues, and the ears are not enlarged by the insertion in the lobes of silver rings, as those of sculptured figures executed in Incarial times invariably are. The ancient fragments of buildings on these shores were beheld with astonishment by the earliest of the Incas, who, by their own confession, accepted them as models for their own architecture.

The name Tia-Huanacu is comparatively modern, having been conferred by one of the Incas; neither history nor tradition has handed down the original name. The ruins stand at a height of 12,930 feet above sea-level, and one of the many mysteries which have crowded around this ancient site is, that this spot, in the midst of what is now generally a frozen desert, and where the rarity of the air must be so great as to be hurtful, should have been chosen as the seat, as it is generally believed to have been, of an ancient government. Of the character and degree of the civilization of the Pre-Incarial races, almost nothing is known. It is worthy of note, however, that at Pachacamac, 25 miles south of Lima, where there are the remains of a now wholly deserted city, and of a great temple, the religion seems to have been a pure Theism; for when the Peruvians of Cuzco carried their victorious

arms across the Cordilleras to this district, they beheld this temple (the doors of which are said to have been of gold inlaid with precious stones) with astonishment, not only because it rivalled if not surpassed in splendor the famous Temple of the Sun at Cuzco, but because it contained no image or visible symbol of a god. It was raised in honor of an invisible and mysterious deity, whom the inhabitants called Pachacamac, the Creator of the World (from two words of the ancient Peruvian language, *Pacha*, the earth; and *Camac*, participle of the verb *Camani*, to create). The Peruvians did not dare to destroy this temple, but contented themselves with building by its side a Temple of the Sun, to the worship of which they gradually won over the inhabitants.—See Bollaert's *South America* (1860); Squier's *Peru* (1876); Markham's *Peru* (1880); Gailenga's *South America* (1880); Reiss and Stübel, *Peruvian Antiquities* (1881).

Regarding the origin of the Incas, nothing definite can be said. We have no authorities on the subject save the traditions of the Indians, and these, besides being outrageously fabulous in character, are also conflicting. It appears, however, from all the traditions, that Manco, the first Inca, first appeared on the shores of Lake Titicaca, with his wife Mama Oello. He announced that he and his wife were children of the Sun, and were sent by the glorious Inti (the Sun) to instruct the simple tribes. He is said to have carried with him a golden wedge, or, as it is sometimes called, a wand. Wherever this wedge, on being struck upon the ground, should sink into the earth, and disappear for ever, there it was decreed Manco should build his capital. Marching northward, he came to the plain of Cuzco, where the wedge disappeared. Here he founded the city of Cuzco, became the first Inca (a name said to be derived from the Peruvian word for the Sun), and founded the Peruvian race, properly so called. Manco, or Manco Capac (i. e., Manco the Ruler), instructed the men in agriculture and the arts, gave them a comparatively pure religion, and a social and national organization; while his wife, Mama Oello, who is also represented as being his sister, taught the women to sew, to spin, and to weave. Thus, the Inca was not only ruler of his people, but also the father and the high-priest. The territory held by Manco Capac was small, extending about 90 miles from east to west, and about 80 miles from north to south. After introducing laws among his people, and bringing them into regularly organized communities, 'he ascended to his father, the Sun.' The year generally assigned as that of his death, after a reign, of forty years, is 1062 A.D. The progress of the Peruvians was at first so slow as to be almost imperceptible.

Gradually, however, by their wise and temperate policy, they won over the neighboring tribes, who readily appreciated the benefits of a powerful and fostering government. Little is clearly ascertained regarding the early history of the Peruvian kingdom, and the lists given of its early sovereigns are by no means to be trusted. They invented no alphabet, and therefore could keep no written record of their affairs, so that almost all we can know of their early history is derived from the traditions of the people, collected by the early Spaniards. Memoranda were indeed kept by the Peruvians, and, it is said, even full historical records, by means of the *quipu*, a twisted woollen cord, upon which other smaller cords of different colors were tied. Of these cross threads, the color, the length, the number of knots upon them, and the distance of one from another, all had their significance; but after the invasion of the Spaniards, when the whole Peruvian system of government and civilization underwent dislocation, the art of reading the quipus, seems either to have been lost, or was effectually concealed. Thus it is that we have no exact knowledge of Peruvian history further back than about one century before the coming of the Spaniards. In 1453, Tupac Inca Yupanqui, the eleventh Inca, according to the list given by Garcilasso de la Vega, greatly enlarged his already wide-spread dominions. He led his armies southward, crossed into Chili, marched over the terrible desert of Atacama, and penetrating as far south as the river Maule (lat. 36° S.), fixed there the southern boundary of Peru. Returning, he crossed the Chilean Andes by a pass of unequalled danger and difficulty, and at length regained his capital, which he entered in triumph. While thus engaged, his son, the young Huayna Capac, heir to the fame as well as the throne of his father, had marched northward to the Amazon, crossed that barrier, and conquered the kingdom of Quito.

In 1475, Huayna Capac ascended the throne, and under him the empire of the Incas attained to its greatest extent, and the height of its glory. His sway extended from the equatorial valleys of the Amazon to the temperate plains of Chili, and from the sandy shores of the Pacific to the marshy sources of the Paraguay. Of this immense territory, Cuzco, as its name implies (the word signifies navel), was the great center; great roads branched off from it to the north, south, east, and west, and ramified through every part of the kingdom. The greatest highway of the country was that which led from Quito through Cuzco into the Chilean dominions. In its construction, galleries were cut for leagues through the living rock; rivers were crossed by bridges of plaited osiers,

that swung in the air; precipices were ascended by staircases artificially cut, and valleys were filled up with solid masonry. It was from 1500 to 2000 miles long, was about 20 feet broad, and was built of heavy flags of freestone. Upon all the great routes were posts or small buildings, about five miles apart, attached to which were a number of runners, whose business it was to carry forward the dispatches of government. By means of these messengers, fresh fish caught on one day at Lurin, on the Pacific, is said to have been eaten the next day at Cuzco. The distance between these places is 300 miles, and the road traverses the wildest and most mountainous country in the world. Order and civilization accompanied conquest among the Peruvians, and each tribe that was vanquished found itself under a careful paternal government, which provided for it, and fostered it in every way.

The government of P. was a pure but a mild despotism. The Inca, as the representative of the Sun, was the head of the priesthood, and presided at the great religious festivals. He imposed taxes, made laws, and was the source of all dignity and power. He wore a peculiar head-dress, of which the tasselled fringe, with two feathers placed upright in it, were the proper insignia of royalty. Of the nobility, all those descended by the male line from the founder of the monarchy, shared, in common with the ruling monarch, the sacred name of Inca. They wore a peculiar dress, enjoyed special privileges, and lived at court; but none of them could enter the presence of the Inca except with bare feet, and bearing a burden on the shoulders, in token of allegiance and homage. They formed, however, the real strength of the empire, and, being superior to the other races in intellectual power, they were the fountain whence flowed that civilization and social organization which gave P. a position above every other state of South America. Prior to the arrival of the Spaniards, P. contained a population of 30,000,000—twelve times greater than it is at the present day. The empire was divided into four parts, into each of which one of the great roads branched from Cuzco. Each of the four provinces was administered by a viceroy or governor. The nation was further subdivided into departments of 10,000 inhabitants, each also administered by a governor; and there were other subdivisions into various numbers, the lowest of which was ten, and every one of which was ruled by head-men, who were responsible for offenders, and were required to see that those under them enjoyed the rights to which they were entitled. The governors and chief rulers were selected from the Inca aristocracy. The laws related almost wholly to criminal matters, and were few, and remarkably severe. Theft, adultery, murder, blasphemy against the Sun, and burning of bridges, were all capital crimes. The territory of the empire was divided into three portions, and from these portions were derived the revenue that supported the *Sun*, the *Inca*, and the *people* respectively.

The numerous priesthood, and the costly ceremonial of the national worship, were supported by the first; the royal household and the government expenditure were defrayed out of the second; and the people, at so much per head, divided the third of these portions. There was a new division of the soil every year, and the extent of land apportioned to each householder was regulated by the numbers in his family. It might be supposed that this arrangement would be fatal to improvement of the soil, and to the pride in and love of home; but this was not the case; and it is probable that at each partition of the soil, the tenant was, as a rule, confirmed in his occupation. The three divisions were cultivated by the people, the territory apportioned to the Sun being attended to first, that belonging to the people themselves next, and lastly, the division belonging to the Inca. The labor on the Inca's share of the land was engaged in by the whole population at the same time, and the work was lightened by the national songs and ballads, and the scene made picturesque by the holiday attire of the workers. The manufactures of the country were managed in the same way, the people laboring first in making clothes for themselves, and afterwards giving their work to the Inca. The mines were worked by the people, but no one gave more than a certain amount of time to the government service (during which time he was maintained at the government expense), and after discharging the stipulated amount of duty, he was succeeded by another. Money was unknown among the Peruvians. They were a nation of workers, but they wrought as the members of one family, labor being enforced on all for the benefit of all.

The national policy of the Peruvians had its imperfections and drawbacks, and though capable of unlimited extension, it was not capable of advancement. It was in the last degree conservative, and was of such a nature that the introduction of reform in any vital particular must have overturned the whole constitution. Nevertheless, the wants of the people were few, and these were satisfied. Their labor was not more than they could easily perform, and it was pleasantly diversified with frequent holidays and festivals. They lived contentedly and securely under a government strong enough to protect them; and a sufficiency of the necessities of life was obtained by every individual. Still, in the

valleys of the Cordilleras and on the plain of Cuzco, may be heard numberless songs, in which the Peruvian mourns the happy days of peace, security, and comfort, enjoyed by his ancestors. Further, they revered and loved their monarch, and considered it a pleasure to serve him. With subjects of such a temper and inclination, the Incas might direct the entire energies of the nation as they chose; and it is thus that they were able to construct those gigantic public works which would have been wonderful even had they been performed with the assistance of European machinery and appliances.

The Peruvian system of agriculture was brought to its highest perfection only by the prodigious labor of several centuries. Not only was the fertile soil cultivated with the utmost care, but the sandy wastes of the coast, unvisited by any rains, and but scantily watered by brooks, were rendered productive by means of an artificial system of irrigation, the most stupendous, perhaps, that the world has ever seen. Water was collected in lakes among the mountains, led down the slopes and through the sands of the coast, apparently doomed to sterility, by canals and subterranean passages constructed on a vast scale, and the ruins of which, to be seen at the present day, attest the industry, ingenuity, and admirable patience of the Peruvians.

The aqueducts, which were sometimes between 400 and 500 miles in length, were in some cases tunnelled through massive rocks, and carried across rivers and marshes. They were constructed of large slabs of freestone, fitting so closely as to require no cement, and answering perfectly the purpose for which they were intended, for the sandy wastes were converted into productive fields and rich pasture-lands, and the coast teemed with industrious inhabitants. In the valley of Santa, there were once 700,000 inhabitants; there are now only 12,000: in that of Anculama, there were 30,000 individuals; there are now only 425. The fields on the coast were also enriched with the manure of sea-fowls, which has since come to be known as guano. Fragments of the aqueducts still remain, and are surveyed with astonishment by the traveler, who wonders that such works could have been constructed by a people who appear to have employed no machinery, had no beasts of burden, who did not know the secret of the true arch, and who did not use tools or instruments of iron. But the triumphs of industry were not more decided on the coast than they were in the *Sierra*. Here, at elevations visited now only by the eagle and the condor, the rocky heights, riven by innumerable chasms and deeply-cut precipices, were crowned with waving crops of wheat and maize. Where the mountain-slopes were too steep to admit of cultivation, terraces were cut, soil was accumulated on them, and the level surfaces converted into a species of hanging-gardens. Large flocks of llamas were grazed on the plateaux; while the more hardy vicuñas and alpacas roamed the upper heights in freedom, to be driven together, however, at stated periods, to be shorn or killed. The wool yielded by these animals, and the cotton grown in the plains and valleys, were woven into fabrics equally remarkable for fineness of texture and brilliancy of color.

The character of the architecture of the Peruvians has already been alluded to. The edifices of Incarial times are oblong in shape and cyclopean in construction. The materials used were granite, porphyry, and other varieties of stone; but in the more rainless regions, sun-dried bricks were also much used. The walls were most frequently built of stones of irregular size, but cut with such accuracy, and fitting into each other so closely at the sides, that neither knife nor needle can be inserted in the seams. Though the buildings were not, as a rule, more than from 12 to 14 feet high, they were characterized by simplicity, symmetry, and solidity. The Peruvian architects did not indulge much in external decoration; but the interior of all the great edifices was extremely rich in ornament. In the royal palaces and temples, the most ordinary utensils were of silver and gold; the walls were thickly studded with plates and bosses of the same metals; and exquisite imitations of human and other figures, and also of plants, fashioned with perfect accuracy in gold and silver, were always seen in the houses of the great. Hidden among the metallic foliage, or creeping among the roots, were many brilliantly-colored birds, serpents, lizards, &c., made chiefly of precious stones; while in the gardens, interspersed among the natural plants and flowers, were imitations of them, in gold and silver, of such truth and beauty as to rival nature. The Temple of the Sun at Cuzco, called *Coricancha*, or 'Place of Gold,' was the most magnificent edifice in the empire. On the western wall, and opposite the eastern portal, was a splendid representation of the Sun, the god of the nation. It consisted of a human face in gold, with innumerable golden rays emanating from it in every direction; and when the early beams of the morning sun fell upon this brilliant golden disc, they were reflected from it as from a mirror, and again reflected throughout the whole temple by the numberless plates, cornices, bands, and images of gold, until the temple seemed to glow with a sunshine more intense than that of nature.

The religion of the Peruvians, in the later ages of the empire, was far in advance of that of most barbarous nations. They believed in a Great Spirit, the Creator of the universe, who, being a spirit, could not be represented by any image or symbol, nor be made to dwell in a temple made with hands. They also believed in the existence of the soul hereafter, and in the resurrection of the body. The after-life, they considered to be a condition of ease and tranquillity for the good, and of continual wearisome labor, extending over ages, for the wicked. But while they believed in the Creator of the world, they also believed in other deities, who were of some subordinate rank to the Great Spirit. Of these secondary gods, the Sun was the chief. They revered the Sun as the source of their royal dynasty; and everywhere throughout the land, altars smoked with offerings burned in his worship.

About the year 1516, and ten years before the death of Huayna Capac, the first white man had landed on the western shores of South America; but it was not till the year 1532, that Pizarro (q. v.), at the head of a small band of Spanish adventurers, actually invaded Peru. On his death-bed, the great Inca expressed a wish that the kingdom of Quito should pass to Atahualpa, one of his sons by a princess of Quito whom he had received among his concubines, and that all his other territories should fall to his son Huascar, the heir to the crown, and who, according to the custom of the Incas, should have inherited all his dependencies. Between these two princes, quarrels, resulting in war, arose; and when Pizarro entered P., he found the country occupied by two rival factions, a circumstance of which he took full advantage. Atahualpa had completely defeated the forces of his brother, had taken Huascar prisoner, and was now stationed at Caxamalca, on the eastern side of the Andes, whither, with a force of 177 men, of whom 27 were cavalry, the dauntless Spanish leader, in September 1532, set out to meet him. For the capture of Atahualpa by the Spaniards, his subsequent life and violent death, see article ATAHUALPA.

Shortly after the execution of the Inca at Caxamalca, the adventurers set out for Cuzco. Their strength had been recently increased by reinforcements, and they now numbered nearly 500 men, of whom about a third were cavalry. They entered the Peruvian capital, 15th November 1533, having in the course of their progress toward the city of the Incas, had many sharp, and sometimes serious encounters with the Indians, in all of which, however, their armor, artillery, and cavalry gave them the advantage. At Cuzco they obtained a vast amount of gold, the one object for which the conquest of P. was undertaken. As at Caxamalca, the articles of gold were for the most part melted down into ingots, and divided among the band. Their sudden wealth, however, did many of them little good, as it afforded them the means of gambling, and many of them, rich at night, found themselves again penniless adventurers in the morning. One cavalier having obtained the splendid golden image of the Sun as his share of the booty, lost it in play in a single night. After stripping the palaces and temples of their treasures, Pizarro placed Manco, a son of the great Huayna Capac, on the throne of the Incas. Leaving a garrison in the capital, he then marched west to the sea-coast, with the intention of building a town, from which he could the more easily repel invasion from without, and which should be the future capital of the kingdom.

Choosing the banks of the river Rimac, he founded, about six miles from its mouth, the *Ciudad de los Reyes*, 'City of the Kings.' Subsequently, its name was changed into Lima, the modified form of the name of the river on which it was placed. But the progress of a higher civilization thus begun, was interrupted by an event which overturned the plans of the general, and entailed the severest sufferings on many of his followers. The Inca Manco, insulted on every hand, and in the most contemptuous manner, by the proud Castilian soldiers, effected his escape, and headed a formidable rising of the natives. Gathering round Cuzco in immense numbers, the natives laid siege to the city, and set it on fire. An Indian force also invested Xauxa, and another detachment threatened Lima. The siege of Cuzco was maintained for five months, after which time the Peruvians were commanded by their Inca to retire to their farms, and cultivate the soil, that the country might be saved from famine. The advantages, many, though unimportant, which the Inca gained in the course of this siege, were his last triumphs. He afterwards retired to the mountains, where he was massacred by a party of Spaniards. More formidable, however, to Pizarro than any rising of the natives, was the quarrel between himself and Almagro, a soldier of generous disposition, but of fiery temper, who, after Pizarro, held the highest rank among the conquerors. For the insurrection, trial, and execution of this chief, see article ALMAGRO. The condition of the country was now in every sense deplorable. The natives, astonished not more by the appearance of cavalry than by the flash, the sound, and the deadly execution of artillery, had succumbed to forces which they had no means of successfully encountering.

Meantime, the Almagro faction had not died out with the death of its leader, and they still cherished schemes of vengeance against the Pizarros. It was resolved to assassinate the General as he returned from mass on Sunday, 26th June 1541. Hearing of the conspiracy, but attaching little importance to the information, Pizarro nevertheless deemed it prudent not to go to mass that day. His house was assaulted by the conspirators, who, murdering his servants, broke in upon the great leader, overwhelmed him by numbers, and killed him (see PIZARRO). The son of Almagro then proclaimed himself governor, but was soon defeated in battle, and put to death. In 1542, a council was called at Valladolid, at the instigation of the ecclesiastic Las Casas, who felt shocked and humiliated at the excesses committed on the natives. The result of this council was, that a code of laws was framed for P., according to one clause of which, the Indians who had been enslaved by the Spaniards were virtually declared free men. It was also enacted that the Indians were not to be forced to labor in unhealthy localities, and that in whatever cases they were desired to work in any particular locality, they were to be fairly paid. These and similar clauses enraged the adventurers. Blasco Nuñez Vela, sent from Spain to enforce the new laws, rendered himself unpopular, and was seized, and thrown into prison. He had come from Spain, accompanied by an 'audience' of four, who now undertook the government. Gonzalo Pizarro (the last in this country of the family of that name), who had been elected captain-general of P., now marched threateningly upon Lima. He was too powerful to withstand, and the audience received him in a friendly manner, and after the administration of oaths, elected him governor as well as captain-general of the country. The career of this adventurer was cut short by Pedro de la Gasca, who, invested with the powers of the sovereign, arrived from Spain, collected a large army, and pursued Pizarro, who was eventually taken and executed.

A series of petty quarrels, and the tiresome story of the substitution of one ruling functionary for another, make up a great part of the subsequent history. The country became one of the four viceroyalties of Spanish America, and the Spanish authority was fully established and administered by successive viceroys. The province of Quito was separated from P. in 1718; and in 1788, considerable territories in the south were detached, and formed into the government of Buenos Ayres. At the outbreak of the War of Independence in South America, the Spanish government, besides having much declined in internal strength, was distracted with the dissensions of a regency, and torn by a civil war; nevertheless, in 1820, the Spanish viceroy had an army of 23,000 men in Peru, and all the large towns were completely in the hands of Spanish officials. P. was the last of the Spanish South American possessions to set up the standard of independence. In August 1820, a rebel army, under General San Martín, one of the liberators of Chili, sailed for P., and after a number of successes both on sea and land, in which the patriots were most effectively assisted by English volunteers, the independence of the country was proclaimed 28th July 1821, and San Martín assumed the protectorate of the young republic. From this date to the year 1860, 21 rulers, under various titles, have held sway. For the first 24 years of its existence as an independent republic, the country was distracted and devastated by wars and revolutions. In 1845, Don Ramón Castilla was elected president; and under his firm and sagacious guidance, the country enjoyed an unwonted measure of peace, and became regularly organized. Commerce began to be developed, and important public works were undertaken. The term of his presidency ended in 1851, in which year General Rufino José Echenique was elected president. The country, however, was discontented, and Castilla again found himself, in 1855, at the head of affairs.

Slavery, which, although abolished by the charter of independence, still existed, was put an end to by a decree dated October 1854. In August 1863, a quarrel had taken place at the estate of Talambo, in the north, between some Basque emigrants and the natives, in which several of the disputants were killed or wounded. Taking advantage of this occurrence, the Spanish government sent out a 'special commissioner' in the spring of 1864, to complain of injuries sustained by Spaniards. The 'commissioner' left Lima on the 12th April, and on the 14th, a Spanish squadron, under Admiral Pinzon, took forcible possession of the Chincha Islands. The European consuls protested loudly against this outrage, and the Peruvians were greatly excited. War was, however, averted, President Pezet being unwilling to risk hostilities with Spain; and, in January 1865, a treaty of peace was signed. This did not lead, however, to internal peace. The president was declared a traitor by the Assembly in the same month that saw the treaty of peace ratified in the Spanish capital. General Canesco, after a severe struggle, assumed the presidential authority, and retained it till November, when Colonel Prado was nominated temporary dictator. The obnoxious treaty was now rejected, and P. entered, January 1866, into a treaty, offensive and defensive, with Chili (q. v.), which country was then at war with Spain;

but this led to no serious consequences to P., an unsuccessful attack on Callao having vindicated Spanish honor. In October, General Prado was regularly elected president, and, in February 1867, he recommended a new constitution, according to which there is a senate of 44 members and a house of 110 representatives. Prado had to resign in 1868; his successor, Balta, was assassinated in 1872; Prado, who was president till 1876, was succeeded by Prado. Under Prado the country had been peaceful and prosperous, and education had been greatly extended. In 1879 P., as the ally of Bolivia, became involved in war with Chili. The war was carried on desultorily in 1879 and 1880: Arica was besieged and taken; the most powerful Peruvian iron-clads were sunk or captured; finally, in 1881, Callao and Lima were taken and occupied by the Chilians. The victors imposed severe terms upon the vanquished; and this and the anarchical condition in which P. was left, long postponed the settlement of a definitive peace.

PERUGIA, a city of Central Italy, capital of the province of its own name, stands on a lofty elevation, 800 feet high, on the right bank of the Tiber, ten miles east of the lake of Perugia (ancient *Lacus Trasimenus*), and 84 miles north of Rome. It is surrounded with walls pierced with numerous gates, of which the *Arch of Augustus* (so called from the inscription *Augusta Perusia* over it, inscribed by Augustus) is the finest. It is the see of a bishop, and contains upwards of 45 churches, and many monastic establishments. Its streets are wide, and there are several squares lined with massive buildings. The broad Corso, which contains the finest edifices, unites two squares, one of which is occupied by the Duomo, or cathedral, dedicated to San Lorenzo, and dating from the end of the 15th century. It is in a fine bold Gothic style, and contains many excellent paintings, carvings, &c. Many of the churches and convents are noble Gothic structures, and all of them are more or less famous for their pictures, some of which are by Raphael, Perugino, and other great masters. In the vicinity of the city, a number of tombs, supposed to mark the site of the necropolis of ancient P., were discovered in 1840. The tombs contain numerous beautiful *cinerary urns*, in marble and travertine; and lamps, vases, bronze armor, ornaments, pateræ, &c., were also found, but have for the most part been removed to a neighboring villa. The university of P., founded in 1320, is not one of the 17 state universities, but is supported by the province. It has various museums, and a library of 80,000 vols., with some valuable manuscripts. The attendance is not numerous. Besides the picture-gallery of the Academy of Fine Arts, there are numerous private art-collections. P. contains also many interesting palaces, a beautiful fountain, an exchange, theaters, &c. Velvets, silk-stuffs, woollen goods, soap, brandy, and liquors are manufactured; and a considerable trade is carried on in corn, oil, wool, wine, and cattle. Pop. (1881) 17,395.

P., the ancient *Perusia*, was one of the twelve Etrurian republics. It became tributary to Rome 294 B.C. During the war between Mark Antony and Augustus, it was taken by the latter, and was burned down. It was captured by the Goths under Totila at the fall of the Western Empire. Under Pope Paul III., it was united to the Papal States. In 1860, it became a part of the Kingdom of Italy under Victor Emmanuel.

PERUGIA, LAKE OF. See *TRASIMENUS LACUS*.

PERUGINO, a celebrated Italian painter, whose real name was PIETRO VANNUCCI, was born at Citta della Pieve in Umbria, about 1446, but having afterwards established himself in the neighboring and more important city of Perugia, where he had the right of citizenship, he is commonly called Il Perugino. It is generally thought that he studied under Andrea Verocchio at Florence. He executed numerous excellent works in various cities, particularly in Florence, Siena, Pavia, Naples, Bologna, Rome, and Perugia. Sixtus IV. employed him in the Cappella Sistina; and his fresco of 'Christ giving the Keys to Peter' is by far the best of those painted on the side-walls of that chapel. He also, along with other contemporary painters, decorated the Stanze of the Vatican; and his works there are the only frescoes that were spared when Raphael was commissioned to substitute his works for those formerly painted on the walls and ceilings. The fact of his having had Raphael for his pupil, has no doubt in one way increased the reputation of P., but it has also in some degree tended to lessen it, as, in many of P.'s best productions, the work of Raphael is confidently pointed out by connoisseurs, and, indeed, many important pictures, at one time acknowledged as his, are now ascribed to his great pupil. His high standing as a painter, however, is established by many admirable works, in which no hand superior to his own could have operated; and, with the exception, perhaps, of Francia, who in some respects is esteemed his equal, he is now acknowledged as the ablest of the masters of that section of the early Italian school in which religious feeling is expressed with great tenderness, in pictures remarkable for delicate execution.

P.'s works are also distinguished by rich and warm coloring.

An excellent example of this master's work may be studied in the collection of the National Gallery, London—'No. 288. The Virgin Adoring the Infant Christ.' P.'s reputation was high, when the introduction of the cinquecento style, by Leonardo and Michael Angelo, tended to throw into the shade the art of the earlier masters. Disputes ran high between the leaders of the old and new styles, and Michael Angelo is said to have spoken contemptuously of P.'s powers. This, of course, has biased Vasari's opinion in his estimate of the opponent of his idol, but P.'s reputation now stands very high, and his works are greatly esteemed. Raphael was about twelve years of age when he was entered as a pupil with P., who was then (1495) engaged on the frescoes in the Sala del Cambio (the Exchange) at Perugia. P. died at Castello di Fontignano, near Perugia, in 1524.

PERUVIAN ARCHITECTURE. Although the buildings of Peru were erected probably about the 12th c. A.D., they possess an extraordinary likeness to those of the Pelagii in Europe. This resemblance in style must be accidental, arising probably from the circumstance, that both nations used bronze tools, and were unacquainted with iron. The Peruvian walls are built with large polygonal blocks of stone, exactly like what we call 'Cyclopean masonry.' The jambs of the doorways slope inwards, like those of Etruscan tombs, and have similar lintels. The walls of Cuzco are good examples of this style. It is further remarkable, that these walls are built with re-entering angles, like the fortifications which were adopted in Europe only after the invention of gunpowder.

PERUVIAN BARK. See CINCHONA. An important instance of commercial enterprise, directed to providing relief for human suffering, has been the introduction of cinchonas, or Peruvian Bark trees into British India. This had long been urged on the East India Company by Dr. Royle, but was not undertaken till after his death. The same thing had been attempted a year or two before by the Dutch in Java, on the urgent representations of the botanist Blume, but with very imperfect success, owing to their having procured chiefly plants of a species which produces bark of very inferior quality, and yields little quinine. But Mr. Markham, who was sent to South America by the East India Company to procure seeds and plants, was successful in introducing into British India, in the latter part of 1861, a number of the very best species, which were planted chiefly on the Neilgherry Hills, and partly also on the mountains of Ceylon and the Himalaya, and from these stations have been diffused throughout the Madras Presidency. There are now about 2,700,000 cinchona trees on the government plantations, and the harvest for 1875 amounted to 65,200 lbs., worth about £6700. The whole yield of the Madras Presidency is about double that, 204,000 lbs. having been brought into the London market in 1877-8. Thus an abundant supply of Peruvian bark, and consequently of quinine, has been secured at a moderate price, and yet with profit to the cultivator. In procuring the young trees and seeds which he conveyed to India, Mr. Markham experienced great difficulty from the jealousy of the South American governments, anxious to maintain a rigid monopoly in this precious commodity, and yet taking no effectual means to prevent the rapidly-extending waste of the trees in their native forests. Mr. Markham in all his travels saw only one Peruvian Bark tree which had been planted by the hand of man. (See Markham's *Travels in Peru and India*, 1862.)

PERUVIAN GOOSEBERRY. See *PHYSLIS*.

PERUWELS, a town of Belgium, in the province of Hainaut, with breweries, limekilns, and some linen manufactures. Pop. 8000.

PESA'RO (the ancient *Pisaurum*), a town of Central Italy, in the province of Pesaro and Urbino, on a rocky wooded hill, on the right bank of the Foglia, and one mile from the mouth of that river in the Adriatic—20 miles north-east of Urbino. Its streets are broad, and it is surrounded by walls and defended by a citadel. It is a bishop's seat, and contains a cathedral and other churches. The country in the vicinity is fruitful and beautiful; the figs of the district being esteemed the best in Italy. The port cannot now accommodate vessels of more than 70 tons burden; but is large enough to contain 200 vessels of light draught. Silks, pottery, glass, and leather are manufactured; and an active trade in silk, hemp, and woollen goods is carried on. Pop. 11,400.

PESCHIERA, a frontier town and fortress of the kingdom of Italy, and a member of the famous Quadrilateral (q. v.), stands partly on an island in the channel of the Mincio, and partly on the right bank of that river, at its outlet from the Lake of Garda. The town itself is a poor place of less than 2000 inhabitants. P. commands the right bank of the river, and in connection with it is the extensive work called the 'Salvi,' which covers the approaches of the river in that direction. During the French republican war, P. was a simple pentagon. Its fortifications, however, were greatly strengthened by the Austrians. It is defended by walls and by forts, lunettes, fosses, and a covered-way; and

the purpose which it is mainly intended to serve, besides that of forming an entrenched camp capable of accommodating a considerable number of troops, is to harass an army attempting to cross the Mincio by Goito or Valeggio. In the island portion of the town are extensive barracks, forming three sides of a square. P. is a station on the Milan and Venice Railway, and is also a station of the Austrian government steamers that ply on the Lake of Garda. P. was taken by the Piedmontese under King Charles Albert in 1848, and was again invested by them in June 1859, after the battle of Solferino. The conclusion of the treaty of Villafranca, however (July 11, 1859), relieved P. from a siege.

PESHAW'ER, or PESHAWUR, an important town, near the N.W. 'scientific' frontier of India, capital of a province of the same name, 18 miles east of the eastern extremity of Khyber Pass, and 150 miles E.S.E. of Cabul. It is defended by a bastioned wall, and commanded by a fort, the fear of which prevents internal disturbances. At the commencement of the present century, P. had 100,000 inhabitants. Under the stern rule of the Sikhs, however, its trade languished, and its splendid mosques, many of them in the richest style of oriental architecture, fell into decay. It is on the route from Hindustan to Cabul and Khorassan by the Khyber Pass, and is the seat of a British garrison, maintained here for the purpose of preserving the security of the route. Under British protection, the town has revived, trade has become more active, and the appearance of the suburbs and environs is improved. Pop. (1881) 79,982. The district of P., included in the Punjab, and formerly forming a portion of Afghanistan, is 1929 square miles in extent, and has 523,152 inhabitants. It is exceedingly fruitful. The *division* of P., which includes the district of P. and two others, has an area of 7767 miles, and a population of 1,085,785.

PESHIT'Ō, or rather PESHIT'Ō (Syr., not, as generally supposed, 'simple,' 'faithful,' scil. Version, but the 'explained,' i. e., translated, Bible), is the name given to the authorized Syriac Version of the Old, and the greatest part of the New Testament. This version holds among the Syrian Christians the same place as the Vulgate in the Roman, and the 'Authorized Version' in the English Church. Many are the traditions about its origin. Thus, the translation of the Old Testament is supposed to date from the time of Solomon and Hiram; or to have been done by Asa, the priest; or, again, that it belongs to the time of the Apostle Thaddæus (Adæus), and Abgar, the king of Osroene, in the 1st c. after Christ. To the same period is also supposed to belong the translation of the New Testament, which is ascribed to Achaëus, a disciple of Thaddæus, the first Edessian bishop and martyr. Recent investigation has not as yet come to any nearer result than to place the latter vaguely in the 2d, and the former in the 3d c., and to make Judaic-Christians the authors of both. Ephraem Syrus (q. v.), who wrote in the 4th c., certainly speaks of the P. as *Our Version*, and finds it already necessary to explain some of its terms, which had become obsolete. Five books of the New Testament (the Apocalypse and four of the Epistles) are wanting in all the MSS., having probably not yet formed part of the canon when the translation was made. The version of the Old Testament was made direct from the Hebrew, and by men imbued with the Palestinian mode of explanation. It is extremely faithful, and astonishingly free from any of those paraphrastic tendencies which pervade more or less all the Targums or Aramaic versions. Its renderings are mostly very happy, and coincide in many places with those of the Septuagint, a circumstance which has given rise to the erroneous supposition, that the latter itself had been drawn upon. Its use for the Old Testament is more of an exegetical, for the New Testament, more of a critical, nature. Anything like an edition of the P. worthy of its name, is still as much a desideratum as is a critical edition of the Septuagint or the Targums, and consequently investigators have as yet been unable to come to anything but very hazy conclusions respecting some very important questions connected with it.

The *edito princeps* of the New Testament part dates Vienna 1555, that of the Old Testament is contained in the Paris Polyglot of 1645. Several portions of the P. have been translated again into Arabic. The Syriac translation of those parts of the New Testament which are not to be found in the P., but are now incorporated into our Syriac Bibles, are of late and uncertain date.

PESTALOZZI, JOHANN-HEINRICH, was born at Zürich, 12th January 1745. His family belonged to the middle-class gentry. He was destined for the Christian ministry, but turned aside, however, from this profession, and betook himself to the study of law. To this pursuit he did not long remain constant. The perusal of Rousseau's *Emile*, and the unsatisfactory political condition in which he found Europe, united to disgust him with the artificial life of cities, and he accordingly removed to the country, to devote his life to farming. Purchasing some waste land (after he had acquired the necessary experience), he applied himself successfully to its cultivation, marrying about the same time the daughter of a wealthy merchant. His mind continuing to be

afflicted by the contemplation of the unhappy condition of the masses of the people, he devoted himself, during the intervals of his work, to the consideration of the means best suited to promote their elevation. He was convinced that, by means of a sound education, a remedy might be found for the many evils by which he was surrounded, and by which society was infected.

To give effect to his theories, he converted his own house into an orphan asylum, and endeavored, by a judicious blending of industrial, intellectual, and moral training, to afford a specimen of sound education, and one so contrived as to be practicable as a national scheme. Meanwhile, the pursuit of his benevolent enterprises involved him, after the lapse of fifteen years (1775—1790), in bankruptcy. The failure of his plans, and the democratic tendency of his opinions, brought upon him a good deal of contempt and opposition. His only consolation was having saved from degradation and neglect upwards of 100 children, and having issued several volumes on education, containing the results of his experience, and his hopes for the future of the masses. Many subsequent attempts to found schools and to give a specimen of rational scholastic training, were made by P., with varying educational success, but with invariable pecuniary embarrassment. His writings, meanwhile, increased in number and importance. The great idea which lay at the basis of his method of intellectual instruction was, that nothing should be treated of except in a concrete way. *Objects themselves* became in his hands the subject of lessons tending to the development of the observing and reasoning powers—not lessons about objects. In arithmetic, he began with the concrete, and proceeded to the abstract; and into the teaching of writing, he for the first time introduced graduation. His special attention, however, was directed to the moral and religious *training* of children, as distinct from their mere *instruction*; and here, too, graduation and a regard to the nature and susceptibilities of children, were conspicuous features of his system. Almost all P.'s methods are now substantially adopted by the instructors of elementary teachers in the Normal Schools of Europe, and to no man perhaps has primary instruction been so largely indebted. He died in 1827 at Brugg, in the canton of Basel, overwhelmed with mortifications and disappointments.

PESTH, the most populous and important commercial city of Hungary, on the left bank of the Danube, opposite Buda (q. v.), and 171 miles east-south-east of Vienna by railway. It occupies a low and level site, and contrasts strongly with the antique, picturesque, and rock-built Buda, on the other side of the river. The two cities are connected by a magnificent suspension-bridge, erected in 1849, and which spans a water-way of about 1500 feet. The official name of the united cities is, since 1872, compounded of the two, in the form *Budapest*. Along the P. side of the river runs a wide quay, paved and terraced, and backed by a handsome row of buildings, 1½ mile long. The city consists of five divisions—the Inner, Leopold, Theresa, Joseph, and Francis towns. The Inner town, on the bank of the Danube, is the oldest, and the other divisions surround it in the form of a semicircle. P. is the seat of the chief judicial courts of Hungary. Its university, founded at Tyrnau, was transferred to Buda in 1780, and thence was removed hither in 1784. It is richly endowed, and is attended by upwards of 2000 students, while the professors and other teachers number 140. Attached to it are a museum, a botanic garden, an observatory, and a library containing over 100,000 volumes, with 1600 MSS. besides. A handsome new chemical laboratory was opened in 1872; and in the same year a decree was passed that a new military academy should be opened, of which the teaching staff counts 24. Of the chief buildings and institutions, the principal are the synagogue, a large and beautiful structure, completed in 1857; the New Buildings (*Neugebäude*)—an immense edifice, now used as barracks and as an artillery dépôt; the gymnasium; military school; academy of arts; national museum, with a library of 200,000 volumes, and valuable collections of coins, medals, and antiquities; veterinary school; the national and other theaters; and the Hungarian scientific society.

The town contains several important silk-spinning factories, and the principal articles of manufacture are silk, cotton, leather, jewelry, and musical instruments. The distilling of brandy, and the grinding of grain into meal and flour, are among the most important branches of industry. Four great fairs take place here annually, which draw together a concourse of more than 80,000 strangers, and at which exchanges, amounting in value to upwards of 32,000,000 florins, are made. The trade is chiefly in wines, raw hides, honey, wax, and an inferior spirit made from plums. After Vienna, P. has the greatest trade of any city on the Danube. Pop. of Budapest, (1880) 360,551.

P. is mentioned for the first time in the 12th c.; but although one of the oldest towns in Hungary, its importance dates only from the reigns of Maria Theresa and Joseph II. It was desolated by the Mongols in the 13th c., and after the battle of Mohács (q. v.) it fell into the hands of the Turks, who held it till 1686. At the beginning of the 18th c., it was an inconsiderable town,

and has only risen to importance within the last 150 years. It has suffered much from inundations of the Danube on several occasions, on one of which, in 1898, 2250 houses were destroyed. In May 1849, while Görgei, with an army of 40,000 Hungarians, occupied the heights above Buda, and bombarded the fortress, which was held for the imperial government by General Hentzi, the latter general retaliated by bombarding P.; but on the night of the 20th May, the Hungarians stormed and took the fortress; and on the following morning, raised above its battlements the standard of revolt. On the field of Rákos, in the vicinity, where the great national assemblies of the Magyars used to be held, horse-races, on the English model, now take place annually.

PESTILENCE. The terms Plague and Pestilence, corresponding to the Greek *Loimos* and the Latin *Pestis*, have, until recent times, been used indiscriminately to denote any diseases of an epidemic character which affected large masses of the community, and were remarkable for their fatality, such as the oriental plague, the sweating sickness, cholera, certain virulent forms of fever, &c. 'Thus,' says Dr. Craigie, in his learned work on *The Practice of Physic* (vol. i. p. 349), 'the term *Loimos* was applied by the Greeks to designate a species of epidemic remittent fever; and the plague of Athens described by Thucydides is manifestly an epidemic form of the same disease, which has been at all times in the summer season endemic on the coasts and islands of the Mediterranean and Archipelago. The instances of *Loimos*, so frequently mentioned by Dionysius of Halicarnassus, and of *Pestis*, so often mentioned by Livy and other Roman historians in the early history of Rome, are manifestly the remittent or remittent-continuous fever, which has been at all times the native product of that district, and which acquired, after inundations of the Tiber, or a certain train of weather, the characters of a very generally diffused, a very malignant, and a very mortal distemper. Numerous instances of a similar inaccurate mode of expression occur in designating the remittent fevers of the middle ages and of modern times; and we find, even in the early history of the colonization of the West Indian Islands and the United States, frequent examples of the term plague being applied to the remittent fever of these regions, and especially to epidemic attacks of yellow fever.' During the middle ages, we find the term *Pestis* applied to numerous disorders, such as syphilis, small-pox, erysipelas, epidemic sore throat, petechial fever, the sweating sickness, gangrenous pneumonia, ergotism, &c.

Several Hebrew words are translated *pestilence* or *plague*, in the authorized version of the Old Testament. Some of these pestilences were sent as special judgments, and are beyond the reach of inquiry; others have the characteristics of modern epidemics, in so far as their action was not unnaturally rapid, and they were general in their attacks. Sufficient data are not in our possession to enable us to identify with certainty any of these epidemics. It has been supposed by some critics that in some of these cases (as in Deuteronomy, xxviii. 27; Amos, iv. 10; and Zachariah, xiv. 13; and in the case of Hezekiah) the oriental plague is referred to; but Mr. Poole (Smith's *Dictionary of the Bible*, vol. ii. p. 883) is of opinion that there is not any distinct notice of this disease in the Bible.

PE'STO. See PAESTUM.

PE'TAL. See COROLLA.

PETA'RD, an instrument for blowing open gates, demolishing palisades, &c. It consists of a half-cone of thick iron filled with powder and ball; this is firmly fastened to a plank, and the latter is provided with hooks, to allow of its being attached securely to a gate, &c. The engineers attached the petard, lighted the slow-match by which it was to be fired, and fled. When the explosion took effect, a supporting column charged through the breach, while the defenders were yet in consternation. The petard has been almost universally superseded by the use of powder-bags. Large petards contained as much as 13 lbs. of powder.

PE'TCHARY, the popular name of a number of species of the genus *Tyrannus*, sometimes ranked with the Shrikes (*Laniada*), and sometimes with the Fly-catchers (*Muscicapida*). The name seems to be derived from the cry of the GRAY P. (*T. dominicensis*), a bird very common in the warm parts of America and in some of the islands of the West Indies, gregarious and migratory, spending the spring and summer in the islands, and retiring to the hottest parts of the mainland from the end of September to the beginning of January. Its cry is a kind of shriek, consisting of three or four shrill notes, incessantly repeated. The entire length of the Gray P. is about 9½ inches. It is a very bold and strong bird, and in defence of its young, will maintain the battle against any hawk. It feeds partly on insects, sometimes on humming-birds, and partly on berries. When fat, it is much esteemed for the table, and great numbers are shot on this account.—The COMMON P. (*T. caudifasciatus*) is one of the most common birds of the West Indies. At certain seasons of the year, when very fat, it is in great request for the table. This bird has been observed to play with

a large beetle, as a cat does with a mouse, letting it drop, and catching it before it can reach the ground. It is a very bold bird, and does not scruple to attack a dog passing near its nest.

PETCHO'RA, a large river in the north of European Russia, rises on the western slope of the Ural Mountains, flows north through the eastern parts of the governments of Vologda and Archangel to about 66° 25' N., then south-east for about 150 miles, and finally sweeping toward the north, and expanding into an estuary 80 miles wide and full of islands, falls into the Arctic Ocean, after a course of 940 miles. It is said to be navigable for large river-boats for upwards of 700 miles. The estuary, which is open from the middle of June till the middle of September, has a depth of from 20 to 30 feet. The country through which this river flows is still quite uncultivated; dense forests extend on both sides, and the character of the scenery is wild, sombre, and melancholy. The forests abound in larchwood, now largely used in the construction of iron-clad vessels. Within recent years, a colony has settled at the mouth of the P., for the purpose of felling, dressing, and exporting timber. See Seebolin's *Siberia in Europe* (1881).

PETE'CHILÆ. This term is given to spots of a dusky crimson or purple color, quite flat, with a well-defined margin, and unaffected by pressure, which closely resemble flea-bites. These spots result from a minute extravasation of blood beneath the cuticle. They occur most frequently on the back, at the bend of the elbow, and in the groin. They indicate an altered state of the blood, and are often symptoms of very serious diseases, as of typhus fever, plague, scurvy, &c. They likewise occur in very severe cases of small-pox, measles, and scarlet fever, when their presence must be regarded as indicative of extreme danger.

PETER, Str., apostle, named originally SIMON, was a native of Bethsaida, on the Lake of Gennesaret. His father was called Jonas; and the name by which P. is known in Christian history was given to him by our Lord, who changed his name of origin (Bar-Jona) into *Cephas*, a Syro-Chaldaic word, which means 'rock' or stone, and for which *Petra*, or, in the masculine form, *Petros*, is the Greek equivalent. He was a fisherman by occupation, and, together with his brother Andrew, was actually engaged in this occupation on the Sea of Galilee when our Lord called both to be his disciples, promising to 'make them fishers of men.' For this invitation they had been prepared by the preaching of John the Baptist, and they accepted it without hesitation. For the incidents recorded of P.'s life as a disciple, we must refer to the gospel narrative. These incidents all chiefly evince a warm and impulsive character, even down to the hour of weakness in which he denied his Master. It is plain from the gospel narrative that he was regarded by our Lord with special favor and affection, and the events which followed the ascension of our Lord fall in with this inference from that narrative. He was the first mover of the election of a new apostle in the room of Judas Iscariot; he was the spokesman of the rest on the day of Pentecost; he it was who answered to the charges when they were brought before the council; he is the chief actor in the tragic scene of the death of Ananias and Sapphira; he was the first to break down the wall of the prejudice of race by receiving a Gentile convert into the church; he was the first to propound in the council of Jerusalem the question to be discussed as to the obligation of the Mosaic observances.

The last incident of P.'s life supplied by the Scripture narrative is his presence in the council of Jerusalem, 49 A.D. Of his subsequent career, our only knowledge is derived from tradition. His special mission was to the Hebrew race, as Paul's to the Gentile; and he is supposed to have preached through Pontus, Galatia, Cappadocia, Asia, and Bithynia, chiefly to those of his own nation dispersed in these countries, all which are named in the address of the first of the two Epistles which he has left. Another tradition which, until the 16th c., met general acceptance, reports that he preached at Rome, that he took up his residence there as bishop, and that he there suffered martyrdom. This tradition is the main foundation of the Roman claim to supremacy in the church. It early encountered the opposition of the reformers; its first antagonist being a writer named Velerius, whose work was published in 1520, and who was followed by Flacius, Salamastus, and, above all, Spanheim. This view has found supporters in Baur and the Tübingen School; but the main current of scholarship, Protestant as well as Catholic—from Scaliger, Casaubon, Usher, Pearson, Cave, &c., down to Neander, Gieseler, Bertholdt, Olshausen, and others in our own country—has accepted the Roman tradition without hesitation. The time of his going to Rome has also been the subject of much discussion. By some, he is alleged not to have gone to Rome till the year 63, or, at all events, a short time before his martyrdom; others date his first visit as early as 42 or 43, without, however, supposing his residence after this date to have been continuous. In his first Epistle, it is implied that at the time of writing it he was at Babylon; and the name Babylon is by many critics held to be employed as a mystic designation of Rome, in accordance with a practice not

unusual with the Hebrews and other orientals; but there is nothing to fix very conclusively the date of this Epistle.

He is held by Roman Catholic writers to have fixed his see at Antioch before his coming to Rome; but of this supposed event also, the date is uncertain. His martyrdom is fixed in, with much probability, the year 66, and is supposed to have been at the same time and place with that of St. Paul. P. was sentenced to be crucified, and according to the tradition (preserved by Eusebius from Origen), prayed that he might be crucified with his head downwards, in order that his death might exceed in ignominy that of his Divine Master.

PETER, EPISTLES GENERAL OF, the name given to two Epistles contained in the canon of the New Testament. They are called *general*, because they are not addressed to particular churches or persons, like those of St. Paul; but (as in the case of the 1st Epistle) to all the Christians scattered throughout Asia Minor, or (as in the case of the 2d) to the entire body of Christians without exception. The objects of the 1st Epistle are to strengthen believers under trials;—to exhort them to the earnest performance of all duties—personal, social, and domestic; and to demonstrate how thoroughly that performance depends on a spiritual recognition of Christ and his work. There is a strong eschatological tendency in the Epistle; the apostle seems to grow more intensely serious, under the conviction that 'the end of all things is at hand' (chap. iv. 7). That the Epistle is the composition of Peter is very generally admitted. The external evidence is singularly strong; while the internal, derived from a consideration of style, sentiment, and doctrine, is equally so. We see in every sentence the ardent, impassioned, practical, unspeculative character of Peter, who held with a fine Hebraic vehemence of faith the great facts and principles of Christianity, but could not like the more subtle and logical Paul, give them a systematic representation. Many critics have warmly praised the beauty and strength of the language.—The *Second Epistle* stands in a very different position from the first. So far as external authority is concerned, it has hardly any.

The most critical and competent of the Fathers were suspicious of its authenticity; it was rarely if ever quoted, and was not formally admitted into the canon till the Council of Hippo, 393 A.D. The internal evidence is just as unsatisfactory. The great difference of style between it and the 1st Epistle is universally admitted. Bunsen, Ullmann, and Lange hold indeed that the second chapter is an interpolation, but consider the first and third genuine. Many of the ablest critics, however, regard the whole Epistle as a fabrication, and believe that its contents prove it was meant as an attack on the Gnosticism of the 2d century. [See the remarks on the Second Epistle of Peter in Neander's *Geschichte der Pflanzung und Leitung der Kirche durch die Apostel*.] The principal arguments adduced for maintaining its apostolic character are—1, that its rejection would endanger the authority of the canon; 2, that it is inexplicable how the church should have received it if it had not thought that Peter was the author.

PETERHOF, a palace of the emperor of Russia, on the southern shore of the Gulf of Finland, 15 miles west of St. Petersburg. The palace was built by Peter the Great in 1711, contains a fine collection of paintings, and is surrounded by a beautiful park. The town of P. has 15,000 inhabitants.

PETER LOMBARD. See **LOMBARD, PETER**.

PETER-PENCE, the name given to a tribute which was collected in several of the western kingdoms, and offered to the Roman pontiff, in reverence to the memory of St. Peter, whose successor that bishop is believed by Catholics to be. From an early period, the Roman see had been richly endowed; and although its first endowments were chiefly local, yet as early as the days of Gregory the Great, large estates were held by the Roman bishops in Campania, in Calabria, and even in the island of Sicily. The first idea, however, of an annual tribute appears to have come from England. It is ascribed by some to Ina (721 A.D.), king of the West Saxons, who went as a pilgrim to Rome, and there founded a hospice for Anglo-Saxon pilgrims, to be maintained by an annual contribution from England; by others, to Offa and Ethelwulf, at least in the sense of their having extended it to the entire of the Saxon territory. But this seems very uncertain; and although the usage was certainly anterior to the Norman conquest, Dr. Lingard is disposed not to place it higher than the time of Alfred. The tribute consisted in the payment of a silver penny by every family possessing land or cattle of the yearly value of 30 pence, and it was collected during the five weeks between St. Peter's and St. Paul's Day and August 1. In the time of King John, the total annual payment was £199, 8s., contributed by the several dioceses, in various proportions, which will be found in Lingard's *History of England*, vol. ii. p. 330. The tax, called *Romescoat*, with some variation, continued to be paid till the reign of Henry VIII., when it was abolished. By Gregory VII., it was sought to establish it for France; and it appears also in Denmark, Sweden, Norway, and Poland. This tribute differs from the pay-

ments of the feudatory kingdoms, such as Naples, Aragon, and England under the reign of John.

The pope having suffered a considerable diminution of his own revenue since the revolution of 1848, an effort has been made in several parts of Europe to revive this tribute. In some countries, it has been very successful, and the proceeds have been among the chief of the resources by which Pius IX. was so long enabled to meet the pressure of pecuniary embarrassments caused by his diminished territorial possessions. Since the total annexation of the Papal States to the kingdom of Italy, the tribute has been largely increased in France, Belgium, England, and Ireland.

PETER THE HERMIT, the first mover of the great medieval drama of the **CRUSADES** (q. v.), was of gentle birth, and a native of Amiens, where he was born about the middle of the 11th century. Having been educated at Paris, and afterwards in Italy, he became a soldier. After serving in Flanders without much distinction, he retired from the army, married, and had several children; but on the death of his wife, he became a monk, and ultimately a hermit. In a pilgrimage to the Holy Land about 1093, he was moved by seeing the Holy Sepulchre in the hands of the Infidel, and by the oppressed condition of the Christian residents or pilgrims; and on his return, spoke so earnestly to Pope Urban II., that he adopted his views, and commissioned him to preach throughout the West an armed confederation of Christians for the deliverance of the Holy City. (Hagenmeyer in his monograph *Peter der Eremita*, 1880, denies that P. was ever in Palestine till he went with the crusaders, and asserts that the scheme of a crusade originated with the pope, not with the hermit.)

Though P. was mean in figure, his enthusiasm lent him power. From province to province, from city to city he wandered. 'He rode,' writes Milman, 'on a mule, with a crucifix in his hand, his head and feet bare; his dress was a long robe, girt with a cord, and a hermit's cloak of the coarsest stuff. He preached in the pulpits, on the roads, in the market-places. His eloquence was that which stirs the heart of the people, for it came from his own—brief, figurative, full of bold apostrophes; it was mingled with his own tears, with his own groans; he beat his breast: the contagion spread throughout his audience. His preaching appealed to every passion—to valor and shame, to indignation and pity, to the pride of the warrior, to the compassion of the man, the religion of the Christian, to the love of the brethren, to the hatred of the unbeliever aggravated by his insulting tyranny, to reverence for the Redeemer and the saints, to the desire of expiating sin, to the hope of eternal life. The results are well known, as among those moral marvels of enthusiasm of which history presents occasional examples. All France, especially, was stirred from its very depths; and just at the time when the enthusiasm of that country had been already kindled to its full fervor, it received a sacredness and an authority from the decree of a council held at Clermont, in which Urban himself was present, and in which his celebrated harangue was but the signal for the outpouring, through all Western Christendom, of the same chivalrous emotions by which France had been borne away under the rude eloquence of the Hermit. For the details of the expedition, we must refer to the article **CRUSADES**; our sole present concern being with the personal history of Peter. Of the enormous but undisciplined army which assembled from all parts of Europe, one portion was committed to his conduct; the other being under the command of a far more skillful leader, Walter the Pennyless. P. placed himself at their head, mounted upon his ass, with his coarse woollen mantle and his rude sandals.

On the march through Hungary, they became involved in hostilities with the Hungarians, and suffered a severe defeat at Semlin, whence they proceeded with much difficulty to Constantinople. There the Emperor Alexis, filled with dismay at the want of discipline which they exhibited, was but too happy to give them supplies for their onward march; and near Nice, they encountered the army of the Sultan Solymán, from whom they suffered a terrible defeat. P. accompanied the subsequent expedition under Godfrey; but worn out by the delays and difficulties of the siege of Antioch, he was about to withdraw from the expedition, and was only retained in it by the influence of the other leaders, who foresaw the worst results from his departure. Accordingly, he had a share, although not marked by any signal distinction, in the siege and capture of the Holy City in 1099, and the closing incident of his history as a crusader was an address to the victorious army delivered on the Mount of Olives. He returned to Europe, and founded a monastery at Huy, in the diocese of Liege. In this monastery, he died, July 7, 1115.

PETER (DON PEDRO) THE CRUEL, King of Castile, and Leon, was the son of Alfonso XI. and Maria of Portugal, and was born at Burgos, 30th August 1334. On his father's death (1350), P. succeeded to the throne without opposition, but left the whole exercise of power to his mother, Donna Maria, and Albuquerque, his father's prime minister and chancellor. But by the instigation of his mistress (afterwards his queen), Marie de

Padilla, P. emancipated himself (1533) from the guidance of the queen-mother and her coadjutor Albuquerque, taking the reins of government in his own hands. His rule being much more impartial than that of the regency, obtained exceeding popularity, which was increased by his affable manner towards the mass of his subjects; but the strict justice with which he decided all causes between the rich and poor, the clergy and the laity, combined with a haughty and imperious carriage towards them, alienated from him the nobles and clergy.

The plottings of Albuquerque, who had fled to Portugal, having culminated (1554) in an outbreak in the province of Estremadura, P. marched against the rebels, but was betrayed by his brother, Henry of Trastamare, and taken prisoner (December 1554). Popular opinion now declared loudly in his favor; and having escaped from prison, he found himself speedily at the head of a powerful army, with which, despite the excommunication of the pope, he speedily reduced his opponents to submission. But this episode in his career had a disastrous influence on his character for the rest of his life. Betrayed by his relatives, and even by his mother, he became suspicious of every one; and having experienced to the full the power of his enemies, he scrupled not as to the weapons to be employed against them. The rest of his reign was devoted to the destruction of the power of the great vassals, the establishment of his own authority on the ruins of their feudal tyranny, and long continued and bloody wars with the kingdoms of Aragon and Granada. As the people, however, were in general well and justly governed, it is not improbable that he might have retained his throne in spite of his numerous enemies, had not the heavy taxes which were imposed to maintain the cost of his long wars with Aragon and Granada dissipated his popularity. Henry, who had fled to France, now seizing the favorable opportunity, returned (1566) at the head of a body of exiles, backed by Bertrand du Guesclin (q. v.) with an army of mercenaries, and aided by Aragon, France, and the pope. P., however, by promising to England the sea-board of Biscay, with the provinces of Guipuzcoa and Logrono, and supplying a contribution of 56,000 florins, prevailed upon Edward the Black Prince to espouse his cause.

Edward invaded Castile in the spring of 1567, totally defeated Henry and Du Guesclin at Navarette (April), taking the latter prisoner, releasing him almost immediately after, and speedily restoring P. to the throne. But the king disgusted his chivalrous ally by his cruelty to the vanquished, and paid no heed to his remonstrances; Edward accordingly repassed the Pyrenees, and left the misguided monarch to his fate. The whole kingdom groaned under his cruelties; rebellions broke out everywhere; and, in autumn 1567, Henry returned with 400 lances, the people immediately flocking to his standard. P.'s scanty and ill-disciplined forces were routed at Montiel (14th March 1569), and himself compelled to retire for safety within the town, whence he was treacherously decoyed and captured by Du Guesclin. He was carried to a tent, where a single combat took place between him and Henry, in which the latter would have been slain, had not some of his followers come to his aid, and slain the unfortunate P., 23d March 1569.

PETER I., ALEXIEVITCH, Czar of Russia, generally denominated PETER THE GREAT, was the son of the Czar Alexei Mikailovitch by his second wife, Natalia Naryskine, and was born at Moscow, 9th June 1672. His father, Alexei, died in 1676, leaving the throne to his eldest son, Feodor, P.'s half-brother. This prince, however, died in 1682 without issue, after naming P. as his successor, to the exclusion of his own full brother, Ivan. This step immediately provoked an insurrection, fomented by the children of the Czar Alexei's first marriage, the most prominent among whom was the grand-duchess Sophia, a woman of great ability and energy, but of unbounded ambition. Disdaining the seclusion customary among the females of the royal family, she showed herself to the *Strelitz* (q. v.), excited them to fury by an ingenious story of the assassination of her brother Ivan, and then let them loose on the supporters of P.'s claims. After a carnage of three days, during which more than sixty members of the most noble families of Russia were massacred, she succeeded in obtaining the coronation (July 1682) of Ivan and P. as joint rulers, and her own appointment as regent.

Up to P.'s coronation his education had been greatly neglected, but after this time he became acquainted with Lieutenant Franz Timmerman, a native of Strasburg, who gave him lessons in the military art and in mathematics; after which he had the good fortune to fall under the guidance of Lefort (q. v.), a Genoese, who initiated him into the sciences and arts of civilization, and by showing him how much Muscovy was in these respects behind the rest of Europe, influenced the whole of his future career. Lefort also formed a small military company out of the young men of noble family who attended P., and caused P. himself to pass, by regular steps, from the lowest (that of drummer) to the highest grade in it, rendering him all the while amenable to strict

discipline. This course of training, in all probability, saved P. from becoming the mere savage despot, which his brutal and passionate disposition, and indomitable energy inclined him to be; it also protected him from the jealousy of his half-sister, the regent Sophia, who, seeing him absorbed in military exercises and other studies, imagined that he had wholly given himself up to amusement. She, however, soon discovered her error, for P., contrary to her wishes, married (February 1689), by his mother's advice, Eudoxia Feodorovna, of the family of Lapoukin; and in October of the same year called upon his sister to resign the government. In the ensuing contest, P. was at first worsted, and compelled to flee for his life; but he was speedily joined by the foreigners in the Russian service, with a Scotchman named Patrick Gordon (q. v.) and the Swiss Lefort at their head; and the *Strelitz*, who were his antagonist's mainstay, flocking to his standard, she resigned the contest, and was shut up in a convent, whence, till her death, in 1704, she did not cease to annoy him by her intrigues. On October 11, 1689, P. made his public entry into Moscow, where he was met by Ivan, to whom he gave the nominal supremacy and precedence, reserving the sole exercise of power for himself. Ivan only enjoyed his puppet sovereignty till 1696. Though P. was all his life under the dominion of ungovernable passions and sensual habits, yet during great part of his reign he was so exclusively engaged in projecting and carrying out his schemes for the regeneration of Russia, that his gross animal nature had little opportunity of displaying itself.

His first care, on assuming the government, was to form an army disciplined according to European tactics, in which labor he was greatly aided by the valuable instructions of Gordon and Lefort, both of whom were military men, and had served in some of the best disciplined armies of Western Europe. He also labored to create a navy, both armed and mercantile; but at this period Russia presented few facilities for such an attempt, for she was shut out from the Baltic by Sweden and Poland (the former of whom possessed Finland, St. Petersburg (then called Ingria), and the Baltic provinces), and from the Black Sea by Turkey, which, extending along the whole of the north coast, had reduced that sea to the rank of an inland lake; leaving only the White Sea and the Arctic Ocean, with the solitary port of Archangel, available for the Russian navy. P. thinking the possessions of a portion of the Black Sea would best supply the required facilities of accessible sea-board and port, declared war against Turkey, and took (1696) the city of Azof at the mouth of the Don, after a long siege, which the ineffective condition of his newly-disciplined army compelled him to convert into a blockade. Skilled engineers, architects, and artillerymen were now invited from Austria, Venice, Prussia, and Holland; ships were constructed; the army further improved both in arms and discipline; and many of the young nobility ordered to travel in foreign countries, chiefly in Holland and Italy, for the purpose of acquiring such information as might be useful in the modernization and civilization of their country. They were ordered to take special notice of all matters in connection with ship-building and naval equipments. Others were sent to Germany to study the military art.

Not quite satisfied with this arrangement, P. was eager to see for himself the countries for which civilization had done so much, and which had so highly developed the military art, science, trade, and industrial pursuits; so after repressing a revolt of the *Strelitz* (February 1697), and dispersing them among the various provinces, he intrusted the reins of government to Prince Romonadofski, assisted by a council of three, and left Russia in April 1697, in the train of an embassy of which Lefort was the head. In the guise of an inferior official of the embassy, he visited the three Baltic provinces, Prussia, and Hanover, reaching Amsterdam, where, and subsequently at Saardam, he worked for some time as a common shipwright. His curiosity was excessive; he demanded explanations of everything which he did not understand, and to his practice of ship-building and kindred trades, he added the study of astronomy, natural philosophy, geography, and even anatomy and surgery. On receipt of an invitation from William III., king of England, he visited that country, and for three months, spent partly in London and partly in Deptford, labored to amass all sorts of useful information. While in England he received the honorary degree of D.C.L. from the university of Oxford. He left England in April 1698, carrying with him English engineers, artificers, surgeons, artisans, artillerymen, &c., to the number of 500, and next visited Vienna, for the purpose of inspecting the emperor of Austria's army, then the best in Europe. He was about to visit Venice also, when the news of a formidable rebellion of the *Strelitz* recalled him to Russia, which he reached by way of Poland, arriving at Moscow 4th September 1698.

General Gordon had already crushed the revolt, but these turbulent soldiers had so enraged P. against them by their frequent outbreaks, that he ordered the whole of them to be executed, even occasionally assisting in person on the scaffold. A few, however, were pardoned, and sent to settle at Astrakhan. The Cza-
